Preface

Awakening to acupuncture as neuromodulation permanently transformed my teaching and practice. In contrast to the early days of my acupuncture education, when I hungrily consumed and dutifully assimilated the belief systems required to adopt an energy-based viewpoint, I am no longer willing, nor ready, nor able to accept that acupuncture works through mystical, spiritual processes.

That is, I, like so many others, was taught that needling stirred an unseen electrical force (“Qi”) along invisible lines called “meridians”. When I learned, through mentors such as Deke Kendall, OMD, PhD, that the notion of acupuncture as “energy medicine” possessed neither a scientific nor historically accurate basis, I was shocked. How could this entire domain of acupuncture energetics result from a mistranslation of the Chinese word “Qi” in the early 20th century into “energy”, “for lack of a better word”?

After reviewing the evidence for and against an energy-based mindset in acupuncture, I found no other rational explanation for its effects other than through, primarily, the nervous system. Intellectual honesty forced me to let go of belief systems entirely and instead teach only truth based on science and evidence. Intellectual curiosity led me to find far more beauty and wonder in the anatomy of acupuncture than even the most elaborate fairy tales ever could.

What I discovered inspires me endlessly. The modern science of acupuncture replaces the myths and metaphors of yesteryear with detectable mechanisms and measurable outcomes. The neurovascular channels beneath the skin allow us to both literally and figuratively “connect the dots”, i.e., acupuncture points. The anatomical structures assembled at each site tell of their function and thus their effects.

Acupuncture then becomes more accessible, predictable, and sensible. Knowing which nerve pathways to target and why constitutes the cornerstone of noninvasive neuromodulation with acupuncture. Starting at the acupuncture point, one can follow a nerve’s centripetal course to the spinal cord, autonomic centers, and the brain. The nervous system’s responses to scientific medical acupuncture and related techniques thereby become clear, as fact replaces fiction.

Dedication

To my parents, Evelyn and Leonard, who brought me from formless to form, whose love and support gave me the strength and courage to find my own path.

To my brother, Larry, who inspired me to become not only a physician, but an osteopathic physician.

To the ancient Chinese, whose system of point and channels provides me endless amazement.

To Joseph M. Helms, MD, FAAMA, who flung the door to a life filled with discovery and meaning open wide.

To Deke Kendall, OMD, PhD, who caused me to question and rethink what I'd learned, allowing me to find deep fulfillment in a system of knowledge based on indisputable facts and realism.

To Joseph Wong, MD, whose clear message concerning the simple truths of neuroanatomical acupuncture stay with me to this day.

To Dave Mishlove, my life partner, who further cultivated in me a taste for authenticity, a penchant for integrity, and the strength to stand for truth amid staunch opposition.

Acknowledgments

This book and CD resulted from the extraordinary talents and commitment of several individuals, including:

The Visible Productions team, with special thanks to Stew Crawford who provided the computer programming for the CD and Amanda S. Almon, the medical illustrator and computer animator, who patiently worked with me to place the points and lines on the Visible Human anatomy images.

The folks at Teton NewMedia and Fiftysix Forty Design, including Sue Haun, creative director, whose expertise provided a book that is functionally and aesthetically pleasing, as well as Mike Albiniak, production manager, who worked with the project from start to finish to produce the internal layout. Special thanks as well to John Spahr, principal owner of Teton NewMedia, and Carroll Cann, the editor in chief, who saw value in the project and brought it to fruition.

Table of Contents

Section 1:: The Science of Acupuncture Neuromodulation

Chapter 1:: From Metaphors to Modern Medicine 3
Chapter 2:: Function Follows Form 13

Section 2:: Acupuncture Points and Channels

Chapter 3:: Introducing the Points and Channels 35
Chapter 4:: Locating Points on the Body 37
Chapter 5:: Acupuncture Safety 45

Section 3:: Twelve Paired Channels

Channel 1:: The Lung (LU) 51
Channel 2:: The Large Intestine (LI) 73
Channel 3:: The Stomach (ST) 119
Channel 4:: The Spleen (SP) 225

Section 1::

The Science of Acupuncture Neuromodulation

Chapter 1:: From Metaphors to Modern Medicine

Chapter Highlights

To know acupuncture, know anatomy.
To know neuromodulation, know neuroanatomy.
Neuromodulation explains acupuncture.

Neither mysterious nor nebulous, the wisdom of acupuncture unfolds clearly and readily through the study of anatomy – specifically, neuroanatomy. Acupuncture anatomy eliminates the need to substitute science with myths and metaphors. Scientific investigations have identified and verified many of the mechanisms by which acupuncture and related techniques benefit the central, peripheral, and autonomic nervous systems. Needling results in neuromodulation. Neuromodulation interlocks the events that take place from neuron to brain and back again – no belief systems required.

What Is "Neuromodulation"?

Neuromodulation is a process of engagement with neural structures that helps to normalize nerve function. It reduces excessive firing of nociceptive pathways and improves the ability of endogenous analgesic mechanisms to counteract spinal cord windup and dampen the perception of pain. Effective neuromodulation begins with proper point selection. Neuroanatomically specific acupuncture protocols pinpoint a patient's presenting problem according to where and how it is altering function along the neuraxis and its peripheral as well as autonomic extensions.

By considering the myriad manners in which neural discord mediates and perpetuates aberrant signals, a scientifically based medical acupuncturist outlines neural avenues (i.e., acupuncture points and channels) as well as stimulation methods (e.g., needling alone or the introduction of electrical or laser stimulation) by means of which to restore harmony and homeostasis.[113,114,115,116,117,118,119] That is, neuromodulation impacts sensory, motor, and autonomic activity based on the nerves targeted. The modality and settings selected (e.g., intensity, frequency, and mode of stimulation) further color the patient's physiologic response. The input flows throughout the matrix of the nervous system, from peripheral to spinal nerves, and spinal cord to brain. Brain sites affected include, but are not limited to, the reticular activating system, central autonomic network, the limbic system, brainstem, and the diffuse noradrenergic projection system.[135,142,143]

Neuromodulation began long ago with acupuncture and electrotherapy;[120,121] modern medicine has created more direct interventions through implanted units. Whether they prove more effective, cost-saving, and safer than manual acupuncture (MA), electroacupuncture (EA), or laser acupuncture (LA) requires research comparing techniques head to head.

As with acupuncture, the aforementioned implanted stimulators have benefited patients with pain,[122] epilepsy, neurogenic bladder secondary to spinal cord injury, fecal incontinence, constipation, erectile dysfunction, interstitial cystitis, and lower urinary tract dysfunction (incontinence, overactive bladder, urinary retention).[123] Additional conditions include chronic, refractory angina pectoris,[136] migraine,[137,138] spinal cord injury,[139] and complex pain problems.[140]

Curiously, those who utilize implanted stimulators often insert them along similar nerve pathways as acupuncturists address. For example, implant-driven nerve stimulation for refractory overactive bladder focuses on the posterior tibial nerve.[124,144,145] Acupuncture treatments for urinary voiding dysfunction also focus on the tibial nerve with points such as KI 3, KI 4, KI 5, and SP 6.[125]

Vagal nerve stimulation (VNS) for seizure control offers another example.[126,127,128,129] Electrodes implanted in the cervical portion of the vagus nerve interrupt or abolish experimentally induced motor seizures.[130] Acupuncturists may also choose points on the face or head that speak to the vagus nerve through crosstalk with the trigeminal nerve. Auricular acupuncture opens another door to neuromodulating vagal function. Veterinarian acupuncturists treating epilepsy in dogs may select ear points such as Shen Men, a point shown to have value for seizures in rats as well.[131,132,133] Auricular Shen Men falls into the zone supplied by the auricular branch of the vagus nerve (cranial nerve X, or CN X).[134] Thus, whether through implanted electrodes or inserted acupuncture needles, VNS modifies brain activity and can reduce seizure activity in some cases.[146]

"What If I Prefer to Think of Acupuncture as Moving Energy Instead of Stimulating Nerves? Does It Matter?"

Yes, it matters. Shifting the dialogue from metaphors and metaphysics to meaningful mechanistic concepts requires a thoroughly different premise. That is, a science-based medical acupuncturist needs a modern medical education along with instruction in myofascial palpation and non-invasive neuromodulation skills. Traditional Chinese Medical (TCM) schools and energy-based physician acupuncture courses continue to teach that acupuncture moves energy they call "Qi". The latter approach demands little verification but much belief. Even today, after having sufficient opportunity to "get it right", Traditional Chinese Medicine (TCM), metaphor-based practitioners are still struggling to validate their TCM diagnostic approach. In other words, even experienced TCM acupuncturists cannot come to agreement in their metaphoric analyses of patients in studies after studies.[147,148,149]

Lacking tenable processes, a metaphor-based acupuncturist has limited rational rationales to rely on when deciding on which points to choose. Treating a headache of the "Liver Yang Rising" or "Qi Disturbance" variety affords mostly abstract analysis of the cause and effect. Although the liver often receives much of the blame in causing TCM headaches, the physical liver usually has little to do with producing head pain in most people. Other assessments involving disturbances in Qi, Yang, Yin, and Phlegm also miss the mark by resorting to stand-ins, i.e., metaphors, in place of the actual anatomic, physiologic, and pathologic problems. As such, TCM point selection usually resorts to metaphorical solutions rather than novel protocols based on the patient's actual pathology.[150] Point selection relies more heavily on rote memorization of empirical protocols that give the practitioner minimal insight into why those protocols work from a biological perspective. To illustrate the difference between a metaphoric and scientific view of point effects, review the comparison in Table 1-1.

In contrast, a science-based medical acupuncturist treating head pain would, in practice, ordinarily strive to define the true cause, location, and myofascial relationships to the headache. Even if s/he defaults to a standard protocol for research or training purposes, the mechanisms by which acupuncture affects patients remain clear. To illustrate this, a group of Taiwanese researchers assembled a group of migraine sufferers in order to compare the value of acupuncture and a drug (topiramate) for prophylaxis of headache in chronic migraineurs.[151] Points selected for all sixty-six participants were the same: BL 2, GB 20, Taiyang, and Yintang. The rationale? "All of the selected acupoints were in the distribution of trigeminal and cervical dermatomes related to the trigeminal sensory pathway." Simple. Again, according to the authors, "It is assumed that a variable combination of peripheral effects, spinal and supraspinal mechanisms, and cortical, psychological or "placebo" mechanisms contribute to the clinical effects of acupuncture. Current theories suggest that migraine is a neurovascular disorder involving cortical spreading depression, neurogenic inflammation, and vasodilation. Sensitization and facilitation of pain transmission in central trigeminal sensory pathways may have a particularly important role in the development of CM (chronic migraine). A recent study suggests that acupuncture may have anti-inflammatory action via release of neuropeptides from nerve endings, including calcitonin gene-related peptide (CGRP), an important mediator of neurogenic inflammation and a potent dilator during migraine attack. We selected acupoints in the distribution of the trigeminal and cervical dermatomes because we postulated that an interaction between trigeminal and cervical nociceptive inputs to the trigeminocervical complex via acupuncture may inhibit trigeminal-vascular activation and thus may inhibit migraine attack….It is…important to understand what roles the peripheral as well as the central mechanisms have in CM patients after acupuncture treatment in future studies."

"Isn't Medical Acupuncture "Reinventing" Acupuncture Into Something It Never Was?"

Absolutely not. Admittedly, those already wedded to the metaphorical conceptualization brought to us by TCM may resist the need to learn the biological basis of disease, the anatomical basis of acupuncture, and the physiology of neuromodulation because they believe that a scientific approach to acupuncture is somehow new or foreign to China.[152] This is false. In fact, acupuncturists in China have been striving to practice scientifically for decades, with Zhu Lian making many important strides back in the 1950s.

That is, while the French were reworking acupuncture into an abstract system of "French Energetics" (see the section on George Soulié de Morant, below), Communist China created "The New Acupuncture" with the help of Zhu Lian, a physician trained in Western medicine who held several influential medical posts in China.[68] In keeping with the goal of the Communist Party leader Mao Tse Tung to integrate Chinese medicine with modern science, Zhu Lian, "strongly advocated the application of anatomy and western medicine in acupuncture". Zhu Lian pioneered the neuroanatomic basis of acupuncture well before Mao Tse Tung created Traditional Chinese Medicine (TCM) in the mid-twentieth century. In so doing, she unraveled many former mysteries through her extensive anatomical knowledge.[153] She saw acupuncture's influences as working to "stimulate and modulate the regulatory and control functions of nerve cells."[154]

Scientific research has only bolstered Zhu Lian's visions from the 1950s, as she hoped would happen. Even back then, however, she noted:

"The locations of the fourteen meridians roughly correspond to the anatomical distribution of excitors. Responses of the human body to acupuncture stimulation can basically be explained by neuroscience. Knowledge of higher nerves, however, was not available to ancient therapists, and hence discrepancies inevitably arose, because traditional acupuncturists, without a full understanding of neurology, simply formed associations between acupoints and internal organs."[155] That is, as aforementioned, non-scientific acupuncturists are frequently unaware of how their needling treatments actually work even today. Moreover, although Zhu Lian wanted acupuncture to survive and felt that exposing its factual, rational basis would allow it to do so, politics prevailed and TCM became increasingly engulfed by its murky metaphors.

When it moved west, TCM fell victim to even more myths; the American and European appetite for metaphysics unfortunately prevailed. The term "TCM" only adds to the confusion. That is, although the "T" stands for "Traditional", connoting a long-standing medical system, the Chinese Communist Party invented TCM only fifty years ago, during the years 1953-1956.[70,71] TCM is "a medical construct distinct to Communist China" and symbolizes "the standardized, government- created, institution-bound medicine that has existed in the PRC since 1956."[72] The first Outline of TCM became available in Communist China in 1958, published by the Beijing People's Health Publishers. It was designed to help fulfill the government's goal of having "doctors of Western medicine study Chinese medicine."[73]

In her book, *Chinese Medicine in Early Communist China 1945-1963,* Kim Taylor described the events surrounding the creation of TCM. "The formulation of a basic theory of Chinese medicine was an extraordinary feat, the ultimate in the manipulation of knowledge and its subsequent validation at the hand of politics."[74] She continued: "In general, the main aim of these "Basic Theories of TCM" was to simplify Chinese medicine and to reduce two thousand years of controversy and debate into one easy-access nutshell. This compromises every level of the physician's encounter with the patient, from examination to diagnosis through to prescription. Therefore this newly established theory of TCM simplifies the process of the identification of illness and the appropriate dispensation of drugs to a few basic steps. Such is the structured and measured packaging of a ready-to-use TCM designed for institutional consumption in twentieth- and twenty-first century Communist China."[75]

On the other hand, both in- and outside of China, science-based acupuncturists continued to pursue acupuncture demystification. As one practitioner in the mid-1960s stated:

> “If we wish to be taken seriously, and not to be confused with bone-setters or faith-healers, we must abandon the whole more or less Chinese mass of philosophy, cosmogony and mythology in which we have been entangled these forty years past. Let us clear the decks, and look at our problems without preconceived ideas. The study of the anatomy and physiology of the skin, and of the central and sympathetic nervous systems, the investigation of the physico-chemical and enzymic reactions in the body, all these should provide us with the means of solving the problem of what acupuncture really is and does.”[1]

Scientific acupuncturists agree that acupuncture depends on nerve function. In 1972, the Peking Acupuncture Anesthesia Coordinating Group reported, “About half of the known acupuncture points are located right over various nerves and the rest are within half a centimeter of one or another nerve. From this, the conclusion was drawn that acupuncture acts in fact on the nervous system, and it is through a nerve that the stimulus produced by needling or applying a mild electric current is transmitted to a certain part of organ of the body where it effects a cure or brings about a state of analgesia.”[21] The number of reports showing that acupuncture works via the nervous system began its rapid expansion in the mid-1970’s and has continued ever since.[5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20]

Indeed, if acupuncture worked by moving energy, not nerves, then severing nerves should not abolish the body’s reaction to needling. However, complete transection abolishes its effects and partial injuries minimize them.[2] This is not to say that acupuncture treatment should be avoided in cases of peripheral nerve, brain, or spinal cord injury, because needling therapy plays an important role (when given the opportunity) in helping patients recover from or contend with these conditions. Rather, it is intended to emphasize the central significance of the nervous system in medical acupuncture and related techniques.

In fact, by now, the neural basis of acupuncture has become so clear that certain authors are replacing the conventional alphanumeric naming system of acupuncture points and channels with nerve names – not remote and possibly imaginary organs as is now the case with commonly accepted nomenclature.[3] This idea,of revising and updating the acupuncture lexicon has a precedent; i.e., over thirty years ago, Dr. Patrick Wall, the co-developer of the gate control theory, felt that a new classification system based on acupuncture points and nerves was overdue.[4]

“You Say “To-May-To” and I Say “To-Mah-To”: Don’t Scientists and Energy-Based Acupuncturists Arrive at the Same Points?”

No, not always. Acupuncturists from either perspective may or may not select similar points. As indicated earlier, a TCM trained practitioner may view headache as Liver Yang dysfunction and select LR 3, LI 4, and GV 20. While the TCM rationale may involve statements about balancing Yin and Yang, expelling evil influences from the liver, or eliminating wind,[156] a neuroanatomic acupuncturists sees the process much differently. Both LR 3 and LI 4 relate to double arterial arch systems in the foot and hand, respectively. These vascular circuits receive heavy investment of sympathetic fibers. Thus, needle stimulation in their vicinity modulates autonomic function throughout the body. GV 20 impacts vagal function through crosstalk along trigeminovagal and cervicovagal routes. It also lies along the sagittal cranial suture overlying the sagittal venous sinus, thereby further impacting autonomic function and cerebral venous drainage. GV 20 overlies the galea aponeurotica as well; needle stimulation at this site aids in reducing occipitofrontalis muscle restriction that produces a “tension headache” type of pain. For migraine headaches per se, a scientifically based medical acupuncturist might add points to address trigeminal nerve dysfunction, as illustrated above. The weight of evidence supporting a neuroanatomic approach emphasizes the importance of selecting points according to actual patient pathophysiology. To wit, chronic migraine sufferers who received acupuncture at points supplied by the trigeminal nerve experienced a significantly larger reduction in moderate/severe headache days than did those in the topiramate group with far fewer side effects.[157]

Even if a metaphoric practitioner chose the same points as the science-based practitioners did in the migraine study just described, an accurate understanding of the ways in which acupuncture improves acupuncture’s legitimacy. Quoting Kendall: “Why does anyone care whether Chinese anatomy and physiology are explained as energy flowing through meridians, or by the circulation of blood, nutrients, other vital substances, and vital air (qi) through the vascular system? The answer to that lies in the moral obligation of every practitioner to provide each patient with the latest medical understanding available. The need to continually search for the truth is the most fundamental principle of science and medicine. If the functioning of the human body cannot be understood under normal physiological conditions, then there is little hope of knowing how to treat it when disease conditions exist. Research so far show that the true concepts of Chinese medicine operate under known physiological principles, involving the complex organization of the neural, vascular, endocrine, visceral, and somatic systems, sustained by the circulation of nutrients, vital substances, and oxygen from vital air.”[22]

Why Researchers Need to Recognize the Scientific Basis of Acupuncture

Ongoing research in Asia and on other continents focuses on measurable, physiologic changes due to acupuncture, not the vague nuance and mysticism so commonly found in Western acupuncture literature. According to Kendall, the abstract, unscientific idea that acupuncture has an immaterial basis “has kept Chinese medicine on the fringes of conventional care since the 1930s and 1940s”.[23] Countless research dollars and hours disappear in the misguided mission of searching for invisible, energy-conducting pathways, yielding little to benefit patients and further the understanding of acupuncture.[24,25,26,27,28,29,30,31,32,33,34,35,36,37,38,39,40,41,42,43,44] Moffet appears to concur, criticizing methodologic approaches that cling to “unsubstantiated traditional acupuncture theories”.[158] He continues: “When comparing acupuncture interventions [e.g., verum and sham approaches], investigators should offer a biologic rationale to support a hypothesis that the exposures are truly different. A clinical trial with indistinguishable exposures is a poor use of resources…If the acupuncture exposures are indistinguishable, then the investigators have failed to control for the placebo effect." Many examples of inadequate sham selection exist in the medical literature. Most commonly, researchers fail to consider the neuromodulatory overlap that happens when verum (real acupuncture) and sham (placebo acupuncture) excite similar nerve pathways.

Why Today's Clinicians Need to Espouse a Rational Premise for Acupuncture

The demystification of acupuncture in no way diminishes its brilliance. Rather, identifying the structure-function relationships between acupuncture point anatomy and clinical indications brings acupuncture closer to its ancient roots than do musings about energetic evolutions. Clinging to outdated jargon may, in fact, prevent patients from seeking appropriate medical attention.[45,46,47,48,49,50,51,52,53] For example, informing a patient complaining of chest pain and shortness of breath that they have "Qi and Yin Deficiency"[54] may have been adequate during the Han dynasty, but not today. Rather, prompt medical attention is in order. Similarly, "Liver Fire blazing with Phlegm-Heat" could indicate Graves' disease or even papillary thyroid cancer, and require treatments other than, or in addition to, acupuncture.[55] Patients with "Kidney Yang Deficiency"[56] may actually be experiencing adrenal insufficiency or crisis. One should neither delay nor preempt further diagnostic workup and appropriate medical intervention by seeking to balance an abstract Yin and Yang.[57,58,59,60]

Why, then, do schools and postgraduate courses promote acupuncture metaphysics? Perhaps too few instructors and students have learned about the actual origin of the energy-meridian misconception. Not thousands of years old, not even hundreds, the Qi-as-energy myth was born less than a century ago, a brainchild of a French citizen residing in China by the name of George Soulié de Morant.

George Soulié de Morant's Hope of Acupuncture Metaphysics

No convincing evidence exists that acupuncture works by pushing energy through invisible transmission lines.[61] As the inventor of the energy-meridian concept, George Soulié de Morant, stated, "Having observed the existence of "something" that passes through a meridian when a point is stimulated, the ancients gave this fluidity, this flux, the name qi, which we translate, for lack of a better word, "energy".[62] Because Soulié de Morant lacked medical training and in that he wanted to present Chinese medicine in ways he thought his French audience would understand, he introduced his own bias about how acupuncture worked, i.e., through unseen energies moving through intangible pathways.[63]

Living within the European cultural and philosophical context when he wrote his landmark text, *l'Acuponcture Chinoise (Chinese Acupuncture)*, Soulié de Morant relied on his readers believing his claim of a metaphysical basis for acupuncture. After all, the concept of "élan vital", or immaterial life force, had spread and grown popular throughout Europe. Élan vital was to have produced and shaped all life; notions about this vivifying impulse permeated the philosophy of that era.[64] Yet, not all were convinced; the British biologist Julian Huxley once commented that élan vital offers no better an explanation of life than élan locomotif accounts for the motion of a train.[65]

Nor was Soulié de Morant's book translator, Paul Zmiewski, convinced of the author's claims. Zmiewski noted in his introduction, "While ideas found in modern English texts are often expressed in English words derived from *l'Acuponcture Chinoise,* these words do not always mean what was meant in the classic works upon which *l'Acuponcture Chinoise* is based."[66] About Soulié de Morant's selecting the term "energy" for "Qi", Zmiewski wrote, "At the beginning of the twentieth century concepts like "human energy" were referenced in dictionaries and were considered valid matters for scientific inquiry. Many nineteenth century ideas of nature were still broadly regarded as truths. Today, however, the scientific era that had just begun when Soulié de Morant chose to use the term "energy," has left that word with new and different associations in both popular and scientific writing." As such, even Soulié de Morant's own idea behind the Qi translation has undergone an evolution, independent of its original meaning in ancient China.

Reinventing acupuncture into an "energy medicine" required that Soulié de Morant downplay the importance of anatomy and physiology in Chinese medicine.[76,77] He did not include *The Yellow Emperor's Classic of Internal Medicine* among his translations. Had he done so, as Kendall indicated, he would have found that the early Chinese physicians living between 600 and 300 BCE had compiled "surprisingly accurate and detailed information on the human body, with some of the ideas clearly equivalent to those of modern Western physiology."[78] Unfortunately, this disregard of acupuncture anatomy and physiology promulgated by Soulié de Morant led to an ensuing disinterest by future acupuncturists in the material foundation of acupuncture.

Some even assert, although incorrectly, that ancient Chinese investigators never performed anatomical investigations.[79] Kendall offers two possible reasons for this misconception.[80] First, historians may have assumed that since Confucian teachings proscribed postmortem dissections, they were not performed. Alternatively, some believe that since ancestor worship pervaded the culture especially strongly many centuries ago, those dissecting the body after death would have likely incurred a great degree of ancestral displeasure. Nevertheless, postmortem autopsy likely occurred long before Confucius existed (551-479 BCE), and still took place during his lifetime. Furthermore, the prohibition on autopsies that occurred in some dynasties happened several hundreds of years after the studies mentioned in the Nei Jing were already documented. Information encountered in the Nei Jing attests to the fact that anatomical dissections took place, producing insights into the size, weight, and capacity of all internal organs.[81]

Even the acupuncture channels (jingluo), which many now

Table 1-1

Metaphorical "Actions" of LI4 stimulation, according to Chinese Medicine[85]	**Effects of LI4 stimulation, according to Scientific Studies***
Autonomic Influences	
"Regulates the defensive qi and adjusts sweating"	Both high and low frequency electroacupuncture (EA) stimulation of LI 4 (with SI 3) produced short-term cooling.[86] Manual and EA stimulation of LI 4 produced long-lasting warming (indicating a sympatholytic effect) after the transient, segmental increase in sympathetic activity that caused a localized, short-term cooling.[87] Acupuncture at LI 4 caused an increase in palm temperature, probably due to cutaneous vessel dilation.[88] EA at LI 4 selectively activated the sympathetic, but not parasympathetic, nervous system. In so doing, the rhythmic micturition contraction cycle lengthened and urine excretion increased, as did renal sympathetic nerve activity and blood pressure. These results indicated that EA at LI 4 may benefit patients with hyperactive bladder problems.[110] EA at LI 4 and LI 11 increased both pain thresholds and muscle sympathetic nerve activity.[111]
Analgesia	
"Expels wind and releases the exterior"; "Regulates the face, eyes, nose, mouth and ears"; "Activates the channel and alleviates pain"	EA diminished dental pain perception; high intensity EA was most effective.[89] Naloxone failed to reverse elevated pain thresholds induced by EA, indicating that non-opioid transmitters are involved in dental analgesia.[90] Nitrous oxide blocked the effects of electrical stimulation at LI 4.[91] Needle manipulation at LI 4 significantly increased pain pressure thresholds.[92] Unilateral EA at LI 4 (and LI 11) transiently inhibited the motoneuron pool in the extensor digitorum communis muscle of the contralateral arm, suggesting that EA operates by central effects, instead of or in addition to peripheral influences.[93] Transcutaneous electrical nerve stimulation (TENS) at LI 4 reduced the sensation of pain but not vibration.[94]
Effects on the Central Nervous System	
"Restores the yang" (i.e., "for the treatment of collapse of yang characterised by loss of consciousness, aversion to cold, cold counterflow of the limbs, purple lips etc.")	Manual and EA stimulation of LI 4 produce differential brain activation. Manual needle manipulation caused prominent functional magnetic resonance imaging (fMRI) signal decreases in the posterior cingulate and superior temporal gyrus as well as the putamen/insula. EA caused signal increases in the precentral gyrus, the postcentral gyrus/inferior parietal lobule, and the putamen/insula.[100] Somatosensory evoked potentials obtained after EA at LI 4 (which activates radial nerve fibers) differ markedly from those obtained after EA at the median nerve.[101] Needle manipulation at LI 4 modulated activity in limbic and subcortical gray structures of the brain, as shown by fMRI.[102] Brain magnetic fields measured by SQUID (Superconductive Quantum Interference Device) after acupuncture at LI 4 revealed changes in the biomagnetic fields relating to the projection areas of the face and jaw.[103] LI 4 stimulation caused a significant increase in the latency and decrease in the amplitude of peaks reflecting primary cortical afferent activities.[104] Needle manipulation of LI 4 activated the hypothalamus, supporting the notion that this classical analgesic point works at least in part to reduce pain through hypothalamic activation.[105,106] Manual acupuncture to LI 4 activated both somatosensory cortical areas and the periaqueductal gray.[107] High-frequency EA at LI 4 induced specific electroencephalographic (EEG) modulation of Theta activity in the midline frontal region. This may reflect reduced activity in the anterior cingulate cortex, resulting in antinociception.[108] Needle manipulation at LI 4 activated structures in the descending antinociceptive pathway (i.e., the hypothalamus and nucleus accumbens) and

Effects on the Central Nervous System, Continued

	deactivated multiple areas in the limbic system associated with pain (rostral part of the anterior cingulate cortex, amygdala formation, and hippocampal complex), indicating ways in which endogenous pain modulation circuits in the brain may function.[109] EA at LI 4 and LI 11 caused a positive spread of activation across the spinal cord segments C5 to T1, with peak activity taking place at C7. Activation occurred at both the dorsal and ventral parts of the cord, indicating that LI 4 and LI 11 can indeed modulate specific spinal cord regions. This study suggests that individuals with sensorimotor deficits arising from these spinal segments may benefit from acupuncture at these points.[112] Magnetic stimulation of LI 4 affected specific brain areas, such as the anterior cingulate cortex, that differed from those influenced by a "mock" point, also on the hand.[159]
Obstetrical Influences	
"Induces labour"	Acupuncture at LI 4 suppressed uterine contractions induced by oxytocin in pregnant rats.[95] Acupuncture at LI 4 inhibited the expression of the cyclooxygenase-2 (COX-2) enzyme and reduced uterine motility significantly.[96] Acupuncture at LI 4 (and SP 6) helped ripen the cervix at term and shortened the time interval between estimated date of confinement (EDC) and delivery.[97] Ice massage on LI 4 reduced labor pain during contractions.[98] Acupressure at LI 4 and BL 67 reduced labor pain during the active phase of the first stage of labor, but did not significantly affect uterine contractions.[99]

call "meridians", originally pertained to actual blood vessels and their accompanying nerves. This makes sense given that acupuncture started as bloodletting. In his essay, "Bloodletting in early Chinese medicine and its relation to the origin of acupuncture", Epler wrote, "The vessels are organic structures, not functional pathways as they were later to become, blood is a fluid, and pneuma is, certainly in part, a material substance, not the "energy" it was later to become."[82] In his *Dao of Chinese Medicine,* Kendall noted, "Replacing the blood vascular system with nonexistent meridians is the single greatest translation error to befall Chinese medicine."[83]

In the context of his nonmedical background and the times in which he lived, Soulié de Morant's mistranslation of "Qi" as "energy" seems forgivable. What is less "okay" is the perpetuation of this mistranslation by educators today, instead of acknowledging the truth, i.e., that in the acupuncture matrix originally referred to the vascular network with its circulating gases, cells, and nutrients. Forcing acupuncture to stay stuck inside a mystique and superstition it long outgrew binds its natural development like foot-binding did to maturing anatomy, unable to reach its full expression.[67] In both the metaphor-based acupuncture model and the torturous practice of foot-binding, the ideal represented a culturally repressed esthetic as opposed to reality, a system of sustained immaturity weakened by those who curtail proper expansion and innate capacity.

How do acupuncture researchers, educators, and clinicians undo the damage done by this prodigious misstep in acupuncture's history? Like most recovery programs would insist, those addicted to the energy-meridian paradigm need to begin by telling the truth. The time is now to set the record straight and acknowledge the rational, anatomic, and scientific basis of acupuncture.

Summary

The specificity and multiplicity of verifiable and reliable outcomes obtained by scientifically studying a point such as LI 4, as outlined in Table 1-1, illustrate the advantages of allowing acupuncture to mature into a modern medical treatment based on neuromodulatory actions. The steps toward manifesting this transformation first require a comprehensive grasp of neuroanatomy as it relates to acupuncture points, thus the purpose of the book.

Chapter 2:: Function Follows Form

Key Points

The science of neuromodulation endows acupuncture with a factual, rational basis and a neuroanatomic framework. Together, the science of neurophysiology and the instructional attributes of anatomy inspire cogent and sophisticated protocols for scientific, medical acupuncture and related techniques (SMARTs).

The outcome of a neuromodulation treatment depends on the regions, types, and number of nerves activated, as well as the method of stimulation selected.

Acupuncture stimulation most immediately affects one or more of the three types of peripheral nerves:

- **Motor**
- **Sensory**
- **Autonomic**

Stimulation methods involved in medical acupuncture include but are not limited to:

- **Dry needling, otherwise known as manual acupuncture (MA)**
- **Electroacupuncture (EA)**
- **Laser acupuncture (LA)**
- **Acupressure**

Comprehensive treatment entails three steps:

- **Determine the problem; understand its nature, location, and origin**
- **Identify neural avenues that produced and perpetuate the problem; consider how neuromodulation can affect these or other nerves to undo the damage and promote recovery**
- **Influence nerves from the peripheral, central, and autonomic nervous systems**

Understand the Function of Acupuncture Points through their Anatomy (Form)

For ages, philosophers and physicians have recognized the inseparable partnership of anatomy and physiology.[282,283] Investigating ways in which form meets functions in acupuncture illuminates the wealth of wisdom layered into each needling site. Systematic analysis of the local anatomy uncovers the effects of stimulating a point with delightful directness. Metaphorical medicine then dissipates and dissolves like fog in the morning after a night of rain; science, like the sun, burns away clouds of uncertainty with beams shining light on the ways in which acupuncture actually works.

Not merely an intellectual exercise, the anatomy of acupuncture impels clinicians to ask more precise questions about their patients and informs their thinking fingers during myofascial assessment of them.

In the examination process, one asks, “Is this where it hurts?” as the examiner’s hands seek to find tension and tenderness. Three-dimensional anatomy reveals underlying reasons for numbness and weakness by disclosing regions where muscles course over and around nerves. Structure and function show why tension and pain result and where they require intervention. In other words, myofascial impediments may impair nerve communication. Nerve entrapment due to myofascial restriction, fascial bands, or scar tissue may block a signal from reaching its destination or alter its message. Thorough, informed palpation frequently allows the medical acupuncturist to detect sites of nerve compression through findings of tissue tension and tenderness.

Nerves that have suffered from excessive or prolonged pressure, overstretching, or starvation from of insufficient oxygenation and nutrients through poor circulation can become neuropathic. Neuropathic nerves transmit erroneous information. Like trying to carry on a conversation along a poor cell phone connection, injured nerves relay distorted or interrupted messages. Depending on the nerve’s job in life and specialization, the patient may experience alterations in sensory, motor, and/or autonomic message delivery. As a result, instead of accurately reporting information about position sense, pain, touch, and so on, neuropathic nerves may cause the patient to feel pain instead of touch or pressure (allodynia) or find a mildly uncomfortable stimulus to cause unbearable pain (hyperalgesia).

Dysfunctional muscle tissue and related neural networks produce myofascial trigger points. Myofascial trigger points, a nearly ubiquitous phenomenon, can cause peripheral nerves to become neuropathic and inflamed due to their chronic nature and tendency to worsen and multiply if left untreated. Attending to trigger point dysfunction with neuromodulation through needling and related techniques is a major process by which acupuncturists benefit their patients.

Where do trigger points occur? One finds most myofascial trigger points in the middle of the muscle belly where the majority of muscle spindles and motor endplates lie as well as in the myotendinous junctions, occupied by Golgi tendon organs. Due to their profound roles in producing and perpetuating pain and dysfunction, these sites of highly specialized nerve endings in muscles and tendons become critical targets for acupuncturists. For example, an acupuncturist may select Gallbladder 20 and 21 (GB 20, GB 21) for myofascial pain the shoulder-neck region. GB 20 is located at the myotendinous attachment of the upper portion of the trapezius, and GB 21 lives in the middle of its muscle belly.

On a broader scale, truncal anatomy (as shown in the layered as well as cross-sectional anatomy in the upcoming chapters) bespeaks how form and function affect both soma and viscera. How do the nerves occupying BL 23 on the body wall affect the kidney? The answer becomes clear when considering the spinal segmental nerve supply that both sites share. Interneurons in the spinal cord yoke neural traffic from the small of the back with signals stemming from the depths of the abdomen and pelvis. Palpation of the paraspinal muscles along the entire back reveal results of aberrant neural traffic from facilitated spinal segments in the form of tissue tenderness, tension, and restriction. These findings of myofascial dysfunction along certain spinal segments serve to raise our awareness of potential somatic and/or visceral disturbances in the body realms subserved by this spinal cord “real estate”. This then informs both our diagnosis and treatment of the patient.

Layered and cross-sectional anatomy images also uncover structures beyond our fingers' reach. The bony calvarium keeps us from touching the brain and its vessels. Through the translucent skull in the Visible Human images in this book, connections between channels and vessels such as the Governor Vessel (GV) and the superior sagittal venous sinus remind us of the original, vascular basis of acupuncture as a whole and the eight singular vessels in particular. The Governor Vessel's counterpart, Conception Vessel (CV), represents the vena cava, whose relationship to the overlying central CV on the surface of the anterior (ventral) trunk now makes sense. Clinically, one may detect expansions of the often forgotten collateral venous drainage pathways when the vena cava obstructs, making the connection between deep, interior processes and the body surface, visually striking. In this way, channels' interconnections from deep to superficial and from one to another bring to life the meaning behind the metaphor in ancient writings on acupuncture. Today, scientific pursuits elaborate on these early insights and draw detailed descriptions of how acupuncture and related techniques influence form and function. Let us begin at the point-stimulus juncture.

The Needle-Tissue Interface

In acupuncture, the "rubber meets the road" at the needle-tissue interface. Like tires on pavement, the acupuncture needle must engage with its surroundings in order to gain traction and cause change. When rotated, the acupuncture needle attracts and pulls on collagen and possibly muscle fibers, causing them to grab its shaft. This bond between metal and fibers forces the tissue to respond and initiates a conversation with neighboring nerves, fascia, and fibroblasts.

The message spreads to nearby cells, culminating in a wave of tissue deformation and neural discourse that travels beyond the immediate vicinity. If the needle has reached muscle, the impact of treatment intensifies.[284] Nerves ferry information about the event in both an orthodromic (toward the spinal cord) and antidromic (toward the nerve's terminals) direction along a channel.

The Peripheral Nervous System's Subspecialists: Nerve Endings

In addition to proprioceptors such as muscle spindles that respond to changes in length and Golgi tendon organs that assess tension, a number of other receptors in tissue act as an interface between the external environment and the nervous system. This allows the acupuncturist to employ treatments that adjust or alter sensory input with the aim of supporting the healing process. Knowing the types of nerve endings typically found at acupuncture sites gives the medical acupuncturist a better understanding of the likely outcome of stimulating those points. For instance, if the acupuncture point overlies a blood vessel, a needle tugging on fascia nearby may stimulate its nervi vasorum (vascular nerves). These adrenergic fibers control vessel wall tone. As such, the effects of needling this site could involve neuromodulation of circulation and blood pressure regulation. An example of this type of point is Lung 9 (LU 9).

Acupuncture Points as 3-D Structures

Acupuncture points are three-dimensional events, not static dots on the skin surface. This fact converts the rather simple activity of inserting a needle into a multilayered excursion into a patient's bodily habitus. The dialogue between form and function deepens as the needle traverses skin, then fat, then fascia, muscle, and maybe periosteum. At each level, tissue resistance to the needle tip's travel tells of the tension and tone it encounters. Too much or too little of either tension or tone can signify dysfunction and/or disease.

When the treatment involves trigger point deactivation, attention to tissue texture and tension changes becomes paramount. Isolating a patient's source of pain precedes its elimination. When patients exclaim, "That's it! That's where the problem is!", it confirms palpatory findings. Re-examination through palpation and patient feedback after dry needling verifies or denies that the trigger point has responded. Trigger point deactivation serves as a profound example of the dynamism between form and function that takes place through the needle conduit.

Nerve Chat

Nerves serve as the body's social medium. Not shy, they publicize their messages broadly, speaking to everyone who will listen, whether organs, glands, vessels, muscles, fascia, and other nerves. The messages they send may be momentary, such the faint brush of a breeze going by, or lifelong, as in the case of childhood onset Crohn's disease. Similarly, their emotional and somatic sequelae may place a temporary or permanent imprint, depending on how many signals they send each time they complain, and how long their upset lasts. The "complaint department", i.e., the central nervous system (CNS), responds to neural reports of pain and distress with attempts to alleviate them. If unsuccessful, neural plasticity makes the CNS a codependent partner by prolonging the problem, leading to hyperalgesia, allodynia, inflammation, sympathetic hyperactivity, muscle tension, and long-term stress.[285]

By the time a patient presents for treatment, pain and dysfunction have usually existed long enough to cause a collection of problems. This behooves the medical acupuncturist to develop a neuromodulatory intervention that addresses several levels. It is therefore not enough to ask how the chief complaint started and where it hurts, but also why is it continuing and how does it express itself in the structure (myofascia, posture, joint mobility), viscera (organ, metabolic, and glandular activity), and emotions (anxiety, depression, withdrawal, confusion)? Has the problem not only influenced function, but is it also now altering form?

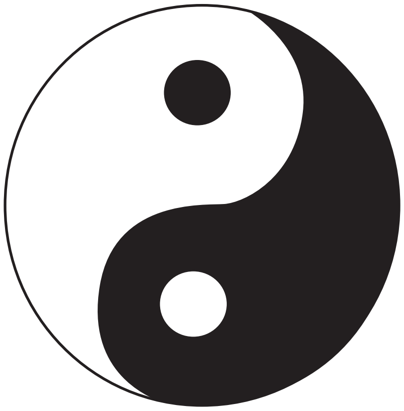
Acupuncture neuromodulation should, to the degree possible, address each aspect of a patient's discord; i.e., its central, peripheral, and autonomic components. This likely will require several treatments.

Acupuncture Neuromodulation

Neuromodulation is a naturally occurring phenomenon, allowing the body to respond and adapt to endogenous and exogenous stimuli. It provides for the protection, homeostasis, and repair of the organism.[2,3,4,5,6] Sometimes, though, autoregulatory processes either falter or fail. Acupuncture is simply a somatosensory input that assists the body in making the neuromodulatory changes necessary to regain health and homeostasis.[7]

Acupuncture neuromodulation signals initiated near needling sites propagate along nerves toward the CNS.[1] Connections at the spinal cord can course in several directions. The cord may 1) send efferent signals back out to the periphery (leading to antidromic activation of free nerve endings at the site of needling), 2) loop into related visceral neural networks and alter internal organ function in a spinal segmental manner, 3) foster endogenous opioid release in the dorsal horn of the spinal cord to reduce spinal facilitation, or "wind-up", and block pain, and/or 4) proceed to higher centers in the brain, altering neural and hormonal functions. When these impulses arrive at the brain, they influence activity there as well, usually in a beneficial manner.

Exactly how the body responds and which parts of the body react depend on the nerves stimulated.[8] However, the body's pre-needling state may also influence outcomes.[9,10] For example, the point ST 36 treats both diarrhea and constipation, depending on pre-treatment gastrointestinal motility status.[11,12] In this way, the same point can either "quiets things down" in cases of hyperfunction, or "fire them up" in hypofunction.



The Tai Ji symbol illustrates the balanced, intertwining, and evolving relationship between Yin (black) and Yang (white), with elements of the complementary partner held by each component (represented by the small circles).

Yin and Yang in the Modern Era

TCM terms such as "Yang Excess" and "Yin Deficiency" can now be viewed as sympathetic hyperfunction or parasympathetic hypofunction.[13,14] Disease states that illustrate Yang Excess include hyperthyroidism and acute fever. "Deficient Yin" describes parasympathetic hypofunction, most dramatically depicted by toxic exposure to anticholinergics, or parasympathetic antagonists. In this case, the victim turns "red as a beet, blind as a bat, dry as a bone, mad as a hatter, and hot as hell".[15]

Conversely, "Excess Yin" connotes just the opposite, i.e., parasympathetic hyperfunction and/or sympathetic hypofunction. One might even see a concatenation of autonomic disruption, as in cluster headaches. These patients exhibit both sympathetic hypofunction, manifesting as miosis and ptosis, along with parasympathetic hyperfunction, with rhinorrhea and lacrimation.

Table 2-1 Sympathetic and Parasympathetic Functions[18,19]

Organ	Effects of Sympathetic System (Yang)	Effects of Parasympathetic System (Yin)
Adipocyte metabolism	Causes lipolysis	---
Adipocyte, brown	Causes heat production	---
Adrenal medulla	Causes adrenaline/epinephrine (80%) and noradrenaline/norepinephrine (20%) secretion	---
Arteries in cranium	Vasoconstricts	May vasodilate
Arteries in erectile tissue (helical arteries and sinusoids in penis and clitoris)	Vasoconstricts	Vasodilates
Arteries in heart[20] (coronary arteries)	Transient vasoconstriction, followed by vasodilation	Some vasodilation
Arteries in skeletal muscle	Vasoconstricts (via adrenergic fibers) under resting tone and vasodilates large arteries (via cholinergic fibers) during exercise	---
Arteries in skin and mucosa of face	Vasoconstricts	Vasodilates
Arteries in skin of trunk and limbs	Vasoconstricts	----
Arteries in viscera	Vasoconstricts	----
Esophagus	Motility decreases Sphincters contract	Motility increases Sphincters relax
Eye	Pupillary dilator muscle dilates pupil Contracts tarsal muscle (lifts lid) Ciliary muscle relaxes for far vision	Pupillary sphincter muscle contracts pupil Contracts ciliary muscle
Gallbladder and biliary ducts	Relaxes	Contracts

Table 2-1 Sympathetic and Parasympathetic Functions, Continued

Heart	Increases heart rate Increases atrial and ventricular contractility	Decreases heart rate Decreases atrial contractility
Intestines	Motility decreases Sphincters relax Secretion decreases	Motility increases Sphincters contract Secretion increases
Kidneys	Arterioles constrict	Arterioles dilate
Lacrimal gland	---	Secretes
Liver metabolism	Causes glycogenolysis, gluconeogenesis	---
Lungs	Relaxes tracheobronchial muscles	Contracts tracheobronchial muscles Increases mucous secretions from bronchial glands
Lymphoid tissue	Reduces activity (e.g., of natural killer cells)	---
Nasopharyngeal glands	---	Secretes
Pancreas[21]	Increases circulating glucose Inhibits insulin secretion from the islet beta cells Constricts pancreatic blood vessels	Increases insulin secretion Dilates pancreatic blood vessels
Piloerector muscles	Contracts	----
Pilomotor muscles of the skin	Causes contraction	---
Pineal gland	Increases synthesis of melatonin	---
Prostate, seminal vesicle	Contracts	---
Salivary glands	Weak serous secretion (submandibular salivary gland) Sparse, thick secretion	Profuse serous secretion
Splenic capsule	Contracts	---
Stomach	Motility decreases Sphincters contract Secretion is inhibited	Motility increases Sphincters relax Secretion increases
Sweat glands of the skin	Induces profuse secretion	---
Thyroid gland	Becomes stimulated	
Ureter	Decreases ureteric tone and motility	Increases ureteric tone and motility
Urinary bladder	Relaxes detrusor muscle (small amount) Increases internal sphincter tone and trigone	Contracts detrusor muscle Relaxes internal sphincter tone and trigone
Uterus	Contracts pregnant uterus Relaxes or contracts the non-pregnant uterus	---
Vas deferens	Contracts	---
Veins	Vasoconstricts	---

Instead of relying on abstract concepts of Yin and Yang, studying the autonomic nerve supply to organs and glands yields insights into ways in which illness manifests neurophysiologically. This then opens the door to acupuncture neuromodulation by outlining neuroanatomic expressways that revise neural traffic. Table 2-1 compares the complementary actions of the two limbs of the autonomic nervous system (ANS), designated by tissue or organ. Most viscera receive dual innervation from both sympathetic and parasympathetic limbs of the ANS.[17]

How Acupuncture Points Affect Internal Organs

While needling neuromodulates nerve activity in local structures through direct effects on tissue, its broader, homeostatic value results from reflexes in the spinal cord and brain.

The Spinal Cord Connects the Soma with Viscera

One of the most salient depictions of how the ancient Chinese linked anatomy (structure) with physiology (function) comes from the Back Shu and Front Mu points. These twelve pairs of points (one Back Shu and one Front Mu for each organ) act upon certain sections of the spinal cord. Their associated spinal cord levels house interneuronal connections connecting pathways that produce reflexes between acupuncture points on the body surface (soma) and internal organs (viscera).

The paraspinal Back Shu points run along the inner Bladder channel from the thorax to the sacrum. The Front Mu points occur on the lateral or anterior aspects of the trunk and generally receive nerve supply from spinal cord segments that overlap with those of the Back Shu points.[122] Back Shu points receive innervation from the dorsal (posterior) ramus of a spinal nerve, while the Front Mu points occur along dermatomes of the same, or neighboring, spinal nerve, supplied by either the lateral or ventral (anterior) ramus.

Because each organ and its associated pair of Back Shu and Front Mu points often share innervation from similar or overlapping spinal cord levels. In the spinal cord, neurons in the deep layers of the dorsal horn receive convergent input from somatic structures and viscera.[124]

Unhappy nerves arise from unhappy organs and body wall structures such as tense or painful muscles and fascia. Nociceptive neurons, when activated, bombard the spinal cord with tales of woe.[123] They become more excitable and fire more readily in response to stimuli. This phenomenon of central nervous system excitation is known as "wind-up" or "facilitation".[125,126] Sensitized neurons will, in some cases, trigger impulses spontaneously, long after the initiating insult has ceased causing tissue damage or irritation. Cells receiving muscle input in the intermediolateral gray column of the spinal cord, where preganglionic autonomic cell bodies reside, become hyperactive as well, propelling a loop within the sympathetic system that participates in the process of referred hyperalgesia.[127]

Central sensitization amplifies output to both visceral and somatic structures. Sympathetic efferent neurons in the thoracic and lumbar spinal cord segments join in this dysfunctional dance. Muscles supplied by sensitized segments become tense due to increased output through somatic motor neurons, causing sustained muscle contraction. This engenders myofascial dysfunction and trigger points.[128] Heightened sympathetic tone drives vasoconstriction and edema; it also amplifies tissue tenderness and texture changes.[129,130,131,132,133]

Organs receiving neural input from "wound up" spinal segments experience decreased perfusion due to sympatho-excitation.[134,135] Conceivably, compromised blood flow in an organ could, over time, lead to insufficiency or, ultimately, failure in that structure. In the kidney, for example, activated renal sympathetic nerves reduce renal blood flow, increase renin secretion, and increase renal tubular sodium reabsorption.[136] Should counteracting autoregulatory controls falter or prove insufficient, hypertension may result.[137]

In practice, an acupuncturist palpates the entire group of Back

Table 2-2
Sympathetic Input to the Back Shu and Front Mu Points[157,158]

Organ	Sympathetic Preganglionic Levels[159,160,161,162]	Site of Synapse of Pre- and Post-Ganglionic Sympathetic Neurons[163]	Course of Nociceptive Afferent Pathways into the Central Nervous System*[164]	Associated Back Shu Point and Vertebral Level**	Associated Front Mu Point and Dermatome Level
Lungs (including the trachea and bronchi)	T2-T7, to upper thoracic sympathetic ganglia	T2-T6 sympathetic ganglia	Afferents travel with the sympathetics to the dorsal root ganglion neurons from T2-T7 and the vagus nerve to the nucleus tractus solitarius (NTS) in the medulla	**BL 13;** T3	**LU 1;** C4,T2
Pericardium	T1-T5, to upper thoracic and cervical sympathetic ganglia	All cervical sympathetic ganglia and T1-T5 sympathetic ganglia	Afferents travel with the afferents in the middle and inferior cervical sympathetic cardiac nerves and the thoracic sympathetic cardiac nerves and enter the cord from T1-T5	**BL 14;** T4	**CV 17;** T4
Heart	T1-T5, to upper thoracic and cervical sympathetic ganglia	All cervical sympathetic ganglia and T1-T5 sympathetic ganglia	Afferents travel with the afferents in the middle and inferior cervical sympathetic cardiac nerves and the thoracic sympathetic cardiac nerves and enter the cord from T1-T5	**BL 15;** T5	**CV 14;** T7
Liver	T5-T10, to superior thoracic (greater) splanchnic nerves and celiac plexus	Celiac ganglion	Afferents travel with the sympathetics and enter the cord from T5-T10	**BL 18;** T9	**LR 14;** T8, T9

Table 2-2 Sympathetic Input to the Back Shu and Front Mu Points, Continued

Gallbladder	T5-T10, to superior thoracic (greater) splanchnic nerves and celiac plexus	Celiac ganglion	Afferents travel with the sympathetics and enter the cord from T5-T10	**BL 19;** T10	**GB 24;** T9
Spleen (Pancreas)	T5-T11, to superior thoracic (greater) splanchnic nerves and celiac plexus	Celiac ganglion	Afferents travel with the sympathetics and enter the cord from T5-T11	**BL 20;** T11	**LR 13;** T10, T11
Stomach and Duodenum	T5-T11, to superior (greater) and middle (lesser) thoracic splanchnic nerves and celiac plexus	Celiac ganglion	Afferents travel with the sympathetics and enter the cord from T5-T11	**BL 21;** T12	**ST 25;** T10
Triple Heater (adrenal)	T7-L2, to superior (greater), middle (lesser), and inferior (least) thoracic splanchnic nerves and the first +/- second lumbar splanchnic nerves	Chromaffin cells of adrenal medulla	None reported	**BL 22;** L1	**CV 5;** T11, T12
Kidney	T10-L2, to middle (lesser) and inferior (least) thoracic splanchnic nerves and the first +/- second lumbar splanchnic nerves → celiac and renal plexuses	Celiac and aorticorenal ganglia	Afferents travel with the sympathetics and enter the cord from T10 to L2	**BL 23;** L2	**GB 25;** T12
Large Intestine	• **Cecum and appendix:** T10-T12 (cecum, appendix) to the superior (greater) and middle (lesser) thoracic splanchnic nerves → celiac and superior mesenteric plexuses • **Colon to the splenic flexure:** T10-L1 to the middle (lesser) and inferior (least) thoracic and first lumbar splanchnic nerves • **Splenic flexure to the rectum:** L1-2 through to the S2-S4 sacral chain ganglia, to the lumbar and sacral splanchnic nerves → inferior mesenteric and inferior hypogastric pelvic plexuses, to the	Superior and inferior mesenteric ganglia and ganglia in superior and inferior hypogastric plexuses	• **Cecum and appendix:** Afferents travel with the sympathetics and enter the cord from T10 to T12 • **Colon to the splenic flexure:** Afferents travel with the sympathetics, course through the superior and inferior mesenteric plexuses and splanchnic nerves, and into the cord from T10 to L1 • **Splenic flexure to the rectum:** Travel with the parasympathetic nerves and the pudendal nerves, into the cord at S2-S4	**BL 25;** L4 (receives sympathetic supply from T10-L2)	**ST 25;** T10
Small Intestine	T8-12 right, T8-T11 left, to the superior (greater) and middle (lesser) thoracic splanchnic nerves to the celiac plexus	Celiac and superior mesenteric ganglia	Travel with the sympathetics through the celiac and inferior mesenteric plexuses, into the cord from T8-T11	**BL 27;** (receives sympathetic supply from T10-L2)	**CV 4;** T12
Bladder	T11-L2 to the middle (lesser) and inferior (least) thoracic splanchnic nerves	Inferior mesenteric ganglion and sacral paravertebral ganglia	Travel with the parasympathetic nerves and some sympathetic afferents, to enter the cord at S2-S4 and L1-L2	**BL 28;** S2 (receives sympathetic supply from T10-L2)	**CV 3;** L1

*The afferent pathways listed in this table only pertain to the nociceptive avenues. Afferent fibers carrying other sensory information exist but have not been included here.

**Note: Sympathetic input to each spinal level is generally multi-segmental. That is, the tissues located in the vicinity of the Back Shu points along the inner line of the Bladder channel likely receive sympathetic supply from a spinal segment above and below that noted in the table.

Shu and Front Mu points in order to indirectly assess the function of the related organs. The point-organ relationships in the Shu-Mu system are arranged in a topographical fashion, with more cranial organs such as the lung and heart relating to more upper thoracic Shu-Mu point pairs, and more caudal organs such as the urinary bladder and large intestine showing up in the caudal point pairs. (See Table 2-2.)

Shu-Mu palpation should assess tension and tenderness in the muscles beneath the point, rather than merely the skin or subcutaneous tissue. Pain referred from an irritated viscus begins in deep somatic structures.[138] However, trophic changes in the skin follow visceral disturbances, as evidenced by thickened subcutaneous tissue and atrophic skeletal muscle.[139] When both members of the Shu-Mu pair demonstrate tenderness to palpation, assessment of that organ system would be prudent, since this may suggest visceral, rather than predominantly somatic dysfunction.[140,141,142,143,144]

Upon finding tender Shu-Mu points, an acupuncturist typically treats them, with the goal of reducing spinal cord windup and associated organ dysfunction. Mild, non-painful stimulation such as that provided by acupuncture may reduce pain and sympathetic hyperactivity in regions supplied by similar metameric/neuromeric/segmental fields.[145]

Table 2-2 also shows which spinal segments feed supply structures associated with the Back Shu and Front Mu points, the sites of synapse of pre- and post-ganglionic sympathetic neurons, and the course of nociceptive afferent pathways back to the CNS.

Table 2-3 provides the associated anatomy of organs outside of the Back Shu-Front Mu system. Relevant acupuncture points that could influence these organs can be determined on the basis of the neural structures linking the body surface (i.e., the soma) to these viscera.

Areas of referred tenderness precipitated by ongoing visceral nociceptive input land in metamerically connected cutaneous, subcutaneous, and muscular tissues. Metameric regions arise from similar segments of the developing embryo; referred pain and tenderness ordinarily occur ipsilateral to the disturbed structure.[146]

In the early stages of visceral disease, referred pain often has a deep, vague, and poorly localized quality. Pain at this phase (minutes to hours after the initial insult) feels like a dull discomfort, nearly always along the midline of the thorax or abdomen.[147] Autonomic concomitants such as sweating, nausea, vomiting, pallor, and a sense of impending death, may accompany true visceral pain in its early stages.[148]

If nociceptive signals continue from an irritated viscus, pain migrates to the body wall in the thorax or abdomen, usually located within similar or nearby spinal segments.[149] The referred pain begins to resemble somatic pain in that it becomes sharper, better defined, and well localized. Receptive fields expand in size in proportion to the number of painful episodes.[150] Over time, central sensitization as well as concurrent problems in other organs may cause pain to refer to adjacent myotomes, at which point neighboring Shu and Mu points could become tender.[151,152]

This is why, although the Back Shu and Front Mu pairs conventionally associate with only one organ, in reality, widespread multisegmental communication occurs. This limits the specificity of organs and acupuncture point relationships. Each paravertebral sympathetic ganglion may supply as many as six ipsilateral dermatomal levels.[153] Less predictable myotomal and scleromal innervation patterns further complicate interpretations of internal organ distress derived by myofascial palpation.[154]

While the nerve supply of the Back Shu-Front Mu points is elaborate and extensive, the general cranial to caudal layout of the Back Shu-Front Mu points exhibits a similar trend across species, even if specific vertebral levels differ. An alternative and probably more realistic arrangement would consist of over overlapping zones assigned to various organs instead of discrete points, as suggested for the horse.[155] Initially, this variance from the human norm arose to address difference in vertebral formulae between humans and other animals. As humans have twelve thoracic and five lumbar vertebrae and horses have eighteen thoracic and commonly six lumbar vertebrae, difficulties arise if one attempts to transpose the Back Shu points directly from the human to the horse.[156] Instead, Panzer proposes multi-level "association segments" rather than discrete association points.

Extrasegmental Acupuncture Points and Autonomic Function

Acupuncture points outside of the Back Shu-Front Mu system also modulate autonomic function, but do so through a variety of connections. Table 2-4 lists the associations between sympathetic structures and acupuncture points on the neck and trunk. Table 2-5 links points on the head and trunk with parasympathetic projections. Bear in mind that these are only partial lists, designed to denote the more common pathways utilized in a diverse and busy acupuncture practice.

The Brainstem's "Grand Central Stations" for Autonomic Reflexes in Neuromodulation: The Nucleus Tractus Solitarius and Rostral Ventral Lateral Medulla

Scientific research over the past decade has answered the question about how a point on the leg, ST 36, can treat both diarrhea and constipation. Instead of influencing autonomic activity in a unilateral direction, appropriately selected and stimulated acupuncture points modulate, or coax, bodily processes toward a homeostatic function.

Neuroscience has thus removed the need to rely on abstract "Yin-Yang balance" conceptualization by substituting metaphors with precise neurophysiologic descriptions that outline the trajectory from point to brain and spinal cord, and then on to the organ.

For example, two points on the limbs, ST 36 and PC 6, affect

Table 2-3
Anatomic Relationships of Organs Outside of the Shu Mu System[165]

Organ	Sympathetic Preganglionic Levels[166,167,168,169]	Site of Synapse of Pre- and Post-Ganglionic Sympathetic Neurons[170]	Course of Nociceptive Afferent Pathways into the Central Nervous System*[171]
Meninges and arteries of the brain	T1-T3 to and through the cervical sympathetic ganglia	T2-T6 sympathetic ganglia	Cranial nerves V, IX, and X enter the spinal trigeminal nucleus; afferents traveling through C1-C3 spinal nerves enter at the C1-C3 spinal cord segments
Eyes	T1-T4, to and through the cervical sympathetic ganglia	All cervical sympathetic ganglia and T1-T5 sympathetic ganglia	Ophthalmic branch of CN V enters the spinal trigeminal nucleus
Lacrimal gland	T1, T2, to and through the cervical sympathetic ganglia	All cervical sympathetic ganglia and T1-T5 sympathetic ganglia	Lacrimal nerve to the ophthalmic branch of CN V, to the spinal trigeminal nucleus
Parotid	T1, T2, to and through the cervical sympathetic ganglia	Celiac ganglion	Parotid nerve to the auriculotemporal nerve of CN V_3, to the spinal trigeminal nucleus
Submandibular, and sublingual glands	T1, T2, to and through the cervical sympathetic ganglia	Celiac ganglion	Submandibular branch of the lingual nerve to CN V_3, to the spinal trigeminal nucleus
Thyroid gland	T1, T2, to and through the cervical sympathetic ganglia	Celiac ganglion	Travel with sympathetic nerves to T1-2 spinal cord segments
Blood vessels of the skin and somatic structures of the head and neck	T1-T4, to and through the cervical sympathetic ganglia	Celiac ganglion	Some travel with sympathetic nerves to the T1-T4 spinal cord segments; others accompany CN V, CN IX, and CN X to the spinal trigeminal nucleus
Larynx	T1, T2, to and through the cervical sympathetic ganglia	Chromaffin cells of adrenal medulla	Superior laryngeal nerve to the spinal trigeminal nucleus
Esophagus	• **Cervical:** T2-T4, to and through the upper thoracic sympathetic paravertebral ganglia • **Thoracic:** T3-T6, to and through the upper thoracic sympathetic paravertebral ganglia • **Abdominal:** T5-T8, to the thoracic sympathetic paravertebral ganglia and superior thoracic splanchnic nerve	Celiac and aorticorenal ganglia	• **Cervical:** Some travel with the vagus to the NTS, others travel with the sympathetics to spinal cord segments T2-T4 • **Thoracic:** Some travel with the vagus to the NTS, others travel with the sympathetics to spinal cord segments T3-T6 • **Abdominal:** Some travel with the vagus to the NTS, others travel with the sympathetics to spinal cord segments T5-T8
Thoracic Aorta	T1-T5, to the thoracic sympathetic paravertebral ganglia	Superior and inferior mesenteric ganglia and ganglia in superior and inferior hypogastric plexuses	Travel with the sympathetic afferent pathways to the spinal cord levels T1-T6
Abdominal Aorta	T5-L2, through splanchnic nerves and direct branches	Celiac and superior mesenteric ganglia	Travel with the sympathetic afferent pathways to the spinal cord levels T5-L2
Ureters	• **Upper 2/3:** T10-L2, to the middle and inferior splanchnic and upper two lumbar splanchnic nerves • **Lower 1/3:** T11-L2, to the S2-S4 sacral ganglia	Inferior mesenteric ganglion and sacral paravertebral ganglia	• **Upper 2/3:** Travel with sympathetics to the spinal cord levels T10-L2 • **Lower 1/3:** Travel with sympathetic and parasympathetic nerves to enter the cord between T10 and T12
Uterus	T6-L2, to the splanchnic nerves to aortic and ovarian plexuses and superior and inferior hypogastric plexuses		Travel with the sympathetic afferent pathways to the spinal cord levels T11-L2
Testes, ductus deferens, epididymis, seminal vesicles, and prostate	T10-L1 through thoracic and upper lumbar splanchnic nerves, the celiac, aortic (intermesenteric), and superior hypogastric plexus, and hypogastric nerves to the inferior hypogastric (i.e., pelvic) plexus	Prevertebral ganglia and inferior mesenteric ganglion	Afferents through the testes (or ovaries) travel to T10. Parasympathetic afferents from these structures enter the S2-S4 portion of the spinal cord

*The afferent pathways listed in this table only pertain to the nociceptive avenues. Afferent fibers carrying other sensory information exist but have not been included here.

Table 2-4
Linkage of Autonomic Structures and Acupuncture Points -- Sympathetics[175,176]

Associated Spinal cord segments (C8-L3)	Structures Near Acupuncture Points and their Function	Acupuncture Points
C8-T5	**Superior cervical ganglion:** Supplies the head, neck, and heart; postganglionic axons "hitchhike" on the carotid arteries and branches to reach their destinations, which include the blood vessels supplying the lacrimal, salivary, and nasopharyngeal glands, the eye and dilator pupillae muscle, and remaining tissues.	SI 17
T1-T6	**Middle cervical ganglion:** Supplies the neck and heart (via the cardiac pulmonary plexus)	ST 10 GV 14[177]
T1-T7	**Inferior cervical ganglion (may fuse with the T1 ganglion to form the stellate ganglion):** Supplies the heart, caudal neck, arm, and posterior region of the head	ST 11
T1-T12	**Thoracic sympathetic ganglia (paravertebral and prevertebral)** • T2-T5 supply the heart and lungs • T5-T9 form the supply the stomach and proximal gut (fibers synapse in the celiac ganglion) • T8 to L2 supply the adrenal gland • T7 to L1 supply the superior mesenteric ganglion • T9-T11 supply the superior mesenteric ganglion • T9-T10 supply the inferior mesenteric ganglion • T12 supplies the renal ganglion • T12 fibers may also synapse in the aorticorenal ganglion (the combined superior mesenteric, renal, and inferior mesenteric ganglia) which supplies the kidney	GV or BL points at related spinal levels[178]
L1-L5	**Lumbar Sympathetic Ganglia** Axons from all lumbar ganglia region spinal nerves supplying the abdominal wall and pelvic limbs. Axons from most lumbar ganglia also join the abdominal plexuses. Fibers from lower lumbar sympathetic nerves migrate along the iliac arteries and branches to innervate pelvic vessels.	
S1-S4	**Sacral Sympathetic Ganglia** The pelvic sympathetic chains fuse in the midline, anterior to the coccyx, to form the ganglion impar. Postganglionic branches supply the wall of the pelvis and the pelvic limbs. Branches destined for the distal colon or pelvic viscera form the superior and inferior hypogastric plexuses. The superior hypogastric plexus lies below the origin of the common iliac arteries. The inferior hypogastric plexus is also called the pelvic plexus, and is located deep within the pelvis, close to the pelvic nerves.	S1: BL 31; BL 27 S2: BL 32; BL 28 S3: BL 33; BL 29 S4: BL 34; BL 30

Table 2-5
Linkage of Autonomic Structures and Acupuncture Points -- Parasympathetics[179,180]

	Parasympathetic Structures Near Acupuncture Points and their Function	Points
Cranial Parasympathetic Nerves	**Ciliary ganglion, CN III** Pupillary constriction.	ST 1 for CN III
	Sphenopalatine/pterygopalatine ganglion, lacrimal gland, CN VII Sends secretomotor signals to the lacrimal gland to stimulate tear production. Innervates the mucosal glands of the nose and mouth.	TH 23; GB 1
	Submandibular ganglion, submandibular and sublingual glands, CN VII Causes the submandibular and sublingual salivary glands to secrete saliva.	ST 5 for submandibular ganglion
	Otic ganglion, parotid gland, CN IX Causes the parotid gland to secrete saliva.	ST 7 for otic ganglion
	Carotid sinus nerve, CN IX Supply the carotid sinus and body	CV 23 ST 9 for carotid sinus
	CN X Vagal input to the thoracic and abdominal viscera	TH 17; SI 16; ST 9 CV 22; ST 9 for recurrent laryngeal nerve
Sacral Parasympathetic Nerves	**Sacral Nerves (S2-S4)** Supply the lower gut and the pelvic viscera. Modulate smooth muscle activity and stimulate pelvic glands to secrete	S2: BL 28, BL 32 S3: BL 29, BL 33 S4: BL 30, BL 34

brainstem nuclei[172,173,174] that participate in long-loop reflexes between the acupuncture point and internal organs. These nuclei, most notably the nucleus tractus solitarius (NTS) and its partner, the dorsal motor nucleus of the vagus (DMNV) as well as the rostral ventral lateral medulla (rVLM), modulate autonomic tone based on somatoautonomic input converging on the NTS and rVLM.[24,25,26]

The Nucleus Tractus Solitarius

The NTS interconnects numerous central nervous system networks. It acts as an important relay center for sensory afferents from diverse sources. Afferent signals arising from peripheral chemoreceptors, baroreceptors, the gastrointestinal tract, cardiovascular system, lungs, and the airways terminate in the NTS.[27] Some of these afferents reach the NTS by hitchhiking on cranial nerves III, VII, IX, and X, i.e., the cranial nerves that carry parasympathetic fibers.[28]

The NTS also receives input from afferents innervating the skin, subcutaneous tissues, and muscle in an ongoing fashion. Adding somatic afferent stimulation through acupuncture augments or otherwise modifies this input.[286]

For example, acupuncture points on the face (supplied by the trigeminal nerve) and limbs (such as ST 36, supplied by the fibular (peroneal) nerve), influence gastrointestinal motility, blood pressure, cardiopulmonary function, and pain. In one study, researchers used the cellular marker of neural activity, c-fos, to identify activated neurons in the CNS after gastric distension and electroacupuncture. They stimulated points on the face (GB 14, ST 2, and ST 6). Their results showed that both noxious visceral information and non-noxious somatic afferent stimulation (i.e., acupuncture) converged in the NTS. This suggested that the NTS mediates EA analgesia through neuromodulation.[29,287]

Receptors from the cardiovascular and respiratory systems also send messages into the NTS. Baro- and chemoreceptors living in the bifurcation of the carotid artery help the body autoregulate blood pressure and blood chemistry.[30] Impulses from the carotid body and sinus artery travel to the NTS by way of the glossopharyngeal nerve (CN IX). There, they converge with input from the reticular formation and the hypothalamus as well. The NTS assembles this information and determines the appropriate reflex autonomic responses.[31]

Impaired sensing capability from dysfunctional baro- and chemoreceptors triggers sympathetic bias that could conceivably lead to myocardial infarction, heart failure, and stroke.[32] Carotid body and carotid sinus electromodulation may help prevent or treat cerebrovascular events by restoring autoregulation.[33] The idea of externally influencing the carotid sinus is not new; carotid sinus massage has been used to determine the cause of syncope and also to terminate supraventricular tachycardia through alterations in autonomic tone.[34,35] The acupuncture point ST 9 (located near the carotid body and sinus) has long received attention as a point that is valuable for treating “shortness of breath”, “asthma”, “sudden turmoil disorder”, “pulseless syndrome”, “hypertension”, and “hypotension”.[36] This indicates that the ancient Chinese recognized the role of structures stimulated by needling ST 9 in cardiopulmonary problems, even though they were unaware of the actual neurophysiological mechanisms involved.

Far and away, the largest body of research exploring the impact of acupuncture on NTS has focused on its role in restoring normal gastrointestinal motility.[288] This results from communication with its neighbor, the dorsal motor nucleus of the vagus (DMNV). Together, the NTS (a site that receives afferent information) and the DMNV (an efferent structure) form the dorsal vagal complex, or DVC. The DVC thus comprises sensory and motor aspects, creating a conduit for somatovagal and vagovagal reflexes.[49] In this manner, the DVC is a parasympathetic preganglionic center that modifies visceral output based on convergent, somatoautonomic input.

The Rostral Ventral Lateral Medulla

The rostral ventral lateral medulla (rVLM), like the NTS, receives convergent input from both visceral and somatic sources. The rVLM also assists the NTS in the baroreceptor reflex.[37] The rVLM affords the main source of tonic excitatory input to cardiovascular sympathetic preganglionic neurons in the spinal cord.[38] It modulates cardiovascular responses according to the signals it receives from the gut and soma. The neurotransmitters nitric oxide, opioids, and nociceptin are a few examples of the chemicals involved in its activity.[39,40,41,42]

EA influences cardiovascular function at least in part by affecting rVLM activity.[43,44,45] Physiologic investigations demonstrate point- (i.e., nerve-) specific cardiovascular responses in the rVLM.[46] EA at points associated with deep nerves (such as the median (PC 5, PC 6) or deep radial (LI 10, LI 11)) produce stronger and longer-lasting modulation of visceral reflex pressor responses than does EA over superficial cutaneous nerves, such as at the terminal branches of the tibial nerve (KI 1, BL 67).[47] Cardiovascular responses to EA also demonstrate frequency specificity. Research shows that both EA at 2 Hz and MA (dry needling) inhibit reflexive excitatory cardiovascular responses caused by visceral afferent stimulation, but EA at 40 Hz or 100 Hz does not.[48]

The rVLM influences gastrointestinal motor function, too. Compared to somatic afferent stimulation at ST 36, which, after reaching the NTS, increases gastric contractions (a parasympathetic effect), stimulation at ST 25 predominantly influences the rVLM, resulting in gastric relaxation (a sympathetic effect).[289]

Somato-somatic Reflexes

Each acupuncture point delivers a panoply of effects. Some influence both somatic and autonomic function simultaneously. ST 36, for instance, treats not only constipation and diarrhea through the mechanisms just described, but also helps alleviate back pain and pelvic limb dysfunction.

MA at ST 36 activates afferent fibers belonging to groups I, II, III, and IV.[196] Group II and III afferents elicit acupuncture analgesia; afferents belonging to groups II, III, and IV also impact various autonomic processes,[197,198] while activation of Group I afferents more clearly influence motor neuron activity.[199] All of these afferents connect to the fibular nerve, supplied by lumbosacral spinal cord segments. Patients with disk disease or back pain in the low back may derive relief from ST 36 stimulation at least in part because of the spinal segmental analgesia it provides. From a supraspinal perspective, EA at ST 36 regulates beta-endorphin and adrenocorticotropic hormone (ACTH) levels in the hypothalamus and pituitary, bestowing generalized analgesia and anti-inflammatory effects.[201,202,290]

EA at ST 36 also affects structures in the limbic system, i.e., brain structures involved in processing pain, memory of pain, and its emotional qualities.[291,292] Furthermore, ST 36 neuromodulation leads to changes in cerebral blood flow in the frontal lobes, brainstem, and thalami. These alterations occur as a consequence of acupuncture treatment and relate to pain-relief.[200] Thus, even considering this one point's effects, one sees how acupuncture alleviates pain through a multiplicity of mechanisms.[192,193,194]

While needling points such as ST 36 can help patients with conditions such as back pain through generalized analgesic mechanims, direct treatment of painful regions is usually also necessary for successful treatment. Palpation and postural evaluation of the back, neurologic testing, and mobility assessments all lend vital information about the specific problems plaguing the patient. The medical acupuncturist then considers ways in which to stimulate sites related to the myofascial and neuroanatomic matrix in order to optimize relief, especially when medication has failed to do so.[208,209]

This is where somato-somatic reflexes through acupuncture neuromodulation perform vital roles in prompting recovery. In the case of back pain, for example, stimulation of paravertebral somatic afferent fibers at acupuncture points along the spine suppresses activity in spinal nociceptive neurons.[195] This alleviates muscle tension, fascial restriction, and local nerve irritation and inflammation, ultimately reducing spinal cord facilitation. Reduction in facilitation (wind-up) helps dampen pain transmission, efferent motor activity and sympathetic tone, leading to analgesia, muscle relaxation, and improved circulation. Obtaining a twitch in the muscle through electrical stimulation, similar in ways to the needling of trigger points, provides significantly greater immediate and sustained relief of myofascial low back pain than stimulating only the muscle or overlying skin.[215]

As an illustration of how somato-somatic reflexes connect acupuncture points to painful sites, Table 2-6 lists groups of acupuncture points often used for spinal pain, their location, and the nerves they most intimately impact. Not included are peripheral points such as BL 40, BL 60, ST 36, SI 3, and others that provide additional analgesia, depending on the patient's pain problem(s). In general, it is standard practice to focus not only on the specific spinal segment or vertebral level involved in the pain problem, but also on points associated with spinal segments above and below. This takes into account the multisegmental somatic nerve supply to spinal structures as well as the discrepancy that appears between the vertebral level and dermatomal nerve supply in the caudal spine. One should not neglect the sympathetic contribution to the pain problem. Therefore, one should consider selecting points along paraspinal locations that provide autonomic input to the region.[244,245]

Table 2-6 Acupuncture Points Commonly used for Spinal Pain

Acupuncture Points (Medial to Lateral)	Location	Related Nerves[246]
Governor Vessel (GV) points and additional interspinous points along the midline	Between spinous processes of adjacent vertebrae, on the dorsal midline	Medial branch of the dorsal (posterior) primary ramus
Huatojiaji points[247,248,249,250]	0.5 cun lateral to the midline, from C1 to L5	Medial branch of the dorsal primary ramus
Facet joint points	1.0 cun lateral to the midline, from C1 to L5	Medial branch of the dorsal primary ramus
Inner Bladder line	1.5 cun lateral to the midline	Lateral branch of the dorsal primary ramus
Outer Bladder line	3.0 cun lateral to the midline	Ventral branch of the dorsal primary ramus
Myofascial Trigger points	Variable	Variable
Front Mu points (for organ relationship)	Variable	Variable

Table 2-7 associates structures often implicated in spinal pain such as intervertebral disks, facet joints, and spinal muscles.[251] Inflammation, compression, developmental anomalies, or degeneration of these tissues can all lead to spinal pain. The table includes mention of particular acupuncture point groupings that may most directly influence pain transmission in the affected nerves.

Controlled trials and systematic reviews in human research provide increasingly strong supportive evidence indicating that acupuncture effectively treats chronic spinal pain.[222,223,224,225,226,227,228,229,230,231] Several uncontrolled studies have reported that acupuncture also reduces spinal pain in dogs and horses.[232,233,234,235,236,237,238] According to Adrian R. White, MD, the author of several systematic reviews on acupuncture, “Acupuncture treatment should be considered for anyone who has nonspecific mechanical back pain that has persisted for 6 weeks or more despite standard treatment.”[239,240] In humans, ten sessions of acupuncture produced stable, long-term effects lasting at least six months according to a recently published prospective cohort study.[241] A 2005 paper systematically reviewing acupuncture for chronic low back pain echoed the findings of earlier work, concluding that adding acupuncture plus conventional treatment produced better analgesia and functional improvement than conventional treatments alone.[242,243] Acupuncture saves money; results from a 2011 study in Canada suggest that patients with low back pain were less likely to visit physicians if they had received acupuncture, thereby lowering costs spent on healthcare for these patients.[293]

Assembling Acupuncture Points to Impart a Meaningful Neuromodulatory Input

Whether treating back pain, irritable bowel syndrome, trigeminal neuralgia, or radiation-induced xerostomia, a medical acupuncturist can simplify the neural input protocol by asking three simple questions:

1. What is the problem and how is it expressing itself in the soma with myofascial dysfunction, pain, tenderness to palpation, etc.?
2. How did the problem affect neurophysiologic activities in the periphery, CNS, and ANS?
3. Which acupuncture points will influence these affected nerve pathways both specifically and comprehensively?

The physician acupuncturist will find the answers to question 1 when taking the patient’s history, performing the physical examination, and pursuing an appropriately detailed workup. The answers to questions 2 and 3 require a solid foundation in neuroanatomy, neurophysiology, and scientifically based medical acupuncture. Acupuncture point anatomy, such as that presented in the chapters that follow, informs the physician about the local, regional, and system-wide impact of stimulating each site.

Summary

Whether a clinical problem involves pain, visceral disturbance, or a psychological or somatic dysfunction, numerous neural networks participate in the problem. This is due to the widespread interactions between the nociceptive and autonomic systems not only in the periphery, but also in the spinal cord, brainstem, and several sites in the cerebrum and cerebellum.[280] Fortunately, acupuncture can influence many of these loci, including, most notably, the medulla, pons, periaqueductal gray, hypothalamus, amygdala, insular cortex, and anterior cingulate gyrus. These sites serve to regulate autonomic outflow, balance endocrine function, and blunt pain.[281] The key is knowing which nerves and regions to target. Hence, the fundamental premise of this book.

Table 2-7
Potential Sources of Back Pain, Their Innervations, and Related Acupuncture Points[252,253,254]

Structural Source of Back Pain	**Related Neural Elements**	**Acupuncture Points Influencing Nerves Related to the Pain Source – Select Points at One to Three Spinal Segments Above and Below the Lesion, as Well as Those Located at the Pertinent Level From Which Sympathetic Contributions Arise**
Intervertebral disc	The outer third of intervertebral disks contains nociceptors and mechanoreceptors. • The sinuvertebral nerve innervates the dorsal (posterior) aspect of lumbar intervertebral disks.[255] The sinuvertebral nerves consist of somatic and sympathetic fibers. When they return to the spine, they can ascend or descend for up to 5 segmental levels.[256,257] Sympathetic fibers supplying disc in the lumbar spine will arise from the thoracolumbar level. Low back pain caused by the sinuvertebral nerve is often diffuse because of its unique anatomic pathway and sympathetic components.[258] The dorsal portion of the lower lumbar disks receives innervation from sensory fibers arising from the T13 to L2 DRG's.[259] • Branches of the ventral rami and the gray rami communicantes supply the lateral aspects of the disks in the lumbar spine.[260,261] The lateral portion of the L5-L6 intervertebral disc (in rats) arise from both ipsilateral and contralateral dorsal root ganglion (DRG) neurons from the T13, L1, and L2 levels.[262] • The ventral (anterior) portion of the L5-L6 intervertebral disc (in rats) receives innervation from the L1 or L2 spinal nerves. This may explain why patients with lower lumbar disc problems may also experience pain in the inguinal region, which corresponds to the L1-L2 dermatome.[263,264,265] • "Paradiscal rami" from the rami communicantes cross intervertebral disks and course through the connective tissue of the disc deep to the origin of the psoas muscle. These rami also likely provide discal innervation.[266] • Severely degenerated lumbar intervertebral disks exhibit more extensive disc innervation than do normal disks.[267]	Huatojiaji points,[1] "facet joint points"[268]
Facet joint capsule	The joint capsule is richly innervated by proprioceptors and nociceptors. The synovial membrane of the lumbar facet joint (in rats) is supplied by sensory and sympathetic fibers.[269] The dorsal rami supply the lateral portions of the facet joints. The sinuvertebral nerves supply the medial portion of the facet joints. Facet joints in the low back receive both segmental and nonsegmental innervation, due to the innervation from sympathetic postganglionic neurons in the thoracolumbar region and the multisegmental nature of spinal innervation.[270] In rats, the L5/L6 facet joint receives multisegmental innervation from the L1 to L5 DRGs.[271]	Huatojiaji points, "facet joint points"[272]
Costovertebral joints (thoracic spine only)	Dorsal rami and sympathetic fibers supply the costovertebral joints.	Huatojiaji points, "facet joint points"
Dorsal root ganglion (DRG)	Mechanically sensitive nociceptors (i.e., mechanonociceptors) in the nervi nervorum of the epineuria surrounding the DRG may contribute to pain if compression or tension affects the DRG.	Points along the inner Bladder channel

Table 2-7 Potential Sources of Back Pain, Their Innervations, and Related Acupuncture Points, Continued

Spinal ligaments: **1) Longitudinal ligaments – dorsal/posterior and ventral/anterior** **2) Supraspinal ligaments** **3) Interspinous ligaments**	These ligaments contain free nerve endings that have been implicated as potential contributors to back pain. • The sinuvertebral nerve supplies the dorsal (or posterior) longitudinal ligament. • Recurrent branches of the rami communicantes innervate the ventral (or anterior) longitudinal ligament.[273] • The grey rami communicantes supply the anterior (ventral) longitudinal ligament. • Medial branches of the lumbar dorsal rami supply the interspinous ligaments	Points along the Governor Vessel channel
Vertebral periosteum	The periosteum contains an extensive plexus of nerve fibers that exhibits the lowest pain threshold of any of the deep tissues.	Huatojiaji points or points along the Governor Vessel channel
Meninges	The dura is sensitive to mechanical and noxious stimulation; meningeal irritation may contribute to back pain. The sinuvertebral nerve supplies the dura mater. The dura mater of the lower lumbar spine receives sensory fibers from the upper lumbar ganglia; these fibers may interact with sympathetic nerves and mediate pain in the low back.[274]	Points along the Bladder channel
Muscles attaching or referring to the back	Myofascial pain is characterized by palpable, taut bands occurring lengthwise along muscles that contain exquisitely tender regions. Lateral branches of the dorsal rami supply the iliocostalis lumborum muscle; intermediate branches of the lumbar dorsal rami supply the longissimus muscle. Medial branches of the lumbar dorsal rami supply the multifidus and the short intersegmental muscles (intertransversarii mediales and interspinales).	Local, direct needling into the taut band or trigger point[275]
Thoracolumbar fascia	Cutaneous branches from dorsal rami of lumbar spinal nerves innervate the thoracolumbar fascia. The thoracolumbar fascia may be involved in a neurosensory capacity in controlling the lumbar spine mechanism.[276] Nerves supplying the thoracolumbar fascia in humans with chronic mechanical back pain may undergo degeneration secondary to ischemia or inflammation.[277]	Points along the Governor Vessel, Bladder, or Gallbladder channels, depending on the area affected by pain, as determined by palpation
Sacroiliac joint	Sensory innervation to the sacroiliac joint arises from neurons in the DRGs ipsilateral to the joint from L1 to S2; sensory fibers from the L1 and L2 DRG's course through the paravertebral sympathetic trunk.[278]	
Dysfunctional viscera causing or resulting from central sensitization[279]	Address both the myofascial and visceral components.	Points along the Governor Vessel, Bladder, or Gallbladder channels, depending on the area affected by pain, as determined by palpation

Section 2::

Acupuncture Points and Channels

Chapter 3:: Introducing the Points and Channels

The point tables that follow group acupuncture points according to channel. Although the organ-based naming system for the channels no longer makes sense (if it indeed ever did), it has been retained in order to remain consistent with the World Health Organization (WHO) Standardization of Acupuncture Nomenclature. While retaining this common terminology facilitates communication between those in teaching, research, and clinical practice, it causes confusion because few, if any, points on a given channel have any association with their namesake organ.

Designations of the alphanumeric names of acupuncture points may not include a space between the two-letter channel designation and the point number or, instead, a dash. All are acceptable. For example, the fifth point on the Lung channel may appear as LU 5, LU5, or LU-5. The style selected to denote points in this book utilizes a space between the channel abbreviation and point number.

The indications listed for each point in the chapters of this book provide a glimpse of potential clinical applications and neuroanatomically justifiable or evidentially supported combinations. When available, published trials or experimental evidence pertaining to that point are included. However, medical judgment regarding the appropriate interventions for each patient may necessitate treatment other than acupuncture. For example, although a classical application of LU 4 is chest pain and shortness of breath, patients experiencing these symptoms should receive emergency evaluation and treatment without delay.

The evidential support selected for each point, when available, includes case reports, case series, and uncontrolled trials, along with randomized controlled trials when available. More research, with treatment controls based on a neuroanatomic understanding of acupuncture instead of an energy basis, is certainly needed. Otherwise, research methodology suffers and studies lead to conflicting or confusing results. For example, belief in the energy-meridian concept may prompt a metaphor-based researcher to select verum and sham points too close together. When two points share innervation, one can expect to find non-significant differences between the treatment and control groups, leading skeptics to claim that the effects of acupuncture are essentially those of placebo.

Each point will have listed the alphanumeric code for the channel and individual point number, the Pinyin name of the point, and the English translation of the Pinyin point name. Instead of referring to the San Jiao or Triple Energizer channel by its Chinese name or English name, the term “Triple Heater” was chosen.

The order of channel presentation along with their abbreviations appear below:

Lung (LU)
Large Intestine (LI)
Stomach (ST)
Spleen (SP)
Heart (HT)
Small Intestine (SI)
Bladder (BL)
Kidney (KI)
Pericardium (PC)
Triple Heater (TH)
Gallbladder (GB)
Liver (LR)
Governor Vessel (GV)
Conception Vessel (CV)

Chapter 4:: Locating Points on the Body

Chapter Highlights

Safe acupuncture requires a solid grasp of anatomy.

Precision and consistency in point location is a precursor to clinically effective and predictable neuromodulation.

Inaccurate and variable point locations may produce to unexpected results in clinical and research settings.[1,2]

As important as precise, neuroanatomically accurate point location is, the two traditional methods of point location, i.e., proportional and directional systems, do not always lead to the same locus.[3,4] Instead, the emerging recommendation encourages acupuncturists to employ these techniques as rough estimates but to finalize site selection through touch.

Remember, too, that the targets for neuromodulation are not dots imagined on skin but neurovascular passageways, muscle components, or fascial elements. With experience, the ability to visualize layered anatomy during palpation expands as reliance on standard dictated measurements recedes.

One of the main problems pertains to the fact that acupuncture point location relies on a system of anthropometry designed for a monoethnic population from a distant era.[5] Even in Asia, the length and girth of today's patients' limbs and torsos reflect idiosyncrasies of life style, nutrition, adiposity, and genetics. Anthropometric assessments from millennia ago did not foresee or predict today's diverse populations. The mismatch becomes more extreme when one extrapolates the human points and channels onto other species.[6]

Both the proportional and directional methods of locating points utilize the Chinese anatomical inch called a "cun" (pronounced "tsun"); the plural form is also "cun".

Finding a point begins by defining the length of an anatomical segment as a certain number of cun.[7] Cun are relative to a patient's size, allowing for flexibility across individuals and throughout growth stages. For example, the cun count on the forearm remains twelve regardless of its actual length; from infancy to young adulthood and old age, the forearm remains 12 cun long. See Table 4-1 for a complete list of cun distances.

Proportional Method of Point Location

The proportional approach estimates point locations by dividing the distance between two reference points or topographical landmarks into equal-sized components based on conventionally accepted predetermined anthropometric values. For example, in order to locate TH 5, which can be found at roughly 2 cun proximal to the wrist on the dorsal surface, the proportional method would begin by subdividing the 12-cun antebrachium into six segments, each 2 cun long. The proportional method tells us that TH 5 lands between the distal two sixths, as illustrated in Figure 1.

Table 4-1 Cun distances employed for finding points according to the proportional method.[9]

Region	Cun Measurement Between the Following Landmarks	Cun count	Figure
Head/Neck	Right and left ST 8	9	5
	Middle of the eyebrow to the anterior hairline	3	6
	Anterior to posterior hairlines	12	6
	Posterior hairline to the inferior border of C7 spinous process (GV 14)	3	6
	Right and left mastoid processes	9	7
Trunk	Right and left ST 17 (at the nipple)	8	8
	Suprasternal notch (CV 22) to the xiphisternal synchondrosis (or xiphisternal joint) (CV 16)	9	9
	Xiphisternal synchondrosis (joint) (CV 16) to the umbilicus (CV 8)	8	10
	Umbilicus (CV 8) to the superior border of symphysis pubis (CV 2)	5	10
	Center of axilla (HT 1) to the tip of the 11th rib (LR 13)	12	11
	Medial border of the scapula to the posterior midline	3	12
	Inferior border of spinous process of T1 (GV 13) to the tip of the coccyx	30	13
Arm	Superior end of the anterior axillary crease to the cubital crease	9	14
	Cubital crease to the distal wrist crease	12	15
Leg	Superior border of symphysis pubis (CV 2) to the superior tip of the patella	18	16
	Lateral prominence of the greater trochanter to the popliteal crease	19	16
	Popliteal crease to the lateral malleolus	16	17
	Medial tibial condyle to the medial malleolus	13	17
	Gluteal fold (BL 36) to the middle of the popliteal crease (BL 40)	14	18

Directional Method of Point Location

The directional method employs a side-by-side line-up of cun, meted out as thumb widths that each measure out 1 cun. Other digit-based measurements can provide “shorthand” cun counts, as shown below. This approach requires calibration of the practitioner’s hands against the patient’s; it is the patient’s hand size that determines the cun width, but the acupuncturist’s hand finds the points. Therefore, before beginning a treatment, it is common for the practitioner to match her or his hand size against the patient’s. If the two measure about the same, then no adjustments are required. On the other hand, if the practitioner’s hand dimensions differ from the patient’s, one needs a “fudge factor” when measuring cun. Patient adiposity can also complicate cun measurement with the direct method.[8]

Cun “Shorthand”

- 1 cun = the width of the thumb at the interphalangeal joint (Figure 2) or the distance between the proximal and distal interphalangeal joints of the middle finger (Figure 3).
- 1 cun = the width of the apposed index and middle finger measured at the level of the interphalangeal joint of the index finger (Figure 4).
- 3 cun = the width of all four fingers measured at the level of the proximal interphalangeal joint of the index finger (Figure 4).

Summary

As they say in the real estate business, “Location, location, location.” For acupuncture, we might add, “Anatomy, anatomy, anatomy.”

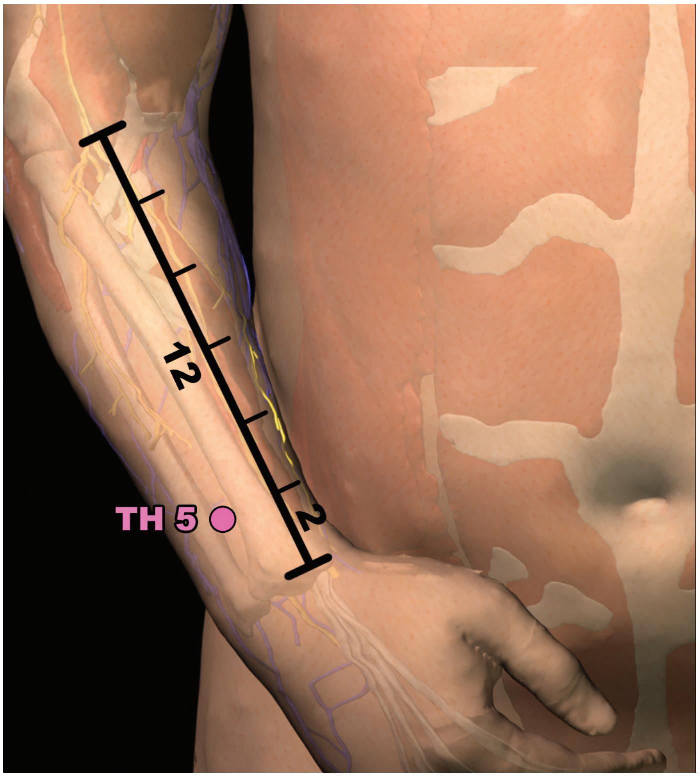

Figure 1. The **proportional method** approximates cun distances by divvying up parts of the body into separate sections and then specifying the relative position of a point in terms of those sections. For example, TH 5, shown in this image, lands 2 cun proximal to the dorsal wrist crease. The cun measurement for the antebrachium equals 12. Therefore, TH 5 falls between the last two sixths, 10 cun distal to the elbow or 2 cun proximal to the wrist. In practice, in order to determine the length of each of the six segments, one first divides the antebrachium into halves and then subdivides each half into thirds, yielding six equal portions. Contrast this method with the **directional approach**, which utilizes the distance of two of the patient’s thumb widths from the dorsal wrist crease. The examiner should arrive at roughly the same region with both methods. However, final point selection should result from palpation for a depression, a report of tenderness from the patient, and/or specification of the exact site for stimulation. In the case of TH 5, this may include the extensor digitorum or extensor digiti minimi tendon, the extensor indicis or extensor pollicis longus muscle, the posterior interosseous nerve, or one of the other structures in the vicinity.

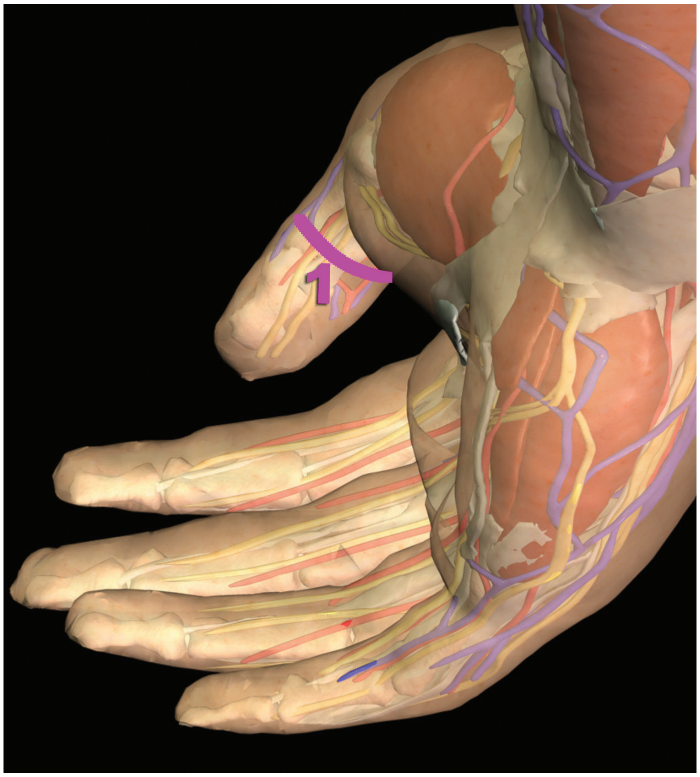

Figure 2. The width of the thumb at the inter-phalangeal joint equals 1 cun.

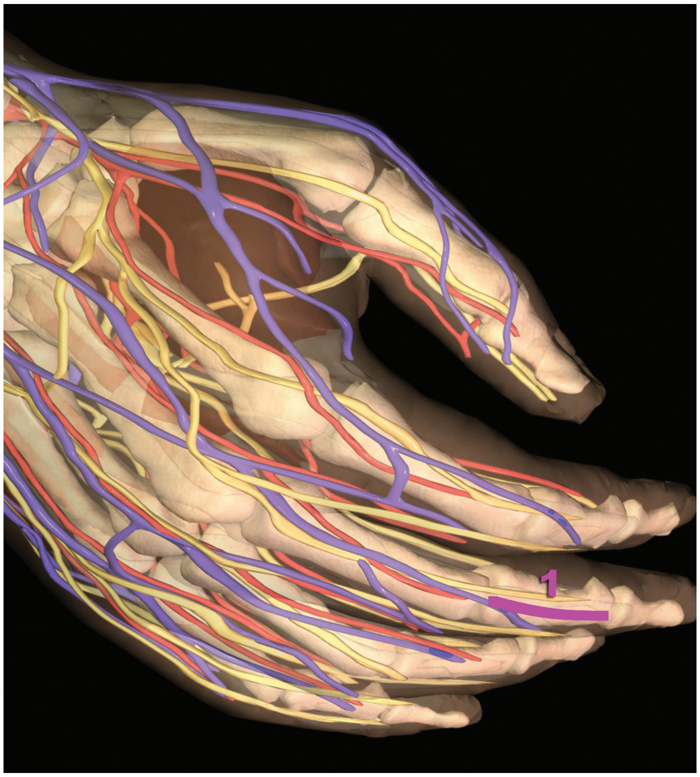

Figure 3. In addition to the thumb width, one can utilize the length of the middle phalanx on the third finger to measure a cun.

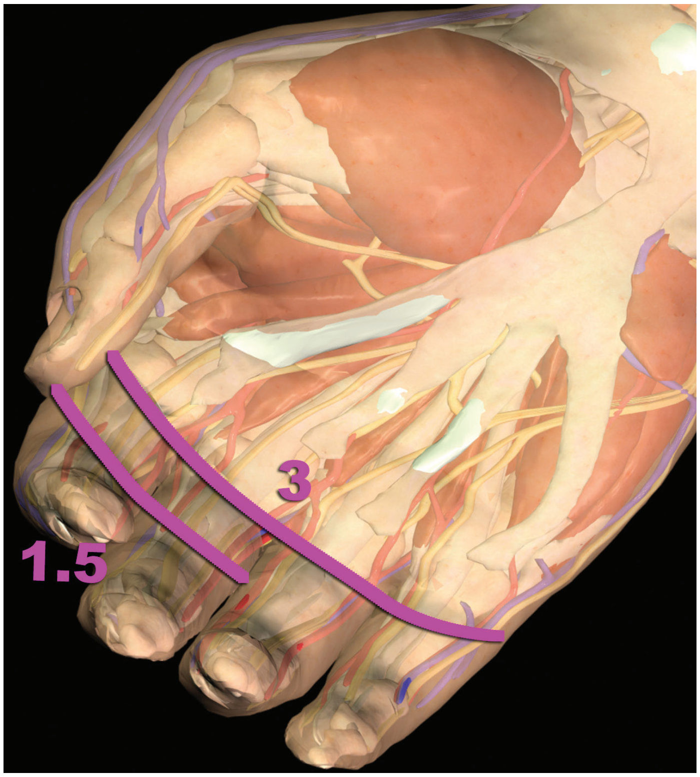

Figure 4. The patient's index and middle fingers held closely together measure 1.5 cun. The width of all four fingers held together counts as 3 cun at the level of the proximal interphalangeal joints.

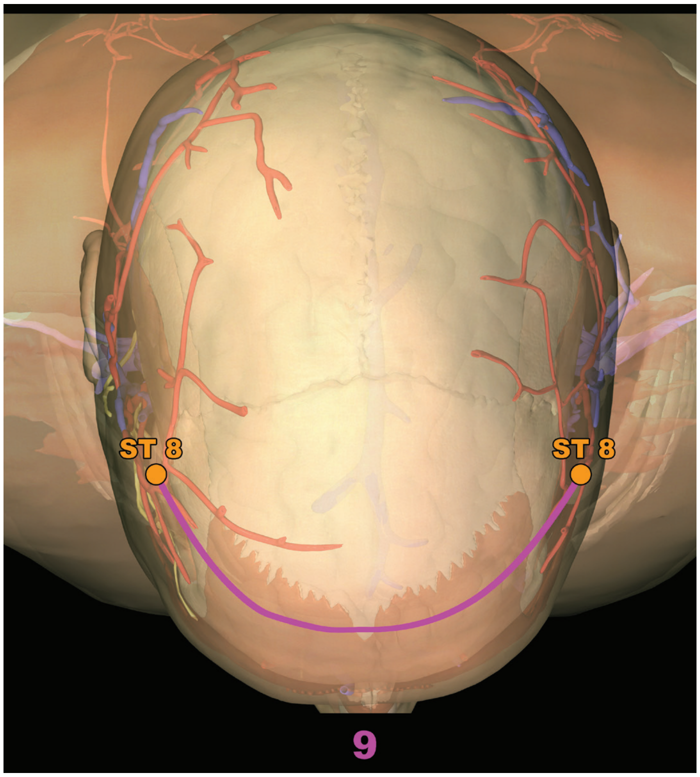

Figure 5. The distance from the right ST 8 to the left equals 9 cun.

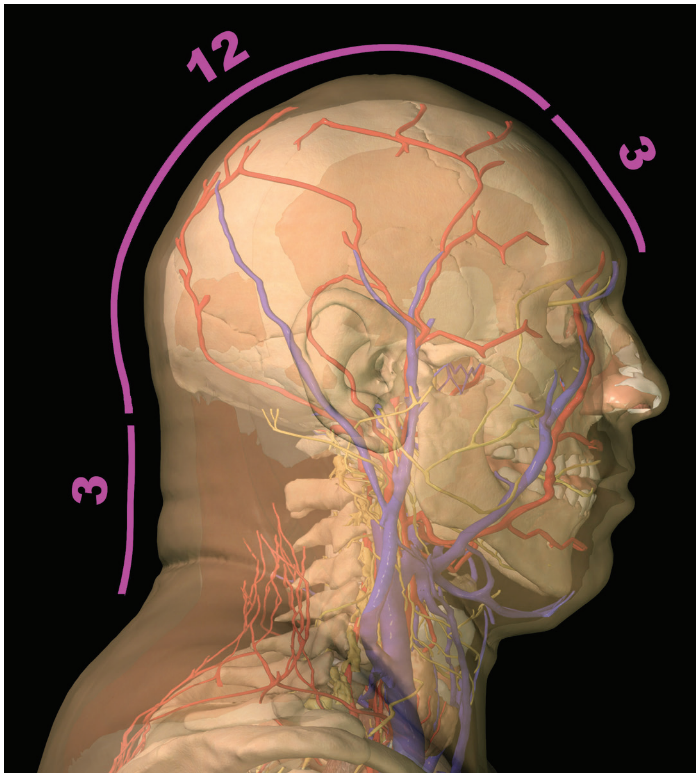

Figure 6. Along the sagittal plane, the distance from glabella to the anterior hairline measures 3 cun. There are 12 cun between the anteior and posterior hairlines and 3 cun from the posterior hairline to the inferior border of C7.

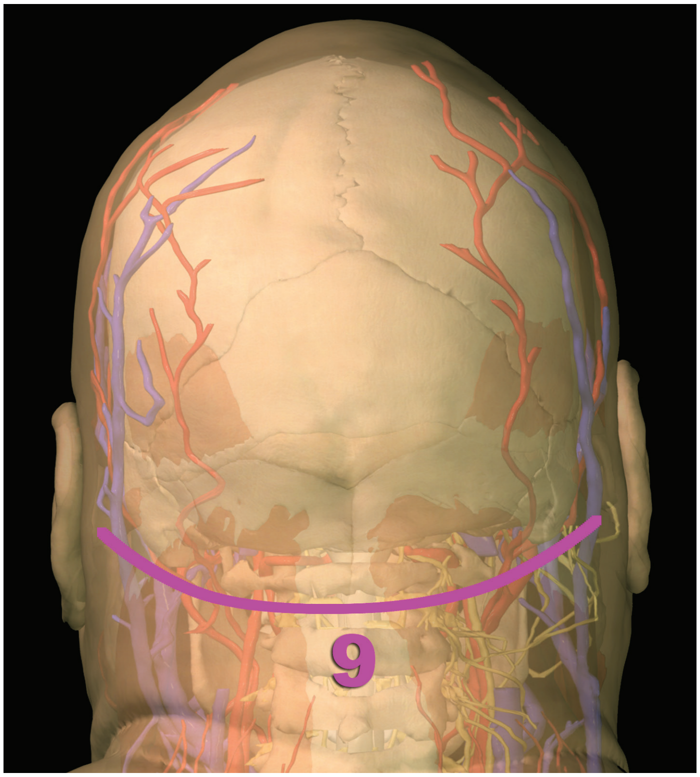

Figure 7. The distance between the right and left mastoid processes approximates 9 cun.

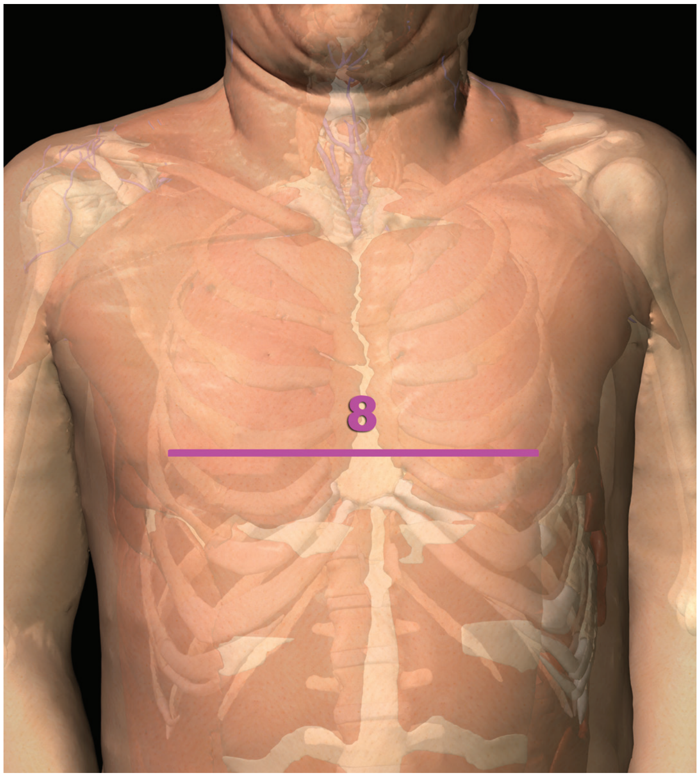

Figure 8. The distance between the two nipples equals 8 cun.

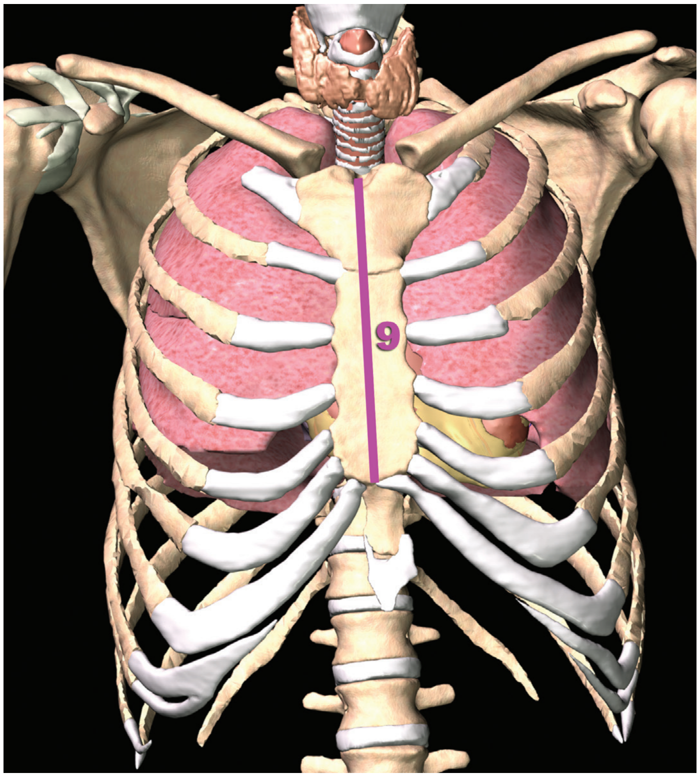

Figure 9. The suprasternal notch to the xiphisternal synchondrosis measures 9 cun.

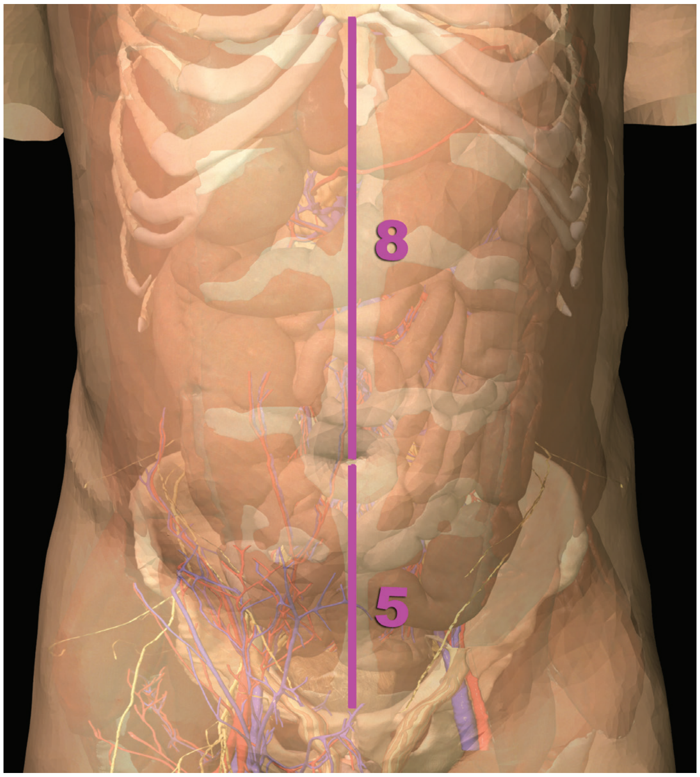

Figure 10. The absence of bony landmarks over the abdomen encourages more reliance on the proportional method of point location when demarcating the location of points on the anterior torso. The distance from the xiphisternal synchondrosis to the umbilicus is 8 cun, but it is only 5 cun from umbilicus to the superior border of the symphysis pubis.

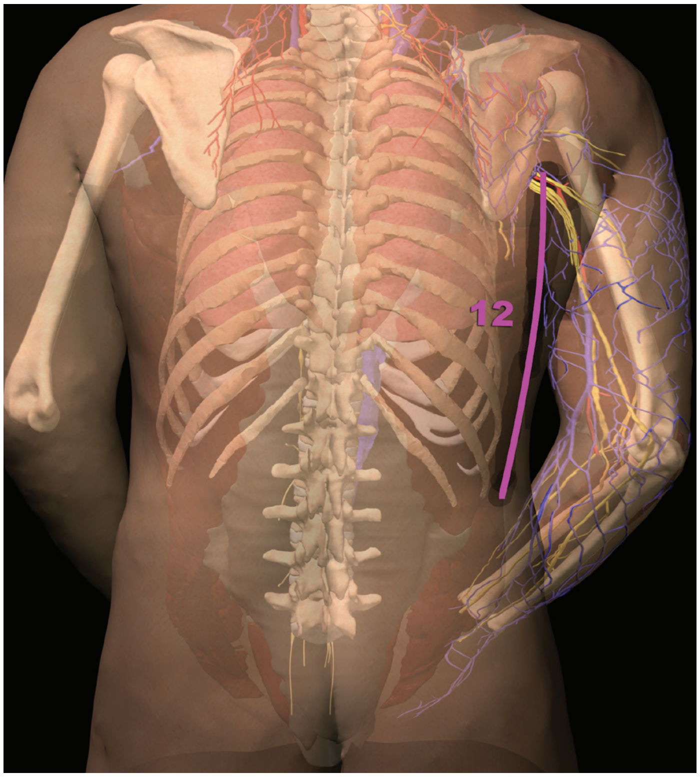

Figure 11. 12 cun cover the distance between the center of the axilla and the tip of the 11th rib.

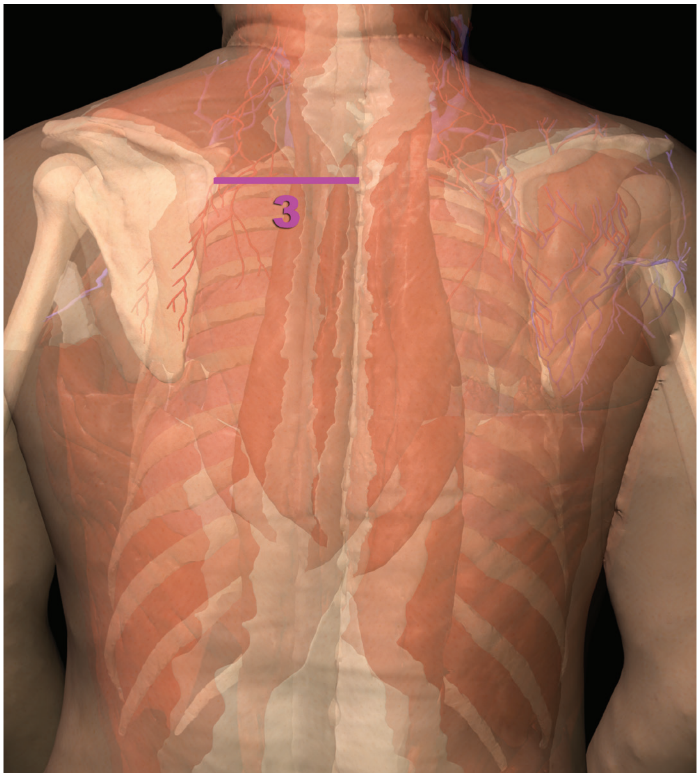

Figure 12. The distance between the medial border of the scapula and the midline is often given as 3 cun. However, the spatial relationship of the scapula and the spine depends on the position of the scapula.

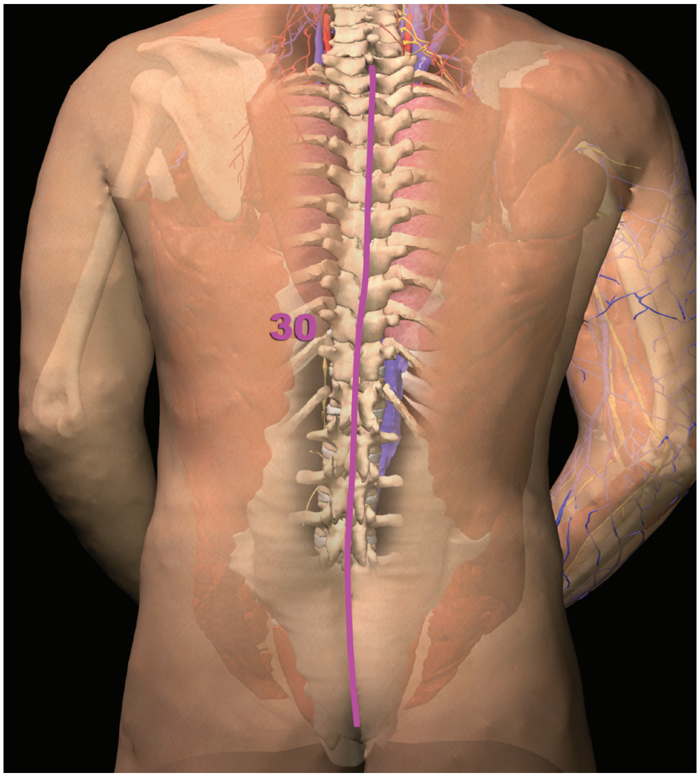

Figure 13. The length of the spine from T1 to the tip of the coccyx equals 30 cun. Note that this individual is missing the 1st rib on the right.

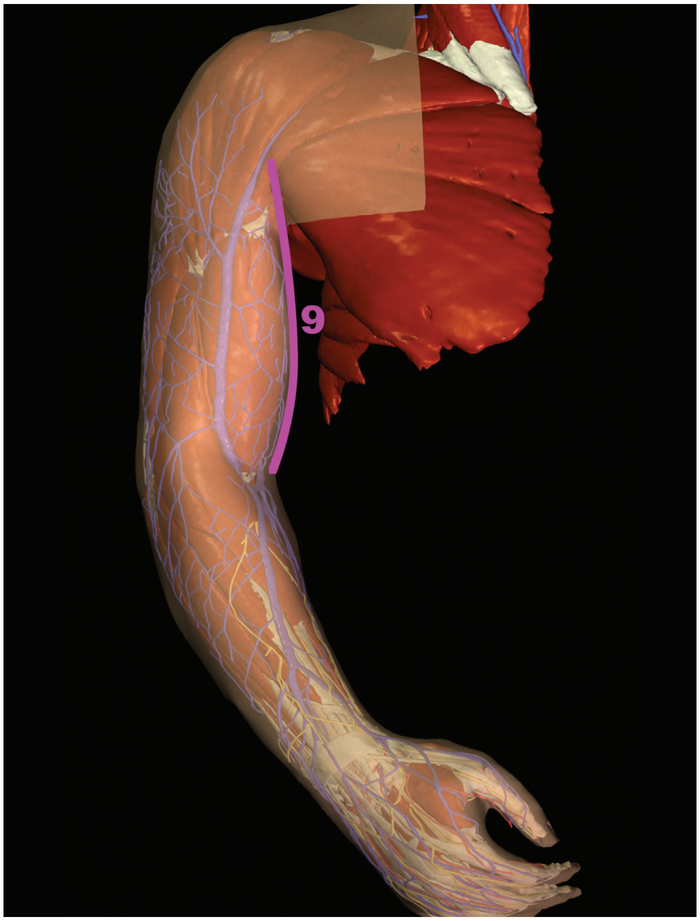

Figure 14. The brachium measures 9 cun from the superior limit of the anterior axillary crease to the elbow.

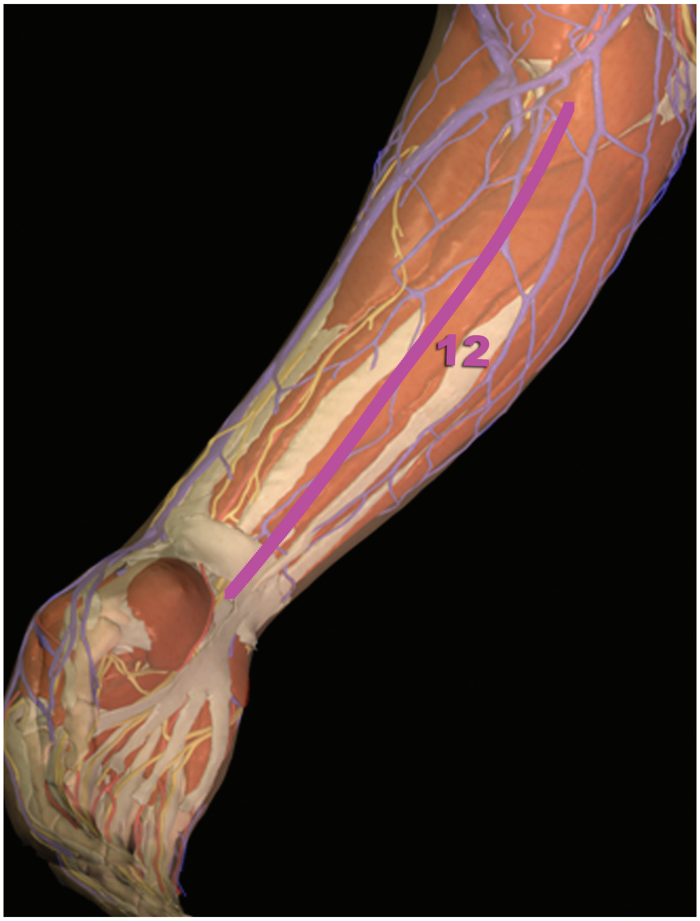

Figure 15. The cun count on the antebrachium is 12. Given the density of acupuncture points located on the antebrachium, this number frequently comes in handy.

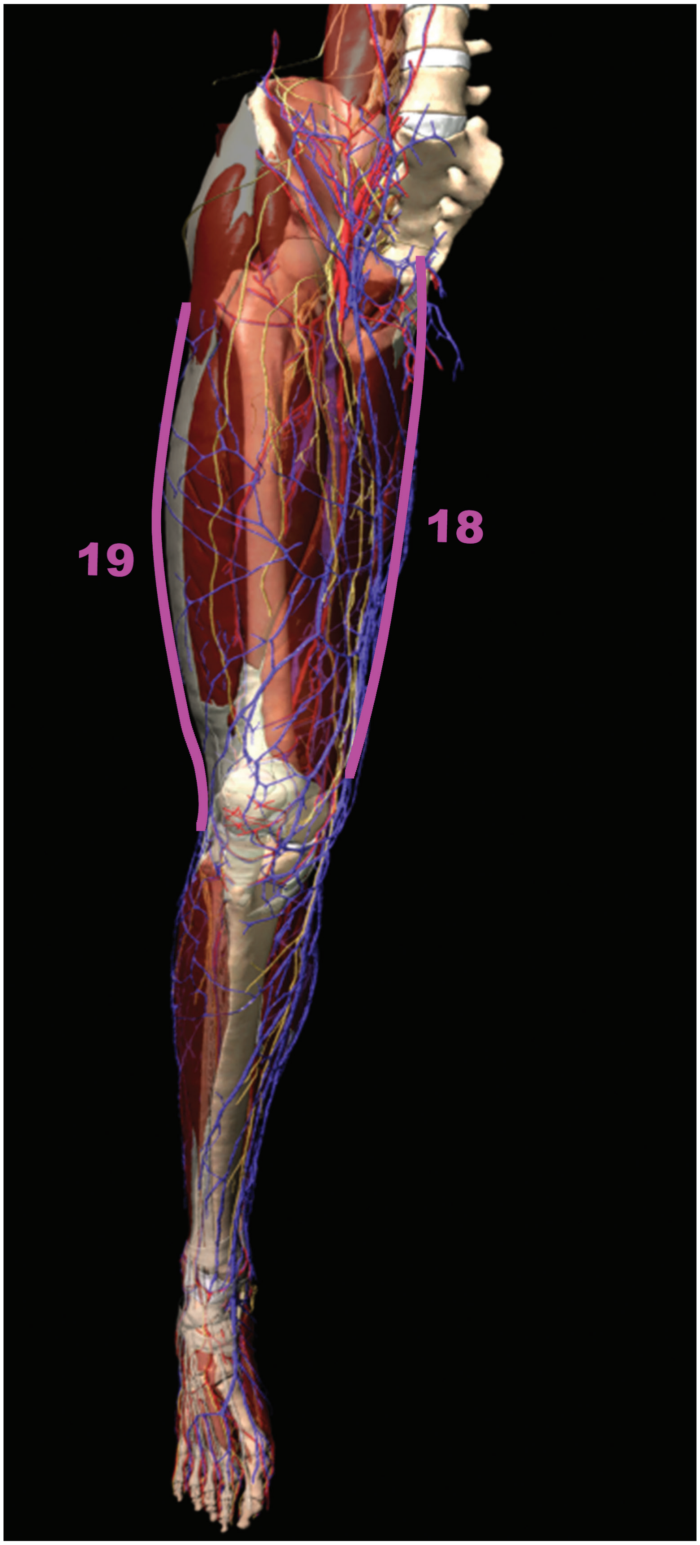

Figure 16. Pelvic limb cun measurements differ on the medial and lateral aspects of the limb, as indicated here for the thigh as well as in the following figure for the crus. This variance arises because the landmarks used in their calculation fall at different heights. On the thigh, the distance between the superior border of the pubic symphysis and the superior tip of the patella measures 18 cun. In contrast, the length of a line drawn from the lateral prominence of the greater trochanter to the popliteal crease equals 19 cun.

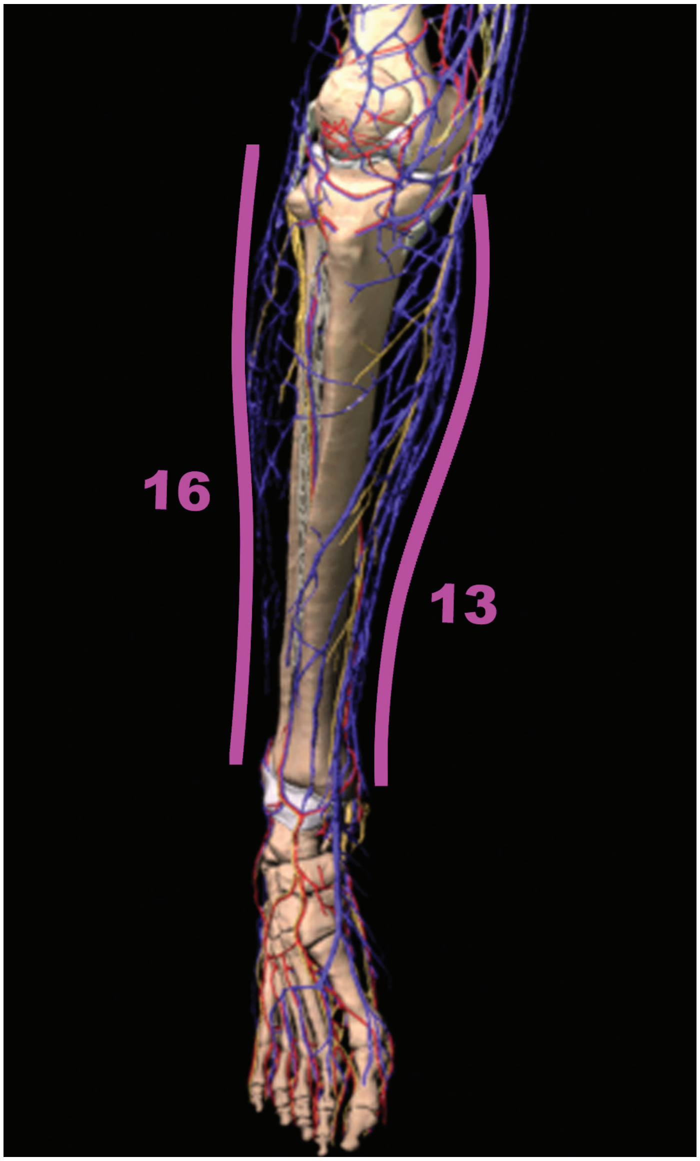

Figure 17. As with the thigh, the cun count on the crus depends on whether one is looking for points on the medial or lateral aspect of the limb. That is, the distance between the popliteal crease and the lateral malleolus is 16 cun while it is only 13 cun from the medial tibial condyle to the medial malleolus.

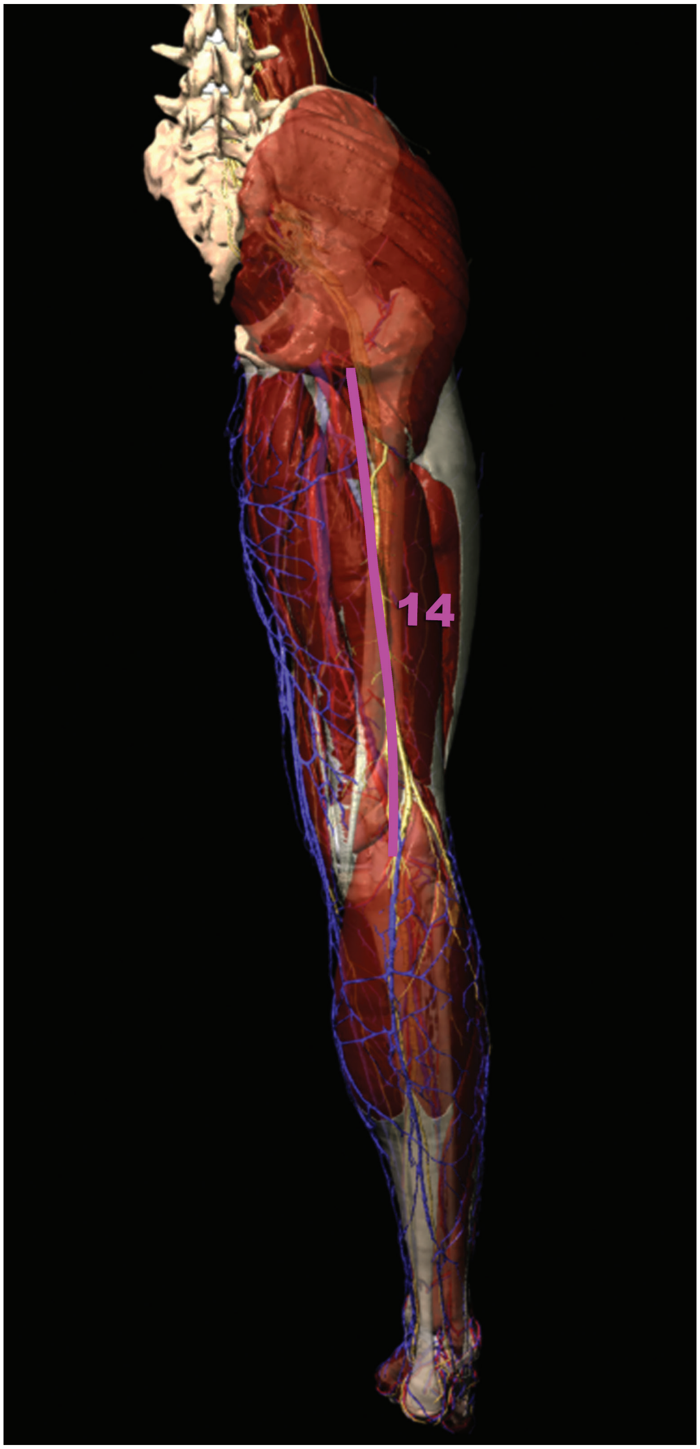

Figure 18. The cun count from gluteal fold to popliteal crease amounts to 14 cun.

Chapter 5:: Acupuncture Safety

Chapter Highlights

Compared to other medical treatments, acupuncture has a strong safety record.
Knowledge of anatomy is paramount in order to avoid injury.
Familiarity with the mechanisms of action of each modality included in a medical acupuncture treatment reduces the likelihood of adverse outcomes.

The link between safety and education in acupuncture is well known. As noted by various authors:

"Accidents arrive most often with those who are not fully trained.[1]"

"The distinction between [acupuncture] malpractice and normal practice is an important one because it is malpractice that is the cause of the most serious events including all fatalities.[2,3]"

"Adverse events due to errors of omission include failure to identify serious underlying pathology such as cancer, autoimmune disease, or subtle systemic pathology. Not only does this lead to failure to appropriately refer for a medical opinion and/or further investigations, but it allows the disease process to progress...The risks after failure to refer might be more significant than the other risks associated with acupuncture treatment…Acupuncturists, like conventional doctors, need to recognize both their own limits as well as those of the therapy, so as to minimize the risks of adverse events caused by failure to refer.[4]"

On the other hand, certain authors appear to over-emphasize the dangers, as noted in the following critique of a paper by Ernst et al[32] in which the authors were thought to have overstressed the risks of acupuncture by citing case reports:

"For safety, it is important to know the risks in the context of also knowing the frequency…Any medical intervention or any contact with an incompetent health care provider has the potential to cause damage…In Germany, acupuncture is mainly provided by physicians, and…[large] scale surveys have been conducted. One survey of 9429 German physicians performing more than 760,000 acupuncture treatments reported 2 instances of pneumothorax, one exacerbation of depression, an acute hypertensive crisis, a vasovagal reaction, and an asthma attack with hypertension and angina….To conclude, major adverse effects of acupuncture appear to be rare, and acupuncture is safe in competent hands."[33]

Acupuncture does indeed rank high in safety compared to most medical treatments though, admittedly, underreporting of adverse events likely skews the results.[5,6,7] Studies show that between 6% and 15% of patients experience minor side effects such as pain or bruising at the needling site, tiredness, and transitory exacerbation of their problem.[8,9] These events usually do not prevent patients from seeking further sessions.[10]

Case reports of serious adverse reactions or fatalities following acupuncture, while rare, prove that acupuncture can indeed injure patients.[11] Inadvertent organ puncture occurs when practitioners insert needles too deeply or at incorrect angles. Infections arise when needles penetrating unclean skin surfaces seed bacteria into the underlying tissues of immunocompromised patients. Aquapuncture, or point injection, may cause infection as well, especially when involving non-sterile herbs, extracts, or human placenta.[12,13,14] Needles that break or are embedded intentionally may migrate into organs or the nervous system and cause severe injuries.[15] Acupuncturists who needle pregnant patients must proceed cautiously; the exact rate of injury or miscarriage in this population following acupuncture remains unknown.[16,34] Risks include unintended changes in uterine contractility[17,18] and altered hormonal or prostaglandin levels.

Acupuncturists should know which conditions contraindicate treatment and refer patients elsewhere or consider utilizing a different modality. If acupuncture is indicated but risk factors exist, practitioners should take extra care to ensure safe treatment. (See Table 5-1.) Severely immune deficient patients may be unable to, as one author put it, "meet the challenge of the bacteremia that results when needles penetrate the skin."[19] Other patients with sensitive autonomic nervous systems patients may become syncopal from vasovagal responses.[20] When injury or exacerbations occur as a consequence of acupuncture treatment, practitioners must ensure that the patient receives appropriate medical follow-up and emergency treatment, if required.[21]

Table 5-1 Patient Risk Factors and Potential Adverse Events[22]

Risk factors	Potential Outcomes
• Hemophilia • Advanced liver disease, affecting clotting factor production • Patients taking anticoagulant medications or herbs • Deep needling over vessels[23]	Bleeding or bruising
• HIV • Diabetes • Patients receiving immunosuppressants, such as transplant patients • Skin infections	Infection
• Hypoglycemia • Debilitation • Fear or anxiety about needling • Advanced age	Vasovagal syncope, possibly even convulsive syncope[24]

Table 5-2 Patient Risk Factors and Potential Consequences[29]

Condition or Location	Needling precaution
Scalp	Avoid needling the scalp of infants with open fontanelles, or those with defects in the skull following injury or surgery
Orbit	Points such as ST 1, BL 1, and GB 1 lie close to the orbit and globe. Needling these points incorrectly could damage delicate tissues around or in the eye.
Trunk	Deep, perpendicular needling of points over the thoracic, abdominal, and pelvic regions could damage internal organs or major vessels.
Trapezius	Needling GB 21 deeply, especially in thin or poorly muscled individuals, may cause pneumothorax.
Sternum	Deep needling over the sternum, especially at the level of the 4th intercostal space at CV 17 may enter the pericardium or heart if a congenital sternal foramen exists.
Occipital region	Needling points at the base of the skull below the occiput may injure the brain stem, spinal cord, or vertebral artery if angled toward these structures and inserted deeply. Extra caution is advised when needling GV 16, GV 15, BL 10, and GB 20.[30] Ancient sources suggest that the safe needling direction for GB 20 is toward the contralateral globe; modern researchers suggest that needling should aim toward the apex of the nose. Needling direction for GV 15 and GV 16 has been recommended toward the mouth; see details concerning these points in the following chapters.[31]

Needling Depth and Direction

A medical acupuncturist should have strong familiarity with anatomy before treating patients. Ideally, one should be able to mentally visualize the structures encountered by the needle as the tip courses through skin, subcutaneous tissue and fat, muscle, vessels, organs, bones, etc. Doing so enables the practitioner to guide the angle and depth of needle insertion in a way that will avoid inadvertent puncture of organs, nerves, and major vessels.[25] The desired depth of needle placement depends on treatment targets as well as individual patient characteristics including adiposity, muscularity, and tissue fragility.[26,27,28] For example, the safe needling depth in a patient with a build like the individual represented in this book would differ dramatically from a frail eighty-six year old, ninety pound patient with cancer cachexia.

In any patient, deep, perpendicular needling over the neck, thorax, or abdomen could injure underlying structures. Vessels, nerves, eyes, spinal cord, and the foramen magnum are also vulnerable to injury by needle insertion. (See Table 5-2 for additional precautions.)

Summary

The safety measures recommended in this chapter narrowly focus on some of the more salient aspects of patient selection and needle insertion. To adequately grasp the breadth of safety concerns not only with MA, but also with EA, LA, and acupressure, an acupuncturist must attend a reputable program that enumerates all of the possible negative outcomes from treatment.

Section 3::

Twelve Paired Channels

Channel 1:: The Lung Channel (LU)

The Lung channel begins at LU 1 in the first intercostal space, medial to the shoulder. It loops over the anterior shoulder and proceeds down the lateral aspect of the biceps brachii muscle to the elbow. Between the elbow and the wrist, the Lung channel hugs the radius. Distal to the wrist, the channel remains on the radial aspect of the hand and ends on the radial side of the thumbnail at LU 11.

The Lung channel describes the course of the cephalic vein and its tributaries.

LU 8
LU 9
LU 10
LU 11

LU 1

Zhong Fu "Central Treasury"

On the lateral pectoral region, approximately at the level of the first intercostal space. LU 1 is found 1 cun inferior and slightly lateral to LU 2.

CAUTION: Needle carefully to avoid pneumothorax.[1] Puncture obliquely in a lateral direction. Deep needling in a medial direction may injure the lung.

Muscles

- **Pectoralis major muscle:** Adducts and medially rotates the humerus. Draws the scapula anteriorly and inferiorly.
- **Pectoralis minor muscle:** Stabilizes the scapula by drawing it against the thoracic wall.
- **Coracobrachialis muscle:** Assists in arm flexion and adduction.
- **Biceps brachii muscle:** Supinates the forearm; flexes the supinated forearm.

Clinical Relevance: Restricted motion of the shoulder, as in adhesive capsulitis (frozen shoulder), soft tissue injury impeding movement, arthritis or other causes of restricted range of motion, rehabilitation following surgery.

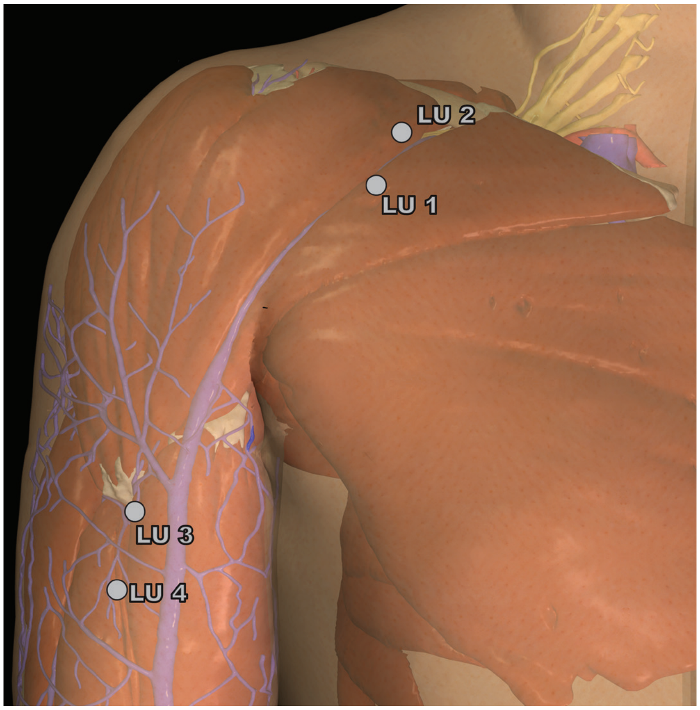

Figure 1-1. The Lung channel emerges from the chest at LU 1, near the entry of the cephalic vein into the deltopectoral groove, the deltopectoral triangle, and subsequently the axillary vein. The indications of LU 1 for lung problems likely relate to the fact that the point falls within the T1 dermatome; the lung receives sympathetic supply from several of the most cranial thoracic spinal cord segments. Also, freeing up the fascia in this region may promote air exchange by allowing fuller thoracic respiratory excursion. This then aids recovery from medical conditions related to or worsened by decreased chest wall mobility such as asthma and chronic obstructive pulmonary disease (COPD). LU 1 and LU 2 coincide with pectoralis major and minor trigger points.

Nerves

- **Supraclavicular nerves (C3, C4):** Supply the skin of the neck and part of the shoulder.
- **1st intercostal nerve (T1):** Supplies sensation to the skin in the first intercostal space.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle and contributes to pectoralis minor innervation via a loop connecting with the medial pectoral nerve.
- **Medial pectoral nerve (C8, T1):** Supplies the pectoralis minor muscle and a portion of the pectoralis major muscle.
- **Musculocutaneous nerve (C5-C7):** Innervates the muscles of the anterior compartment of the arm.
- **Axillary nerve (C5, C6):** Innervates the shoulder joint, skin overlying the inferior part of the deltoid muscle, and the teres minor and deltoid muscles.

Clinical Relevance: Loss of sensation in the anterior shoulder; impaired motor function of shoulder (adduction, internal rotation); instability of the scapula. Weakness or inability to flex and supinate the forearm (antebrachium).

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network of the hand. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Thoracoacromial artery:** A short arterial trunk that divides into four branches: the acromial, deltoid, pectoral, and clavicular arteries.
- **Axillary artery:** Supplies blood to the arm.
- **Axillary vein:** Lies medial to the axillary artery and arises from the union of the brachial veins.

Clinical Relevance: Impaired circulation to or from the thoracic limb; edema.

Lymphatics

- **Deltopectoral lymph nodes:** While most of the lymphatic vessels traveling alongside the cephalic vein enter the apical group of axillary lymph nodes, some enter the deltopectoral nodes.

Clinical Relevance: Deficient or faulty lymphatic drainage of thoracic limb; avoid needling enlarged lymph nodes.

Organ

- **Lung:** The lung lies medial to LU 1.

Clinical Relevance: Inadequate lung expansion or air expulsion as in asthmatic individuals. Caution required in all patients, especially those with local muscle atrophy or hyperexpansion of lungs ("barrel chest").

Indications and Potential Point Combinations

- **Respiratory disorders:** cough, dyspnea, bronchitis, pneumonia, tuberculosis, and asthma, chronic obstructive pulmonary disease:[2] LU 1, BL 13, BL 12, LU 7, LI 4.
- **Local pain or restricted motion of the shoulder, including the scapula:** LU 1, local trigger points depending on pain pattern, myofascial restrictions, and somatic dysfunctions in the spine.

Evidence-Based Applications

- Patients suffering from **dysphagia** following stroke who received electroacupuncture from LU 7 to LI 4, and from LU 1/ LI 15 to LI 18 demonstrated significantly greater swallowing function than did patients in the control group.[3]

LU 2

Yun Men "Cloud Gate"

In a depression below the lateral end of the clavicle, medial to the coracoid process and in the depression (or triangle) bordered by the deltoid muscle, pectoralis major muscle, and the clavicle.

CAUTION: Needle carefully to avoid pneumothorax.[1] Puncture obliquely in a lateral direction. Deep needling in a medial direction may injure the lung.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[2]

Fascia

- **Clavipectoral fascia:** Encloses the pectoralis minor and subclavius muscles. Envelops the muscles of the anterior thoracic wall.

Clinical Relevance: Fascial restriction Impairing shoulder mobility, evidence of nerve entrapment or irritability due to compression.

Muscles

- **Deltoid muscle:** The anterior part flexes and medially rotates the arm.
- **Pectoralis major muscle**: Adducts and medially rotates the humerus. Draws the scapula anteriorly and inferiorly.
- **Pectoralis minor muscle:** Stabilizes the scapula by drawing it against the thoracic wall, inferiorly and anteriorly.
- **Subclavius muscle**: Anchors and depresses the clavicle.
- **Serratus anterior muscle**: Holds the scapula against the thoracic wall, rotates, and protracts it. This muscle is used when "boxing" or reaching in a forward direction.

Clinical Relevance: Pain or weakness when adducting or medially rotating shoulder. Shoulder injury affecting joint integrity and/or stability.

Nerves

- **Supraclavicular nerves (C3, C4)**: Innervates the skin of the neck and part of the shoulder.
- **Nerve to the subclavius (C5, C6)**: Supplies the subclavius muscle.
- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle and contributes to pectoralis minor innervation via a loop connecting with the medial pectoral nerve.
- **Medial pectoral nerve (C8, T1):** Supplies the pectoralis minor muscle and a portion of the pectoralis major muscle.
- **Lateral cord of the brachial plexus (C5-C7):** Anterior divisions of the superior and middle trunks form the lateral cord of the brachial plexus.
- **Axillary nerve (C5, C6):** Innervates the shoulder joint, skin overlying the inferior part of the deltoid muscle, and the teres minor and deltoid muscles.
- **Long thoracic nerve (C5-C7):** Supplies the serratus anterior muscle.

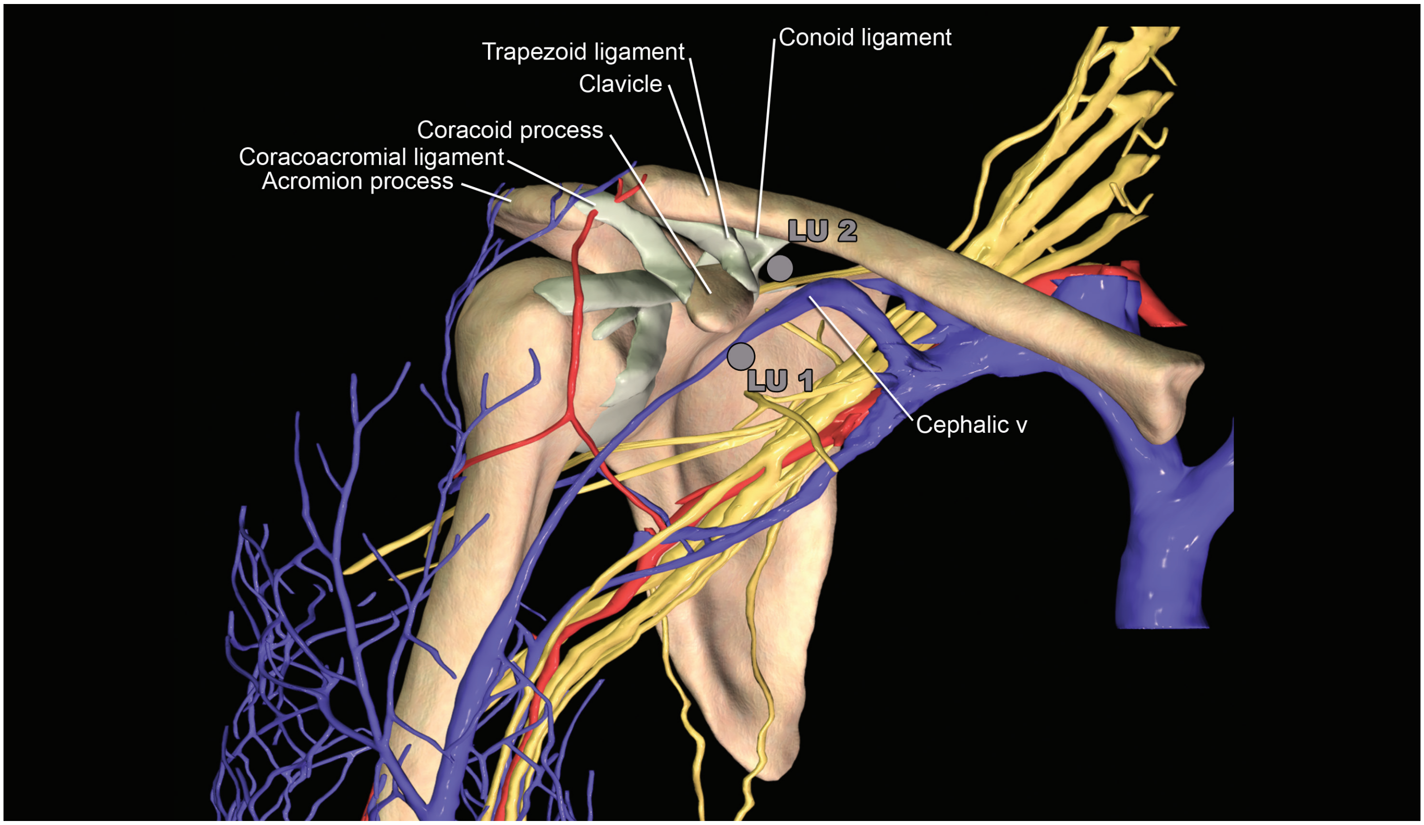

Figure 1-4. In keeping with the indications for LU 2 related to shoulder problems, this image illustrates the proximity of LU 2 to ligaments at the lateral end of the clavicle.

Figure 1-5. LU 2 as "Cloud Gate" alludes to the travel of the mists or clouds of Qi (as vital air and circulating nourishment) through the channels. LU 2 resides close to the lung and also over the cephalic vein, demonstrating the anatomic proximity of this point to both respiratory and vascular structures.

Clinical Relevance: Loss of sensation or motor function in the anterior shoulder vicinity.

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Thoracoacromial artery:** A short arterial trunk that divides into four branches: the acromial, deltoid, pectoral, and clavicular arteries.

Indications and Potential Point Combinations

- **Respiratory disorders:** cough, dyspnea, bronchitis, pneumonia, tuberculosis, and asthma: LU 2, LU 1, GV 14, BL 12, BL 13, LI 4.
- **Restricted motion of the shoulder, especially external rotation:** Needling LU 2 may affect restrictions in the axillary and clavipectoral fascia, thereby freeing structures contained within these planes and indirectly benefiting shoulder mobility and respiration. Consider additional points as indicated by the patient's restriction and palpation examination.

Evidence-Based Applications

- Patients who received EA (at LU 2, LU 7, and PC 6) prior to heart valve replacement surgery exhibited significantly lower serum troponin 1 release following aortic cross-clamp removal. This indicates potential benefit of EA in terms of reducing **reperfusion injury** from cardiac ischemia.[3]

LU 3

Tian Fu "Celestial Storehouse"

On the lateral aspect of the upper arm, 3 cun distal to the inferior limit of the anterior axillary fold, on the radial side of the biceps brachii muscle along the lateral bicipital groove, approximately at the level of insertion of the deltoid muscle. The tip of the nose is just able to reach this location.

Muscles

- **Biceps brachii tendon:** The biceps brachii muscle supinates the forearm and then can flex the elbow.
- **Brachialis muscle:** Flexes the elbow.

Clinical Relevance: Pain or weakness with elbow flexion or antebrachial supination.

Nerves

- **Musculocutaneous nerve (C5-C7):** Supplies the coracobrachialis, biceps brachii, and brachialis muscles. It continues as the lateral antebrachial cutaneous nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the cubital region, medial distal brachium, radial volar aspect of the forearm, and a small portion of the dorsal radial aspect of the distal forearm.

Clinical Relevance: Elbow flexor weakness, musculocutaneous nerve entrapment from local myofascial restriction, regional numbness or altered sensation.

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Anterior branch (also known as the radial collateral branch) of the deep artery of the arm (profunda brachii artery):** Participates in the anastomoses around the elbow.

Clinical Relevance: Degenerative joint disease of the elbow or other elbow dysfunction worsened by impaired oxygenation and elimination of metabolic end-products through circulatory waste removal.

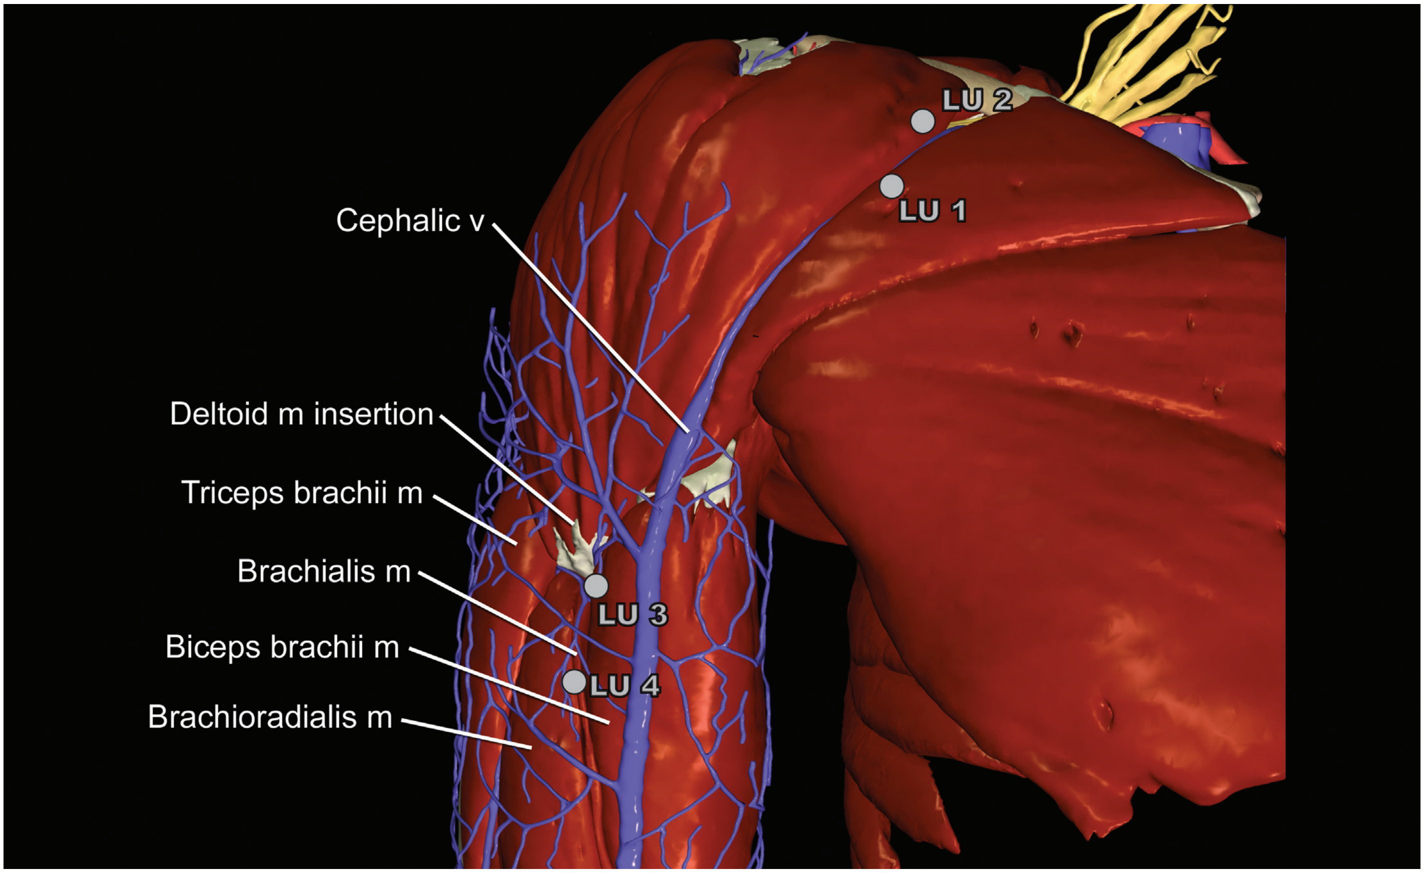

Figure 1-6. LU 3 and LU 4 reside on the lateral aspect of the biceps brachii muscle, in the lateral bicipital groove. The muscular intersections taking place in this region explain these points' value in treating myofascial restrictions and pain in the anterior brachium. LU 3, in particular, stands at the juncture of the myotendinous region of the biceps brachii and the insertion of the deltoid, heightening the potential for myofascial pain at this site. Considering the metaphoric actions attributed to this point, LU 3, as "Celestial Storehouse", receives the Qi (vital air and nutrients) that circulate in the cephalic vein coursing through this furrow.

Figure 1-7. This view provides another perspective of the relationship of LU 3 to the muscles shown in the previous figure.

Indications and Potential Point Combinations

- **Bicipital tendinitis or strain:** LU 3, LI 15, TH 14, other local tender points.
- **Arm pain:** As a biceps brachii trigger point, LU 3 should be examined for tenderness, along with other muscles in the brachium to determine the location of myofascial dysfunction or the potential source of arm pain, including arthrodial, osseous, and neural structures (rule out nerve entrapments).

LU 4

Xia Bai "Pressing White"

1 cun distal to LU 3 (or 4 cun distal to the axillary fold) on the radial side of the biceps brachii muscle, along the lateral bicipital groove.

Muscles

- **Biceps brachii tendon:** The biceps brachii muscle supinates the forearm and then can flex the elbow.
- **Brachialis muscle:** Flexes the elbow.

Clinical Relevance: Compromised elbow flexion; restricted elbow extension due to anterior compartment shortening.

Nerves

- **Musculocutaneous nerve (C5-C7):** Supplies the coracobrachialis, biceps brachii, and brachialis muscles. It continues as the lateral antebrachial cutaneous nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the cubital region, medial distal brachium, radial volar aspect of the forearm, and a small portion of the dorsal radial aspect of the distal forearm.

Clinical Relevance: Faulty elbow flexion due to motor nerve damage; pain or paresthesias in the cubital fossa and proximal, radial aspect of the forearm.

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Anterior branch (also known as the radial collateral branch) of the deep artery of the arm (profunda brachii artery):** Participates in the anastomoses around the elbow.

Clinical Relevance: Elbow edema or compromised circulation; conditions affecting vascular supply to distal extremities, such as functional peripheral vascular disease (PVD) from smoking, stress, cold exposure, work involving vibrating machinery or organic PVD due to inflammatory, thrombotic, atherosclerotic, infectious, or degenerative circumstances.

Indications and Potential Point Combinations

- **Pain in upper arm or shoulder**

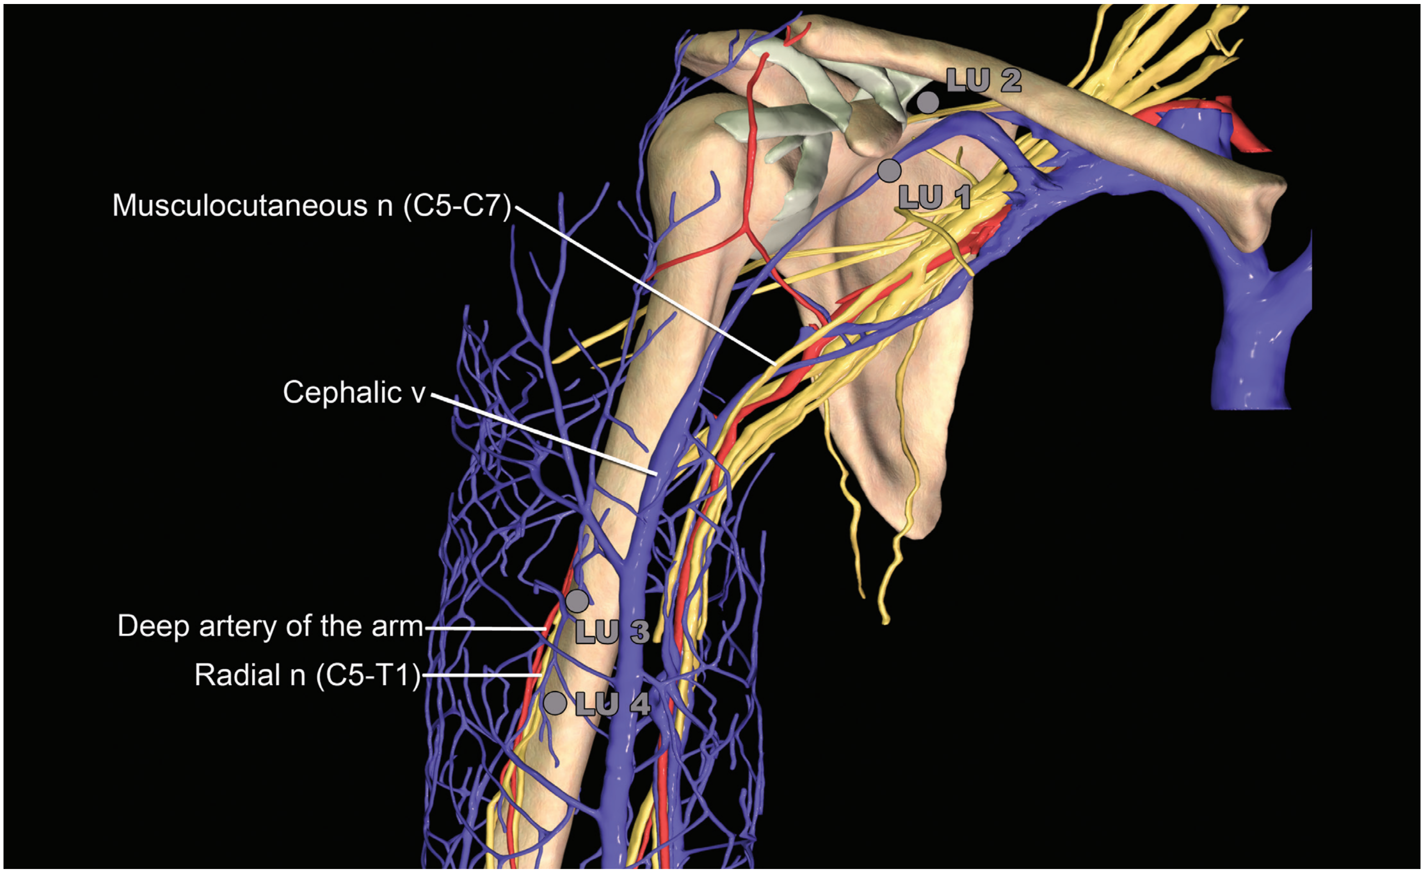

Figure 1-8. LU 3 and LU 4 relate to the musculocutaneous nerve, the deep artery of the arm, and the cephalic vein.

Figure 1-9. LU 4, adjacent to the brachialis muscle, addresses myofascial trigger points that arise in this location and radiate to the base of the thumb, near LU 10. Myofascial dysfunction in the brachialis that impinges upon the superficial sensory branch of the radial nerve may result in tingling, altered sensation, and numbness in the proximal thumb. (Simons DG, Travell JG, and Simons LS. Travell & Simons' Myofascial Pain and Dysfunction. The Trigger Point Manual. Volume 1. Upper Half of Body. 2nd edition. Baltimore: Williams & Wilkins, 1999. Pp. 661-662.) Its name, "Pressing White", comes from an ancient method of finding this point which involved pressing the lighter skin on the medial surface of the arm against the chest. The site at which the nipple met the brachium identified the location of LU 4.

LU 5

Chi Ze "Cubit Marsh"

At the cubital crease, on the radial (i.e., lateral) side of the tendon of the biceps brachii muscle. Locate with the elbow slightly flexed.

Muscles

- **Biceps brachii tendon:** The biceps brachii muscle supinates the forearm and then can flex the elbow.
- **Brachialis muscle:** Flexes the elbow.
- **Brachioradialis muscle:** Flexes the forearm at the elbow.

Clinical Relevance: Elbow pain, degenerative joint disease, local tendinitis.

Nerves

- **Musculocutaneous nerve (C5-C7):** Supplies the coracobrachialis, biceps brachii, and brachialis muscles. It continues as the lateral antebrachial cutaneous nerve.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the cubital region, medial distal brachium, radial volar aspect of the forearm, and a small portion of the dorsal radial aspect of the distal forearm.
- **Inferior lateral cutaneous nerve of the arm (C5, C6):** Supplies the lateral aspect of the distal brachium and proximal antebrachium. A branch of the radial nerve; it may be a branch of the posterior cutaneous nerve of the forearm in certain individuals.
- **Radial nerve (C5-C7):** Innervates the brachioradialis and extensor carpi radialis longus muscles.

Clinical Relevance: Weak elbow flexion; sensory loss or changes in the cubital fossa.

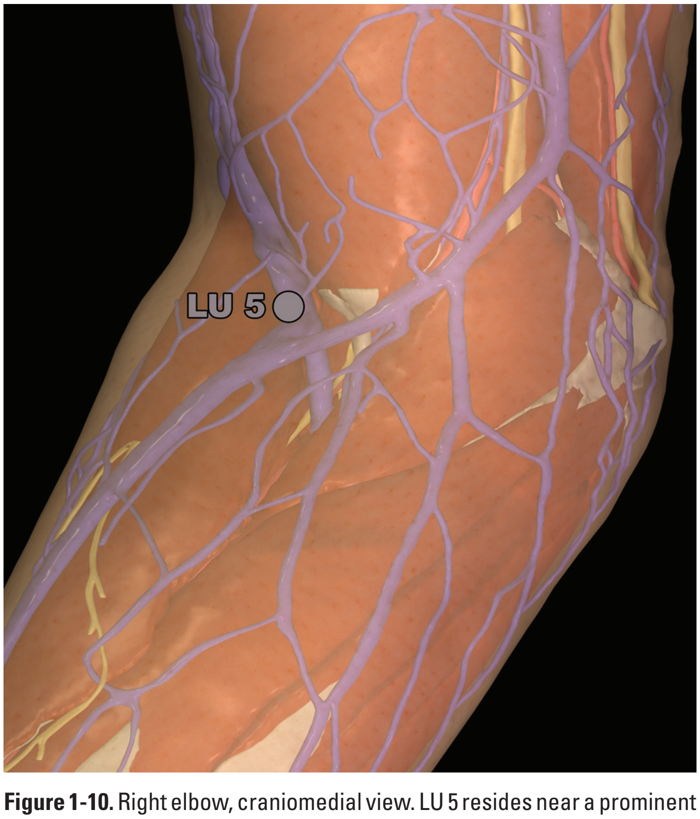

Figure 1-10. Right elbow, craniomedial view. LU 5 resides near a prominent venous intersection inthe cubital fossa. This shallow depression in the elbow signifying a confluence of figurative waterways warrants the name "Cubit Marsh".

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Radial recurrent artery:** Branches from the radial artery and returns to the elbow region to participate in the elbow anastomoses.
- **Anterior branch (also known as the radial collateral branch) of the deep artery of the arm (profunda brachii artery):** Participates in the anastomoses around the elbow.

Clinical Relevance: Elbow edema, altered vascular supply or drainage, peripheral vascular disease affecting elbow function, swelling of distal thoracic limb with impaired venous drainage.

Indications and Potential Point Combinations

- **Respiratory conditions:** dyspnea, cough, pleuritis, asthma, pharyngitis: LU 5, LU 1, BL 13, LI 4.
- **Pain in elbow and shoulder:** LU 5, LU 2, LI 15, LI 11, isolate particular causes of pain and address accordingly (i.e., joint, myofascial, or neuropathic pain).
- **Skin disorders:** LU 5, LU7, LI4, ST 36, GV 14.

Evidence-Based Applications

- A case series indicated that LU 5 and CV 23 effectively treated **pseudobulbar paralysis.**[1]
- Spinal reflexes that exist between elbow articular afferents and the cardiac sympathetic efferent nerve may provide the avenues for **somatoautonomic reflexes** attributed to LU 5.[2]
- Injection of vitamin K3 into LU 5 reduced episodes of mild to moderate **hemoptysis** in patients suffering from respiratory ailments.[3]
- Deep acupuncture at LU 5, TH 5, LI 10, LI 11, and LI 12 produced superior analgesia to superficial needling at these locations for the treatment of **lateral epicondylalgia.**[4]

Figure 1-12. LU 5 impacts strong movers of the thoracic limb that appear in this cross section.

LU 6

Kong Zui "Collection Hole" or "Biggest Hole"

On the anterior forearm, on the ulnar side of the brachioradialis muscle, on the line connecting LU 5 and LU 9; 5 cun below LU 5, 7 cun above LU 9. Or, divide the distance between LU 5 and LU 9 in half. Take LU 6 1 cun proximal to this midpoint.

Muscles

- **Brachioradialis muscle:** Flexes the forearm at the elbow.
- **Pronator teres muscle:** Flexes the forearm at the elbow, and pronates the forearm.
- **Flexor carpi radialis muscle:** Flexes and abducts the hand at the wrist.
- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints.
- **Extensor carpi radialis brevis tendon:** Extends and abducts the hand at the wrist joint.
- **Extensor carpi radialis longus tendon:** Extends and abducts the hand at the wrist joint.

Clinical Relevance: Weakness of the hand or wrist due to myofascial restriction or pain generated from somatic dysfunction of the forearm and digital flexors.

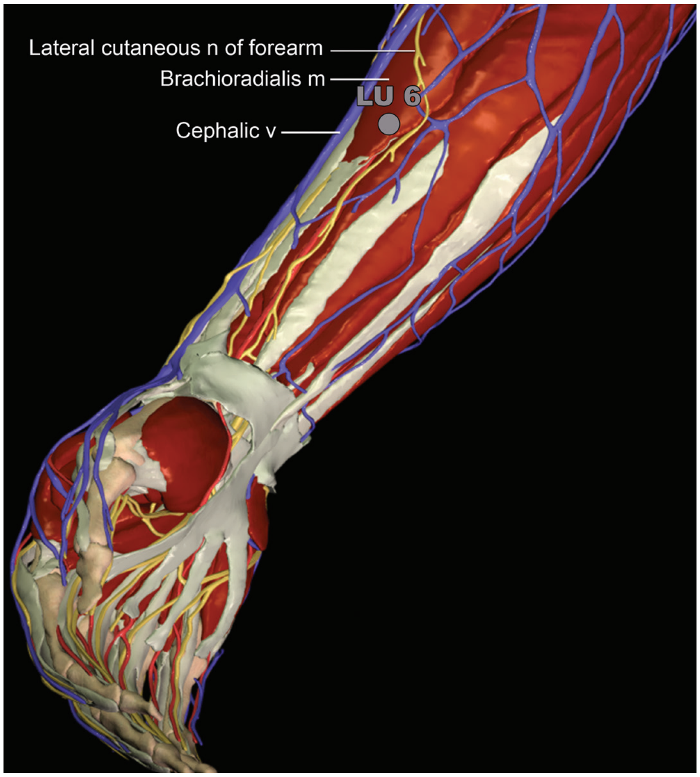

Figure 1-13. LU 6, the "Collection Hole" occupies a position on the flexor surface of the antebrachium where the examiner can palpate a "hole" alongside the brachioradialis muscle. The "Xi-Cleft" point of the Lung channel which, according to Chinese medical lore, collects blood and Qi. Anatomically, the Xi-Cleft points occur near myotendinous junctures, as seen here.

Nerves

- **Median nerve (C6-T1):** Innervates the flexors of the forearm, including the pronator teres, flexor digitorum superficialis and flexor carpi radialis muscles.
- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.
- **Radial nerve (C5-C7):** Innervates the brachioradialis and extensor carpi radialis longus muscles.
- **Deep branch of the radial nerve (C7, C8):** Supplies the extensor carpi radialis brevis muscle.

Clinical Relevance: Weakness in motor function of the forearm and digital flexors; nerve entrapment due to myofascial restriction in this area; sensory changes due to local or more proximal sources of nerve entrapment or irritation (including brachial plexus and spinal nerve egress through encroaching foramina).

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Radial artery:** Provides, with the ulnar artery, all of the blood to the hand. Provides muscular branches to the flexor and extensor muscles on the radial side of the forearm, the radial recurrent artery, the superficial palmar branch of the radial artery, the palmar carpal branch of the radial artery, and the dorsal carpal branch of the radial artery.
- **Radial veins:** These paired veins arise from the radial side of the deep venous arcade, which is associated with the deep palmar arterial arch.

Clinical Relevance: Circulatory dysfunction or edematous maladies affecting the distal thoracic limb.

Indications and Potential Point Combinations

- **Respiratory problems:** dyspnea, cough, bronchitis, asthma: LU 6, LU 7, LI 4, BL 12, BL 13, GV 14.
- **Throat problems: tonsillitis, laryngitis, pharyngitis:** LU 6, LI 11, LI 4, CV 22.
- E**lbow pain and restricted range of motion related to restriction in the forearm flexor muscles:** LU 6, LU 5, LU 7, associated trigger points.

Evidence-Based Applications

- Electroacupuncture at LI 4 and LU 6 **normalized the pattern of leukocytes**, and decreased heart rate.[1]
- Electroacupuncture delivered at the homeostatic points LI 4 and ST 36, as well LU 6 for salivary gland stimulation and ST 6 may have **lessened stress and fatigue** in female athletes. This was

LU 7

Lie Que “Broken Sequence” or “Divergent Breach”

In a depression on the radial aspect of the distal, volar antebrachium, 1.5 cun proximal to the wrist joint, just proximal to the styloid process of the radius.

Muscles

- **Brachioradialis tendon:** Flexes the forearm at the elbow.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius to the ulna.
- **Flexor pollicis longus muscle:** Flexes the phalanges of the thumb.
- **Flexor carpi radialis tendon:** Flexes and abducts the hand at the wrist.
- **Extensor pollicis brevis muscle:** Extends the thumb’s proximal phalanx.
- **Abductor pollicis longus tendon:** Abducts the thumb and extends it at the carpometacarpal joint:
- **Extensor carpi radialis brevis tendon:** Extends and abducts the hand at the wrist joint.

Clinical Relevance: Restricted, painful, or weak wrist movement. Impaired motor function of the thumb due to pain or disuse.

Nerves

- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.

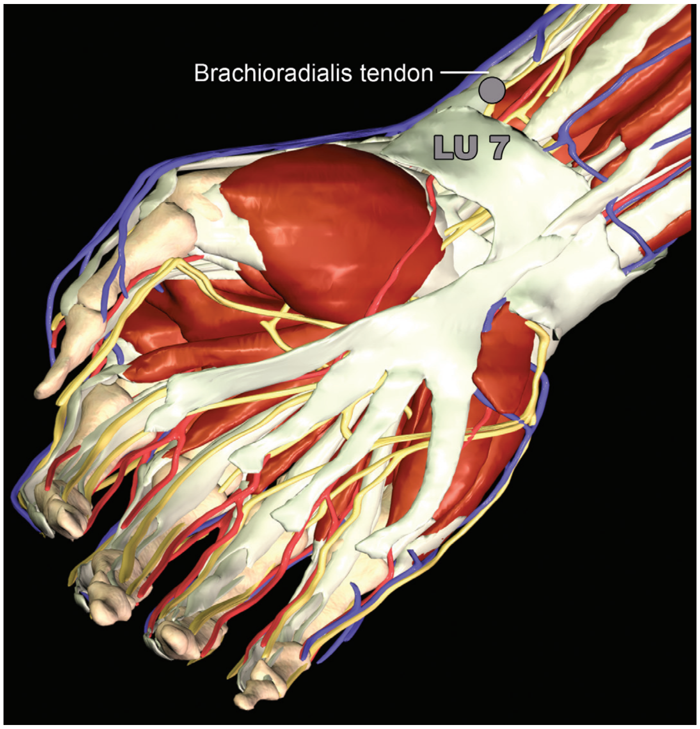

Figure 1-16. LU 7 lies in the groove along the ulnar aspect of the brachioradialis tendon, as shown here.

- **Radial nerve, superficial branch (C6-C8):** Innervates the skin over the palmar region surrounding the 1st metacarpophalangeal joint and the dorsum of the radial aspect of the hand (except for the dorsal fingertips, which are innervated by the median nerve) as well as the radial aspect of the wrist.
- **Radial nerve, deep branch (C7, C8):** Innervates the extensor carpi radialis brevis muscle.
- **Radial nerve (C5-C7):** Innervates the brachioradialis and extensor carpi radialis longus muscles.
- **Median nerve (C6-T1):** Innervates the flexors of the forearm.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve, the posterior interosseous nerve innervates the abductor pollicis longus muscle, the extensor pollicis longus and brevis muscles, the extensor digitorum, the extensor digiti minimi, and the extensor carpi ulnaris muscles, and the extensor indicis muscle.
- **Anterior interosseous nerve (C8, T1):** From the median nerve, the anterior interosseous nerve innervates the flexor pollicis longus and the pronator quadratus muscles.

Clinical Relevance: Nerve damage or entrapment affecting motor function of the thumb, hand, or wrist. Sensory changes or loss impacting the radial aspect of the wrist or thumb. Neuropathic or other sources of pain in the wrist or thumb.

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Radial artery and the communications between the deep palmar arterial arch and the palmar carpal arches:** These anastomoses provide collateral circulation at the wrist.
- **Radial veins:** Paired veins arise from the radial side of the deep venous arcade, which follows the deep palmar arterial arch.

Clinical Relevance: Peripheral vascular disease or lymphatic congestion affecting the distal forearm, wrist, and/or hand. Do not needle through edematous tissue; select another method of neuromodulation such as manual lymphatic drainage or laser therapy.

Indications and Potential Point Combinations

- **Upper and lower respiratory problems, including rhinitis, tonsillitis, pharyngitis, cough:** LU 7, LU 5, LI 4, LI 11, BL 12, BL 13, BL 23, GV 14.
- **Skin disorders:** LU 7, LI 14, LI 11, GV 14, ST 36.
- **Worry, grief, sadness:** LU 7, LR 3, HT 7, HT 3, GV 20.
- **Neck pain and stiffness:** LU 7, local cervical trigger points, GB 21, BL 23.
- **Pain in the trigeminal nerve distribution:** LU 7, LI 4, local facial points as indicated by the pain presentation.

B

Figure 1-17A and B. "Broken Sequence", for LU 7, refers to the divergent neurovascular pathways that progress toward LI 4 on the dorsum of the hand, shown more clearly in Figure 1-17A.

Evidence-Based Applications

- Laser acupuncture at LU 7, LI 4, GB 14, and GB 20 reduced **chronic tension headache**.[2]
- Electroacupuncture at LI 4, LU 7, GV 14, GV 20, the thoracolumbar midline point San Tai and the lumbosacral midline point Baihui (veterinary) demonstrated a reduction of minimum alveolar concentration (MAC) of isoflurane by 16.7% in dogs. Acupunc-ture-assisted anesthesia thus **potentiated the anesthetic effects of volatile anesthetic agents**.[3]
- Following a series of acupuncture treatments, men with **poor sperm quality** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[4]
- Patients suffering from **dysphagia** following stroke who received electroacupuncture from LU 7 to LI 4, and from LU 1/LI 15 to LI 18 demonstrated significantly greater swallowing function than did patients in the control group.[5]
- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma** patients.[6,7]
- Patients who received EA (at LU 2, LU 7, and PC 6) prior to heart valve replacement surgery exhibited significantly lower serum troponin 1 release following aortic cross-clamp removal. This indicates potential benefit of EA in terms of reducing reperfusion injury from cardiac ischemia.[8]
- Acupuncture at LU 7, ST 8, GB 4, GB 5, GB 20, and GV 14 afforded large cost-savings for **migraineurs** who would otherwise have missed work, according to a controlled trial testing acupuncture against conventional drug treatment.[9]
- Acupuncture at LU 7, ST 40, GB 20, and GV 20, as well as plum-blossom hammer tapping at GV 14, alleviated vertigo and related symptoms in a majority of patients in a case series of patients with **vertebrobasilar ischemic vertigo.**[10]

LU 8

Jing Qu “Channel Ditch”

On the radial, volar aspect of the wrist, 1 cun above the wrist crease (and also LU 9, at the level of the joint), in the depression between the radial artery and the styloid process of radius.

Muscles

- **Brachioradialis tendon:** The brachioradialis muscle flexes the forearm at the elbow.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius to the ulna.
- **Flexor carpi radialis tendon:** Flexes and abducts the hand at the wrist.
- **Abductor pollicis longus tendon:** Abducts the thumb and extends it at the carpometacarpal joint.

Clinical Relevance: Tendonitis or myofascial dysfunction affecting wrist mobility, strength, and comfort. Tendinitis or local soft tissue restriction impairing thumb function and causing pain.

Nerves

- **Brachioradialis tendon:** The brachioradialis muscle flexes the forearm at the elbow.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius to the ulna.
- **Flexor carpi radialis tendon:** Flexes and abducts the hand at the wrist.
- **Abductor pollicis longus tendon:** Abducts the thumb and extends it at the carpometacarpal joint.

Clinical Relevance: Tendonitis or myofascial dysfunction affecting wrist mobility, strength, and comfort. Tendinitis or local soft tissue restriction impairing thumb function and causing pain.

Vessels

- **Cephalic vein:** Ascends from the radial portion of the dorsal venous network. Courses along the radial aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein (which lies anterior to the brachial artery) in the anterior elbow, then passes across the anterior elbow to join with the basilic vein. Ultimately empties into the axillary vein.
- **Radial artery and the communications between the deep palmar arterial arch and the palmar carpal arches**: these anastomoses provide collateral circulation at the wrist. Chinese pulse diagnosis assesses the quality of the impulse at various positions along the radial artery, including locations over LU 7, LU 8, and LU 9. System wide changes such as aging and stress alter histological features in the arterial wall, leading to changes in pulse quality.[2,3] For example, the Chinese pulse diagnosis of “liver qi stagnation” associated with emotional turmoil, taut pulse, and chest pain would equate with sympathetic nervous system arousal in contemporary biomedicine.
- **Radial veins:** These paired veins arise from the radial side of the deep venous arcade, which is associated with the deep palmar arterial arch.

Clinical Relevance: Circulatory insufficiency or compromise that

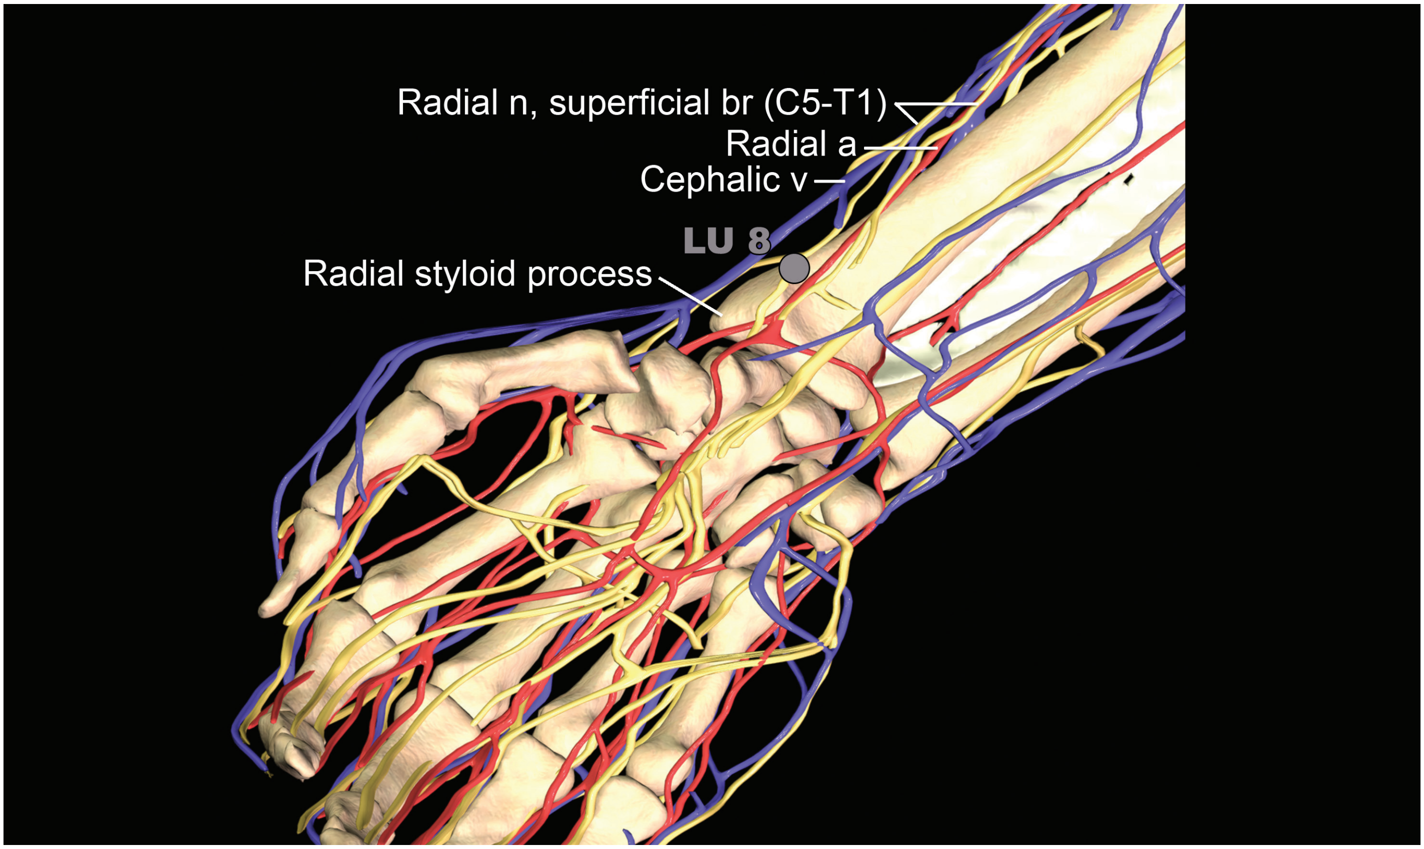

Figure 1-18. LU 8, the “Channel Ditch” point snugs up close to the prominence that forms the radial styloid process.

limits oxygenation of distal tissues and elimination of metabolic waste and fluid accumulation.

Indications and Potential Point Combinations

- **Wrist pain:** LU 8 if tender. Check also PC 7, other local points. Identify myofascial restrictions in brachioradialis muscle and flexor pollicis longus (for referred pain).

References

LU 9

Tai Yuan "Great Abyss"

On the radial, volar (palmar) aspect of the wrist in the depression on the radial side of the radial artery, distal to the styloid process of radius. Level with HT 7 at the proximal border of the pisiform bone. On the ulnar aspect of the abductor pollicis longus tendon.

Muscles

- **Abductor pollicis longus tendon:** Abducts the thumb and extends it at the carpometacarpal joint.
- **Extensor pollicis brevis tendon:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.
- **Flexor pollicis longus muscle:** Flexes the phalanges of the thumb.
- **Brachioradialis tendon:** Flexes the forearm at the elbow.
- **Flexor carpi radialis tendon:** Flexes and abducts the hand at the wrist.

Clinical Relevance: Wrist pain from degenerative joint disease, other joint ailments; myofascial dysfunction of wrist tendons; loss of wrist function. Thumb pain, myofascial dysfunction in the thenar eminence impacting thumb mobility, strength, comfort.

Nerves

- **Lateral antebrachial cutaneous nerve, from the musculocutaneous nerve (C6, C7):** Supplies the radial volar aspect of the forearm, and a portion of the dorsal radial aspect of the distal forearm.

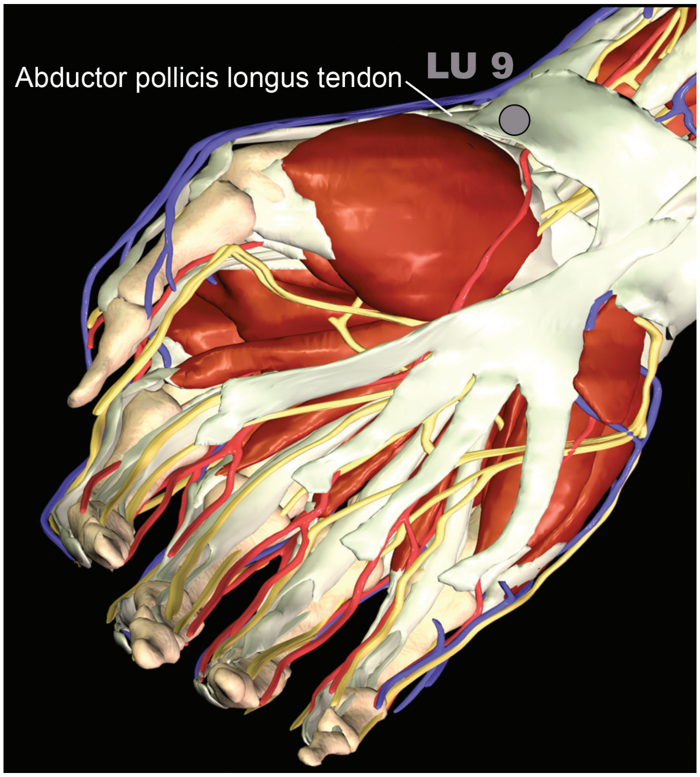

Figure 1-19. This image shows LU 9 on the ulnar aspect of the abductor pollicis longus tendon.

- **Radial nerve (C5-C7):** Innervates the brachioradialis and extensor carpi radialis longus muscles.
- **Radial nerve, superficial branch (C6-C8):** Innervates the skin over the palmar region surrounding the 1st metacarpophalangeal joint and the dorsum of the radial aspect of the hand (except for the dorsal fingertips, which the median nerve supplies) as well as the radial aspect of the wrist. Somatic afferent stimulation from the superficial radial nerve resets sympathetic discharges.[1]
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve, the posterior interosseous nerve innervates the abductor pollicis longus muscle, the extensor pollicis longus and brevis muscles, the extensor digitorum, the extensor digiti minimi, and the extensor carpi ulnaris muscles, and the extensor indicis muscle.
- **Anterior interosseous nerve (C8, T1):** From the median nerve, the anterior interosseous nerve innervates the flexor pollicis longus and the pronator quadratus muscles.
- **Median nerve (C6, C7):** Innervates the flexor carpi radialis muscle.

Clinical Relevance: Wrist or radiating thumb pain; neuropathic, inflammatory, or entrapment-related nerve irritation.

Vessels

- **Radial artery and the communications between the deep palmar arterial arch and the palmar carpal arches:** These anastomoses provide collateral circulation at the wrist.
- **Radial veins:** Arise from the deep venous arcade, associated with the deep palmar arterial arch.

Clinical Relevance: Peripheral vascular disease states affecting circulatory supply to the hand; generalized autonomic tone related to input from sympathetic afferents in the periphery; compression of local neurovascular supply from tension in the flexor retinaculum or other connective tissue or bone overgrowth in this region of the wrist.

Indications and Potential Point Combinations

- **Respiratory problems:** Cough, sore throat, bronchitis, asthma, emphysema: LU 9, LU 7, LU 2, BL 13, ST 36.
- **Pain in the forearm or wrist:** Try to identify the source; consider LU 9 for local pain or pain along the radial aspect of the forearm; add myofascial trigger points.
- **Epistaxis:** LU 9, LI 4, ST 44, GV 20.

Evidence-Based Applications

- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary Raynaud's syndrome, demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[2]
- Acupuncture at LU 9, LU 11, LI 1, PC 9, TH 1, HT 9, SI 1, KI 1, SP 1, LR 1, ST 45, GB 44, BL 67, LI 4, CV 17, ST 36, ST 40, BL 58, SP 6, KI 7, and moxibustion at GV 14 resulted in rapid improvement in a 13-month old child with staphylococcal-infected skin wounds following a poor 50-day response to antibiotics.[3]

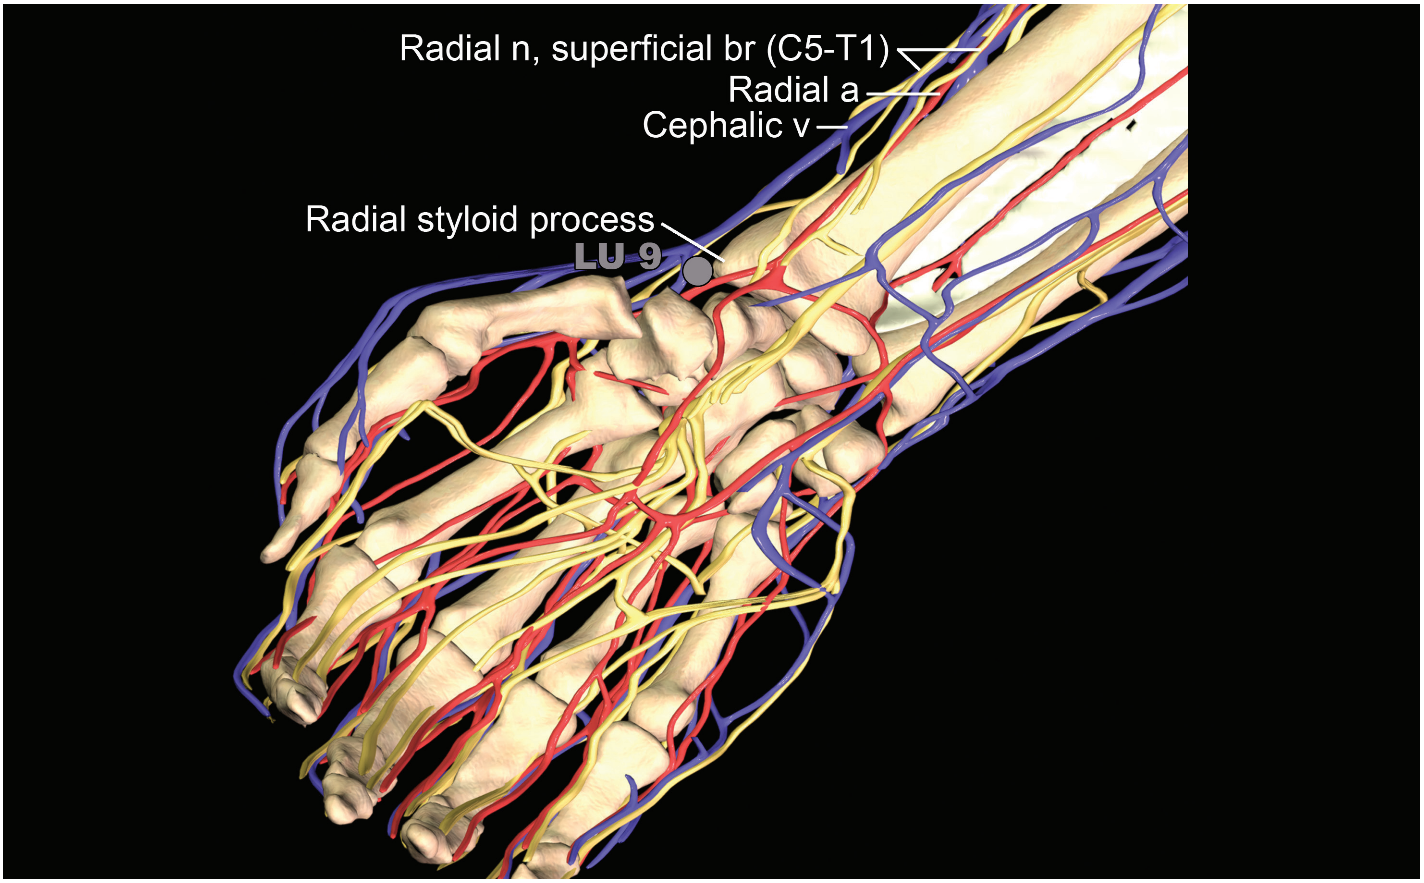

Figure 1-20. LU 9 lines up with the radiocarpal joint. Its name, “Great Abyss” connotes the deep depression one palpates at this site. The classical indication of LU 9 as an influential point for vasculature probably reflects the influence of local sympathetic afferents on blood flow through autonomic nervous system modulation.

LU 10

Yu Ji "Fish Border"

On the thenar eminence, midway along the shaft of the first metacarpal bone, in a depression along the dorsal/palmar skin border.

Muscles

- **Abductor pollicis brevis muscle:** Abducts the thumb and extends the thumb at the carpometacarpal joint.
- **Opponens pollicis muscle:** Allows thumb opposition as when picking up an object.
- **Flexor pollicis brevis muscle:** Flexes the thumb.

Clinical Relevance: Loss of thumb strength and opposability, whether due to myofascial trigger points, arthritic pain, or muscle atrophy.

Nerves

- **Radial nerve, superficial branch (C6-C8):** Innervates the skin over the palmar region surrounding the 1st metacarpophalangeal joint and the dorsum of the radial aspect of the hand (except for the dorsal fingertips, which are innervated by the median nerve) as well as the radial aspect of the wrist
- **Palmar cutaneous branch of the median nerve (C6-C8):** Innervates the skin over the radial palmar region.
- **Median nerve, recurrent branch (C6-T1):** Innervates the thenar muscles: the abductor pollicis brevis, flexor pollicis brevis (superficial part), and opponens pollicis.
- **Ulnar nerve (C6, C7):** Supplies the deep part of the flexor pollicis brevis muscle.

Clinical Relevance: Thumb pain or numbness, carpal tunnel syndrome or other nerve entrapment pathologies.

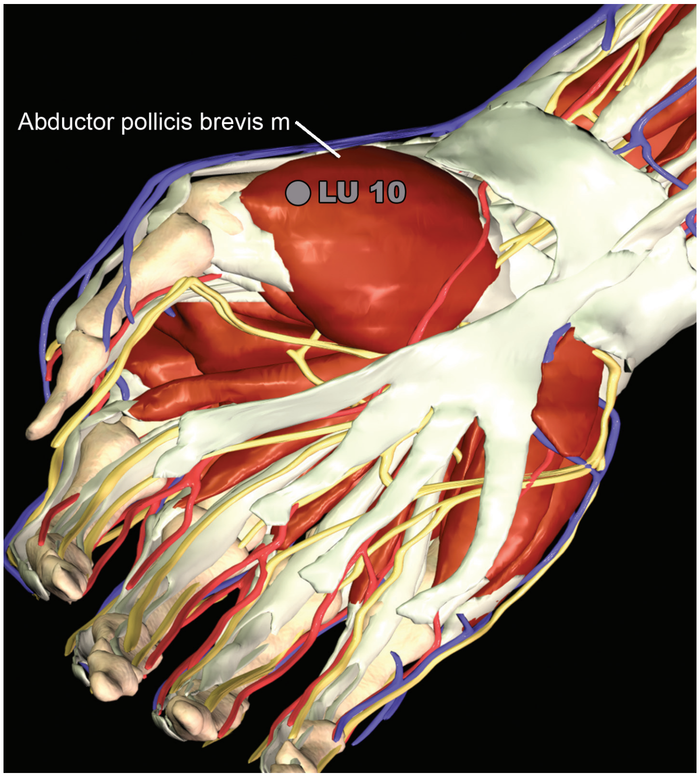

Figure 1-21. LU 10 resides at the midpoint of the first metacarpal bone along the dorsal-palmar border. The term "Fish Border" connotes the fish-like shape of the thenar eminence. Its "border" identifies the dorso-palmar skin junction where the color changes.

Vessels

- **Superficial palmar arch venous branches:** Its radial branches drain to the cephalic vein.
- **Deep venous arcade:** This series of anastomosing venous arches gives rise to the deep veins of the forearm, including the radial veins. The deep venous arcade parallels the deep palmar arterial arch.
- **Communications between the deep palmar arterial arch and the palmar carpal arches:** These anastomoses provide collateral supply to the wrist.

Clinical Relevance: Peripheral vascular disease, including Raynaud's disease or syndrome; thumb joint malfunction due to deficient oxygen perfusion.

Indications and Potential Point Combinations

- **Respiratory conditions, especially associated with inflammation:** cough, hemoptysis, fever, laryngitis, pharyngitis, tonsillitis, pneumonia, chest restriction, dyspnea: LU 10, LI 4, ST 36, KI 6, LI 11, BL 13, BL 14, GV 14.
- **Thumb pain from arthritis:** LU 10, LU 7, LI 4, local points as indicated by palpation.

Evidence-Based Applications

- A 40-minute treatment of needling at LU 10 and LU 6 reportedly delivered an "immediate **antiasthmatic** effect".[1]

Figure 1-22. This oblique section identifies the relationship between LU 10 and muscles of the thenar eminence, so often beset by myofascial restriction leading to thumb pain. LU 10 corresponds to the motor point of the abductor pollicis brevis muscle. (Liu Y, Varela M, and Oswald R. The correspondence between some motor points and acupuncture loci. *Am J Chin Med.* 1975;3(4):347-358.)

LU 11

Shao Shang "Lesser Merchant"

On the radial side of the base of the thumb nail, the width of a Chinese leek leaf (approximately 0.1 cun; more like a chive than a leek) from the corner of the nail.

Nerves

- **Distal network of the proper palmar digital n. , from the median nerve (C6):** Provides sensation and sympathetic supply to the thumb.

Clinical Relevance: Local sensory loss; systemic autonomic dysfunction impacted through actions of the nervi vasorum and sympathetic supply.

Vessels

- **Distal network of proper palmar digital artery:** Participates in the arteriovenous network at the tip of the finger. No longitudinal arteries run along the dorsum; instead, branches from the proper palmar digital artery anastomosed along like links in a chain.

The most distal arterial branches turn into twigs on either side of the base of the nail that anatomose with their opposing partners, creating an arch at the nail matrix where the endpoints of the channels sit. Thus, these "ting" or endpoints associate intimately with small, physiologically active vessels.

- **Distal network of proper palmar digital vein:** Participates in the arteriovenous network at the tip of the thumb.
- **Note on the neurovascularization of the fingers:** The pattern of vessels supplying the hand creates a complex area of study that still poses challenges for anatomists. Morphologic variations in the neurovascular supply for the thoracic limb may result from factors related to limb position during development.

Comparative anatomy note: Quadrupeds such as the dog exhibit a highly developed counter-current heat exchange system with abundant arteriovenous anastomoses and notable dermal venous plexuses in their footpads. These anatomic features give the paw the capacity to resist damage from contact with cold surfaces. Vasodilation of proximal vessels in the limb bolsters blood supply to the surface of the pad on the paw.[5]

Clinical Relevance: Problems with local or systemic autonomic tone and thermal regulation.

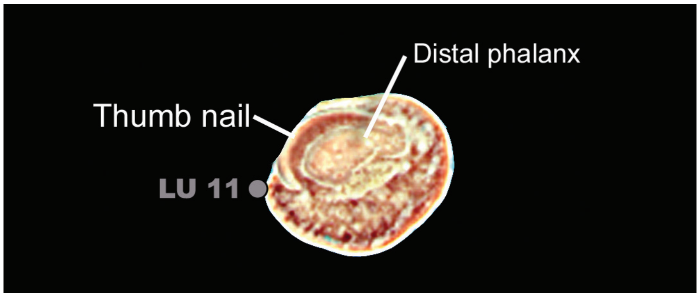

Figure 1-23. Note the small lumen of the vessel underlying LU 11, next to the thumb nail. This tiny location as the most distal point placement qualifies LU 11 for the name "Lesser Merchant".

Indications and Potential Point Combinations

- **Typically used alone, LU 11 may help restore breathing, promote resuscitation, stop febrile seizures:** Needle or bleed to break fever and sweat patient

Evidence-Based Applications

- Bloodletting at LU 11 or LI 1 in children may prevent and treat laryngospasm occurring post-extubation.[6]
- Acupuncture at LU 9, and all the ting points (LU 11, LI 1, PC 9, TH 1, HT 9, SI 1, KI 1, SP 1, LR 1, ST 45, GB 44, BL 67), as well as LI 4, CV 17, ST 36, ST 40, BL 58, SP 6, KI 7, and moxibustion at GV 14 resulted in rapid improvement in a 13-month old child with staphylococcal-infected skin wounds following a poor 50-day response to antibiotics.[7]
- Figure 1-23. Note the tiny vessel extending from the thumb nail to LU 11. The point's small size suits the name "Lesser Merchant".

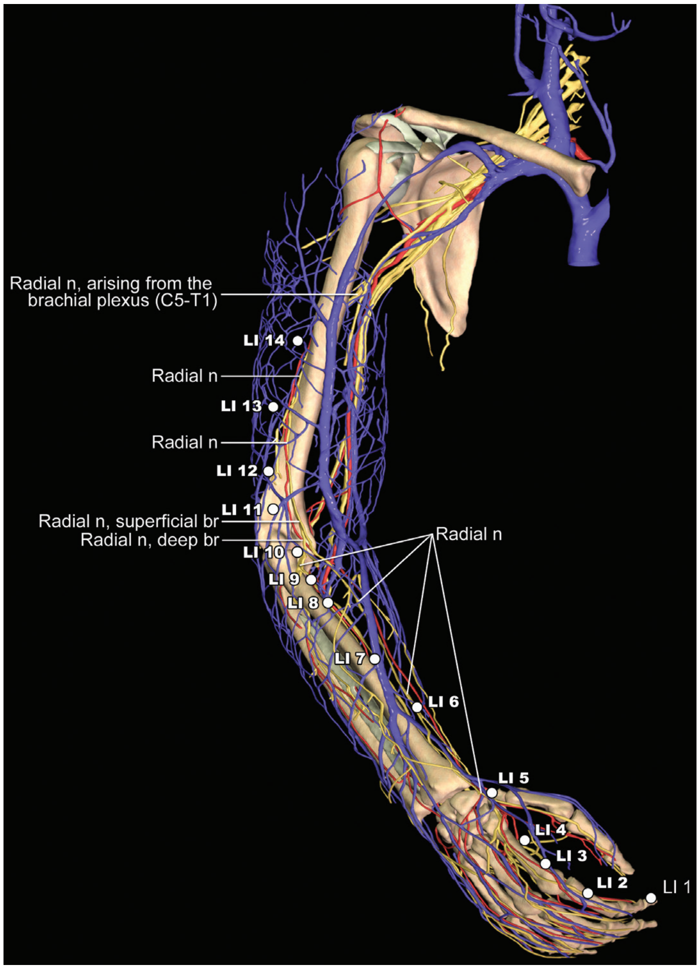
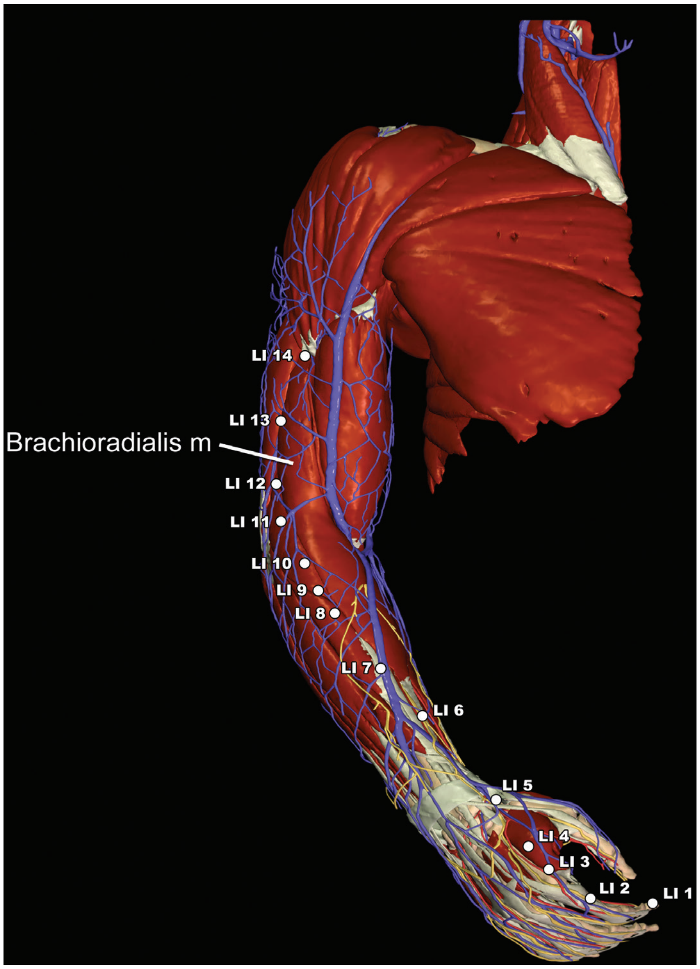
LI 1

The LI channel commences at LI 1 on the radial side of the index finger. Following its course toward the nose, the LI line follows the pathway determined by the radial nerve to the mid-humerus. After reaching the acromion and then the face, the LI channel arrives at LI 20, lateral to the contralateral naris.



The tight relationship between the radial nerve and the LI channel becomes apparent when tracing the course of both from the mid-humerus to the index finger.



The brachioradialis muscle overlies the radial artery and nerve as it travels from brachium to wrist. Thus, the LI channel describes the course of both the radial nerve and the brachioradialis muscle.

Chinese Medicine doctrine claims that several LI points such as LI 4 and LI 11 "clear heat", especially in the head, neck, or cranial thorax. The metaphor "clearing heat" suggests anti-inflammatory, anti-sympathetic effects.

The LI channel commences at LI 1 on the radial side of the index finger.

After tracking the radial nerve to the mid-humerus, the LI line jumps to the shoulder, ascends the neck, and crosses under the nose to LI 20, the only channel to start on one side of the body and end on the other.

The generalized (rather than local neural or musculoskeletal) effects of stimulating points on the LI channel involve somatosympathetic pathways that reflex through the trigeminocervical segments of the spinal cord.[1,2,3] These neuroanatomic connections explain the frequent appearance of LI points for toothache, migraine, facial myofascial and sinus pain.[4,5,6,7,8,9]

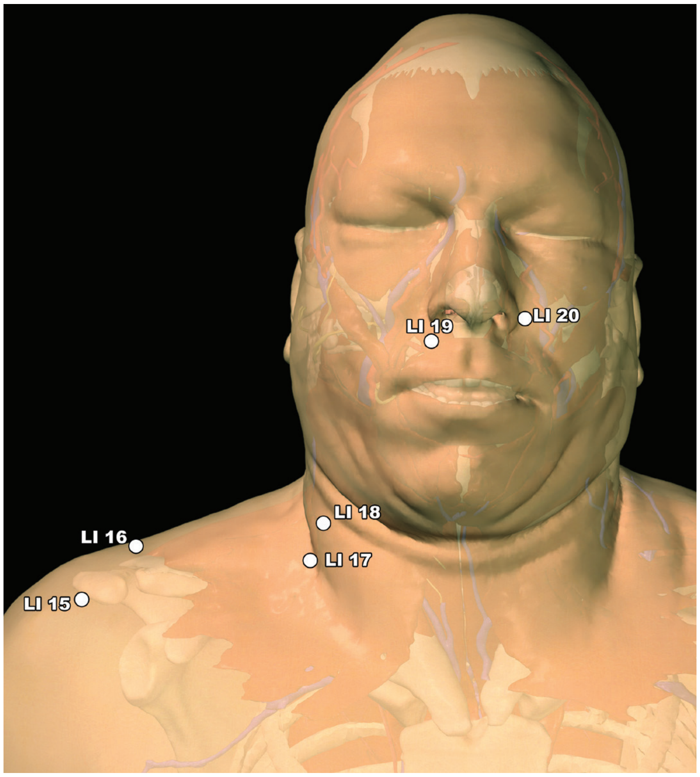
LI points treat afflictions of the face and mouth through neuroanatomic connections between cervical and trigeminal neurons. Trigeminocervical reflexes account for the spreading and referred pain patterns from migraine and sinusitis discomfort. Afferent stimulation from medical acupuncture and related techniques modulates nociceptive input to the CNS, activating endogenous analgesic mechanisms such as endogenous opioidergic systems in the periaqueductal gray.



Topographical locations of LI points on the head, neck, and shoulder region.

LI 1

Shang Yang "Metal Yang"

On the radial side of the base of the nail of the index finger, the width of a Chinese leek leaf from the corner of the nail.

Nerves

- **Median nerve (C6):** Distal branches of the proper palmar digital nerve from the median nerve provide sensation and sympathetic input to the index finger.
- **Note about fingertip nerve supply:** The highly sensate fingertip contains sensory end organs between the volar digital skin and the nail that allows for accurate prehension of small objects.[5] The proper palmar digital nerve accompanies its arterial companion on the ventral ulnar and radial aspects of the fingers. Proximal to the base of the nail fold, the nerve divides and sends branches into the pulp of the finger as well as to the nail bed.[1] These nerve fibers provide only part of the sensory supply to the nail bed. Additional sensation is supported by structures known as "glomus bodies", identified as intertwining clusters of fine vessels and nerves. Glomus bodies modulate blood flow to the fingertip by controlling fine vessel diameter. The close proximity of glomus bodies to the nail allows for thermal transfer, similar to the heat exchange that takes place when one places a hand against a window pane.[2] Too, the finger's tip serves as a temperature regulator, highlighting the indications of Ting points such as LI 1 for heat stroke and fever.

Clinical Relevance: Distal index finger numbness or nerve damage; intensive activation of autonomic reflexes influencing attention and arousal as well as heat distribution; autonomic reflexes to the head and neck through trigeminocervical reflexes.

Vessels

- **Distal network of dorsal branches of proper palmar digital artery of the radial side of the index finger:** Distributes to the fingertip.
- **Dorsal digital artery and vein:** Participate in the arteriovenous network at the tip of the finger.
- **Nailfold and fingertip microvasculature:** Blood flow in the nail bed and surrounding region correspond to circulatory dynamics. Microcirculatory pressure and blood flow at the distal points of acupuncture channels may afford insight into a patient's general wellness.[4] Too, microvessels in the nailfold capillary beds may serve as microcosmic windows into the macrocosmic alterations reflected in the vasculature, characteristic of conditions such as autoimmune rheumatic diseases.[3] Blood flow in the nail bed and surrounding region reflects circulatory dynamics; measuring microcirculatory pressure and blood flow may yield insights into a patient's overall cardiovascular status.[4] The highly sensate fingertip contains sensory end organs between the volar digital skin and the nail that allows for accurate prehension of small objects.[5] The fingertip also serves as a temperature regulator, highlighting the indications of Ting (most distal channel points) such as LI 1 for heat stroke and fever.

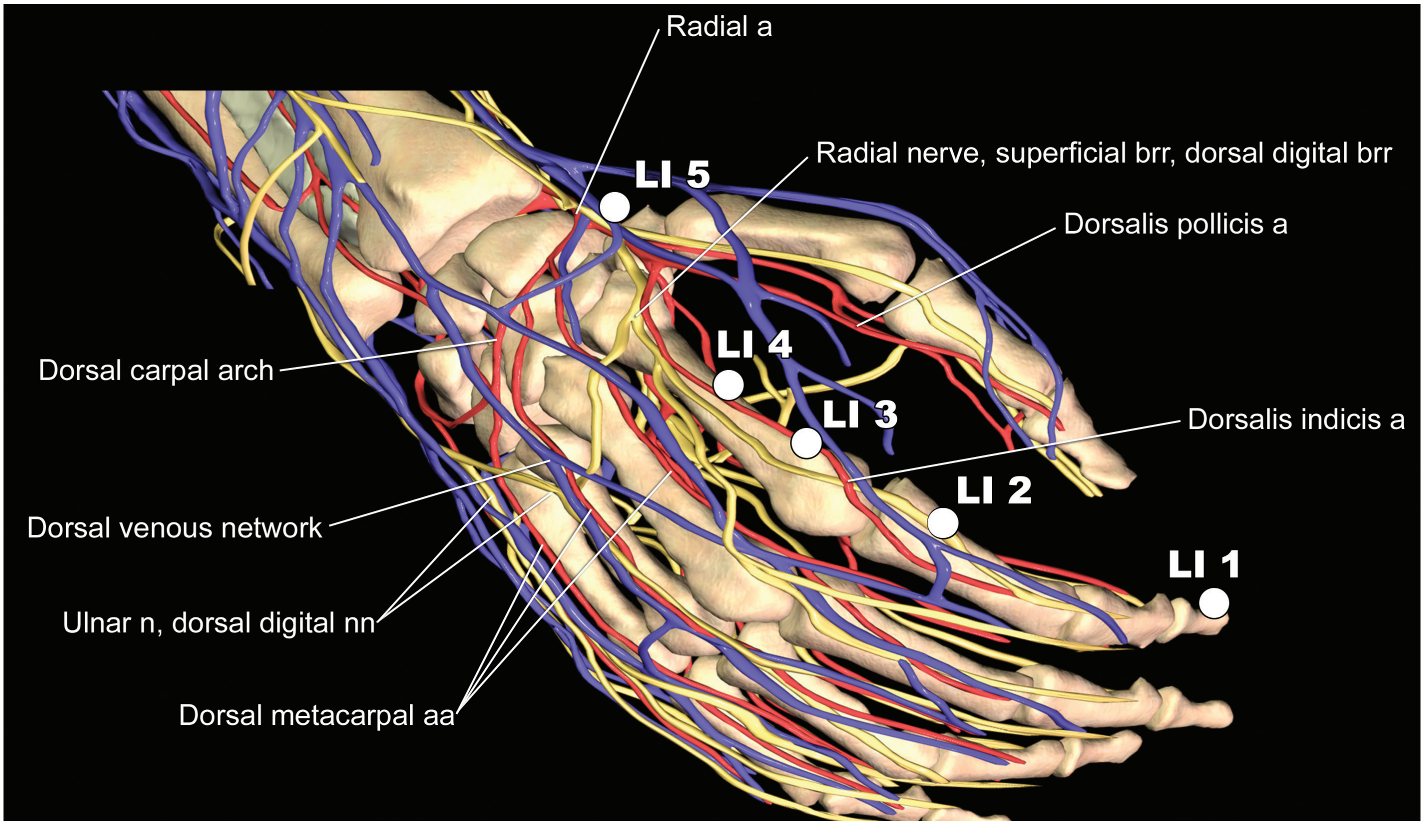


Figure 2-1. LI 1 exemplifies a typical "Ting" point or most distal point on the channel, lying just lateral to the base of the nail in densely neurovascular tissue. The microcirculatory network in this region offers an opportunity to deliver clinically relevant hemodynamic and temperature regulation through acupuncture treatment.

Clinical Relevance: As noted above in the section on LI 1 nerve supply, the rich arteriovenous supply of the distal finger produces profound autonomic shifts in hemodynamics and alertness, seemingly disproportionate to the vessels' sizes in this region.

Indications and Potential Point Combinations

- **Conditions of inflammation, hyperthermia, or sympathetic nervous system arousal, including heat stroke, fever, pharyngitis, tonsillitis, conjunctivitis:** LI 1, LI 4, LI 11, GV 14, ST 36.
- **Numbness of index finger:** LI 1, LI 2, LI 3, LI 4.
- **Coma:** LI 1, HT 9, consider other ting points.

Evidence-Based Applications

- Bloodletting at LU 11 or LI 1 in children may prevent and treat **laryngospasm** occurring post-extubation.[6]
- Acupuncture at LU 9, and all the ting points (LU 11, LI 1, PC 9, TH 1, HT 9, SI 1, KI 1, SP 1, LR 1, ST 45, GB 44, BL 67), as well as LI 4, CV 17, ST 36, ST 40, BL 58, SP 6, KI 7, and moxibustion at GV 14 resulted in rapid improvement in a 13-month old child with **staphylococcal-infected skin wounds** following a poor 50-day response to antibiotics.[7]

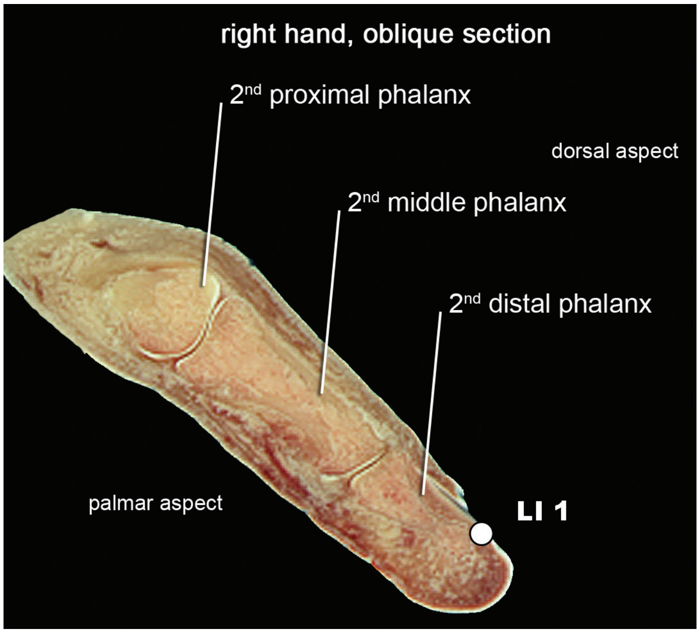

Figure 2-2. This section through the index finger shows the proper palmar digital artery coursing along the volar (palmar) surface toward the network of capillaries at the tip. LI 1, "Shang Yang", refers to the relation of this point to a Yang (hollow) organ and the metal phase, or element, both ideas from Chinese medicine. The association of organs and acupuncture points with the five phases (or elements) of metal, water, wood, fire, and earth is quaint but abstract and, as such, untestable.

LI 2

Er Jian "Second Space"

On the radial side of the index finger, in a depression distal to the 2nd metacarpophalangeal joint, at the junction of the base and the shaft of the proximal phalanx, along the dorsal/palmar skin junction.

Tendons

- **First dorsal interosseous tendon:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and flex the metacarpophalangeal joints.
- **First lumbrical tendon:** Flexes the digit at the metacarpophalangeal joint and extends the interphalangeal joint.
- **Extensor digitorum tendon:** Extends the fingers at the metacarpophalangeal joints and the hand at the wrist.
- **Extensor indicis tendon:** Extends the index finger and helps extend the hand. Allows the index finger to operate independently of other fingers.

Clinical Relevance: Difficult or painful index finger movement; degenerative joint disease or other causes of arthralgia and arthrosis of the 2nd metacarpophalangeal joint, leading to tendinopathy; overuse syndromes.

Nerves

- **Radial nerve (C5-C8):** Supplies all muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of this deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm innervates the skin of the posterior the forearm to the wrist. The posterior antebrachial cutaneous nerve innervates the lateral arm, posterior forearm, and wrist.
- **Median nerve (C6-T1):** Gives motor function to the lumbrical muscles of the 2nd and 3rd digits and sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (i.e., thumb, forefinger, and middle finger), the radial aspect of the ring finger, and the adjacent palmar areas. The median nerve branches into the recurrent (thenar), lateral, medial, and palmar cutaneous nerves. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

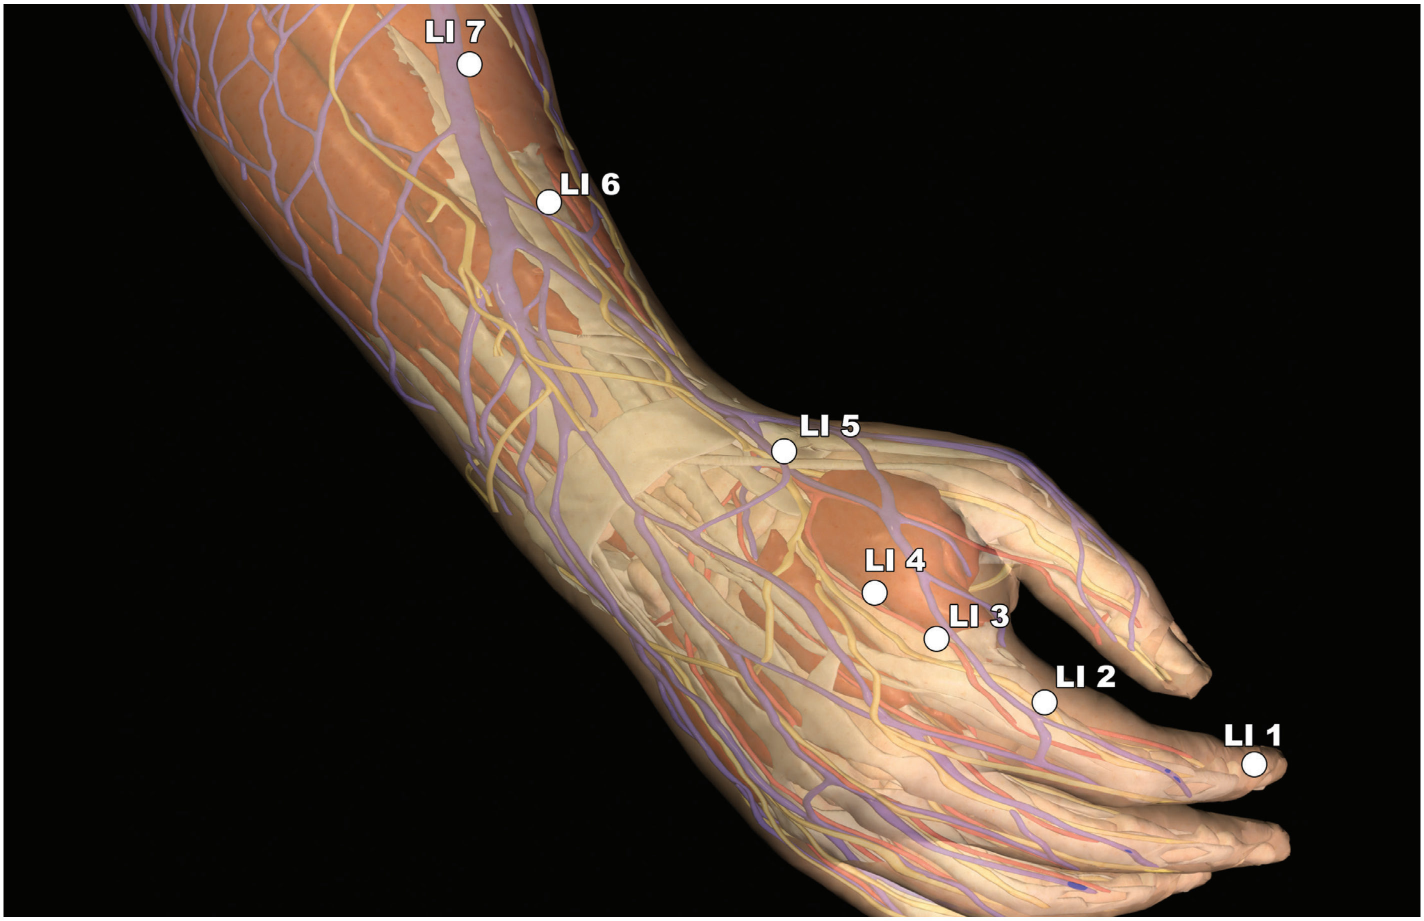

Figure 2-3. LI 2, "Second Space", the second point on the channel, sits at the metacarpophalangeal joint on the second (index) finger.

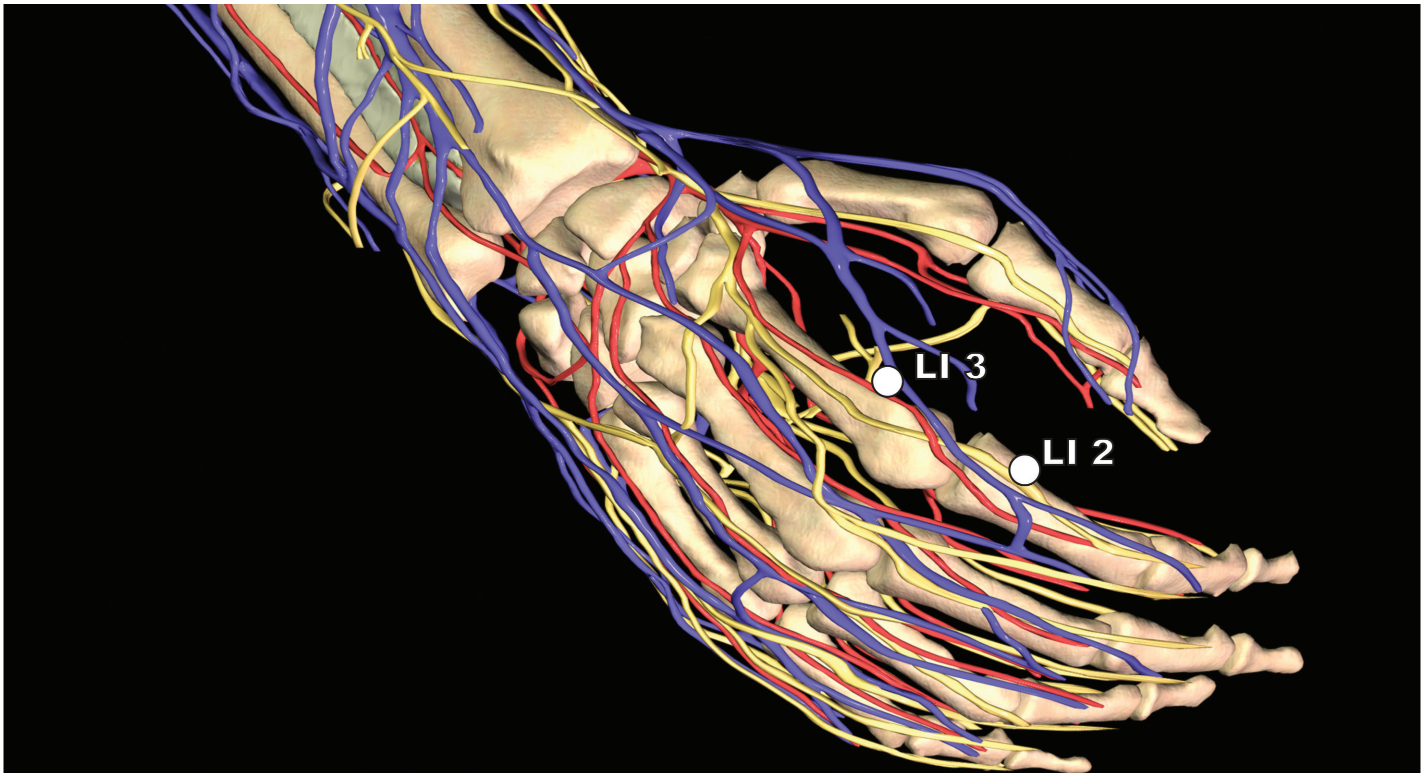

Figure 2-4. Both LI 2 and LI 3 treat local joint pain based on their periarticular locations. Their dense sympathetic and somatic sensory supply confer added effects on autonomic regulation.

Clinical Relevance: Carpal tunnel syndrome or other causes of median nerve entrapment; radial nerve injury, post-traumatic recovery of index finger injury; overuse syndromes involving the 2nd metacarpophalangeal joint.

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Radialis indicis artery:** Arises from either the radial artery or the princeps pollicis artery and passes along the radial aspect of the index finger.
- **Dorsalis indicis artery:** Supplies the dorsal radial aspect of the index finger.
- **Dorsal digital artery and vein:** Circulates blood to and from the fingertip, respectively.
- **Proper palmar digital artery and vein:** Distributes to the fingertip.

Clinical Relevance: Peripheral vascular disease affecting index finger mobility and/or tissue health.

Indications and Potential Point Combinations

- **Index finger arthralgia at the metacarpophalangeal joint:** LI 2, LI 3, LI 4.

Evidence-Based Applications

- Unilateral, manual acupuncture at LI 2 produced bilateral activation of the insula and operculum (sites in the brain associated with gustation and salivation) as well as improved saliva production compared to stimulation of a sham site.[1]

References

LI 3

San Jian "Third Space"

On the radial side of the index finger, in a depression proximal to the 2nd metacarpophalangeal joint and head of the 2nd metacarpal bone, at the dorsal/palmar skin junction.

Muscles

- **First dorsal interosseous muscle:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and flex the metacarpophalangeal joints.
- **First lumbrical muscle:** Flexes the digit at the metacarpophalangeal joint and extends the interphalangeal joint.
- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints. Also flexes the proximal phalanges at the wrist and metacarpophalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.

Clinical Relevance: Difficult or painful index finger movement; restricted apposition of the thumb and forefinger (index finger); degenerative joint disease or other causes of arthralgia and arthrosis of the 2nd metacarpophalangeal joint, leading to tendinopathy; overuse syndromes.

Nerves

- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.
- **Median nerve (C6-T1):** Innervates all of the thenar muscles, except for the adductor pollicis and deep head of the flexor pollicis brevis. Supplies the lumbrical muscles for the 2nd and 3rd digits and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), the radial aspect of the ring finger, and the adjacent palmar areas. Four branches arise from the median nerve: the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

LI 1

Figure 2-5. LI 3, "Third Space", identifies this third point on the LI channel.

- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles, i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It splits into four branches: the palmar cutaneous, dorsal, superficial, and deep branches of the ulnar nerve. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring fingers. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal little finger, the ulnar side of the ring finger, and the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), as well as the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Carpal tunnel syndrome or other causes of median nerve entrapment; radial nerve injury, post-traumatic recovery of index finger injury; overuse syndromes involving the 2nd metacarpophalangeal joint; dysfunction of intrinsic muscles of the hand from ulnar or median neuropathy.

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Radialis indicis artery:** Arises from the radial artery or the princeps pollicis artery and passes along the radial aspect of the index finger.
- **Dorsalis indicis artery:** Courses along the dorsal radial aspect of the index finger.

Clinical Relevance: Peripheral vascular disease affecting index finger mobility and/or tissue health.

Indications and Potential Point Combinations

- **Index finger arthralgia at the metacarpophalangeal joint:** LI 3, LI 2, LI 4.

LI 4

He Gu “Union Valley”

On the dorsum of the first interosseous space of the hand, closer to the index finger than the thumb, at the midpoint of the shaft of the 2nd metacarpal bone, in the belly of the first interosseous dorsalis muscle. The point occurs at the highest part of the muscle bulge when the thumb and index finger are squeezed together. Take LI 4 at the point where the bulge is level with the end of the crease.

Caution when treating pregnant women!

Muscles

- **First dorsal interosseous muscle:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and to flex the metacarpophalangeal joints.
- **First lumbrical muscle:** Flexes the digit at the metacarpophalangeal joint and extends the interphalangeal joint.
- **Adductor pollicis muscle:** Adducts the thumb toward the middle finger.
- **Extensor pollicis longus tendon:** Extends the distal phalanx of the thumb at the metacarpophalangeal joint and the interphalangeal joint.

Clinical Relevance: Complaints of thumb pain and arthritis may develop not only due to joint degeneration, but also myofascial trigger points in the thumb movers (i.e., flexors, extensors, abductors, adductors). Thus, one should employ scientific, medical acupuncture and related techniques (SMARTs) to address soft tissue restriction and trigger point pathology that limits motion from a regional perspective as well as treat pain and tenderness locally.

Nerves

- **Radial nerve (C5-C8):** Supplies all the muscles in the dorsal brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the dorsal forearm to the wrist. The posterior antebrachial cutaneous nerve supplies the skin of the lateral brachium, dorsal antebrachium, and wrist.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. Its four terminal nerves include: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin overlying the carpal bones on the ulnar

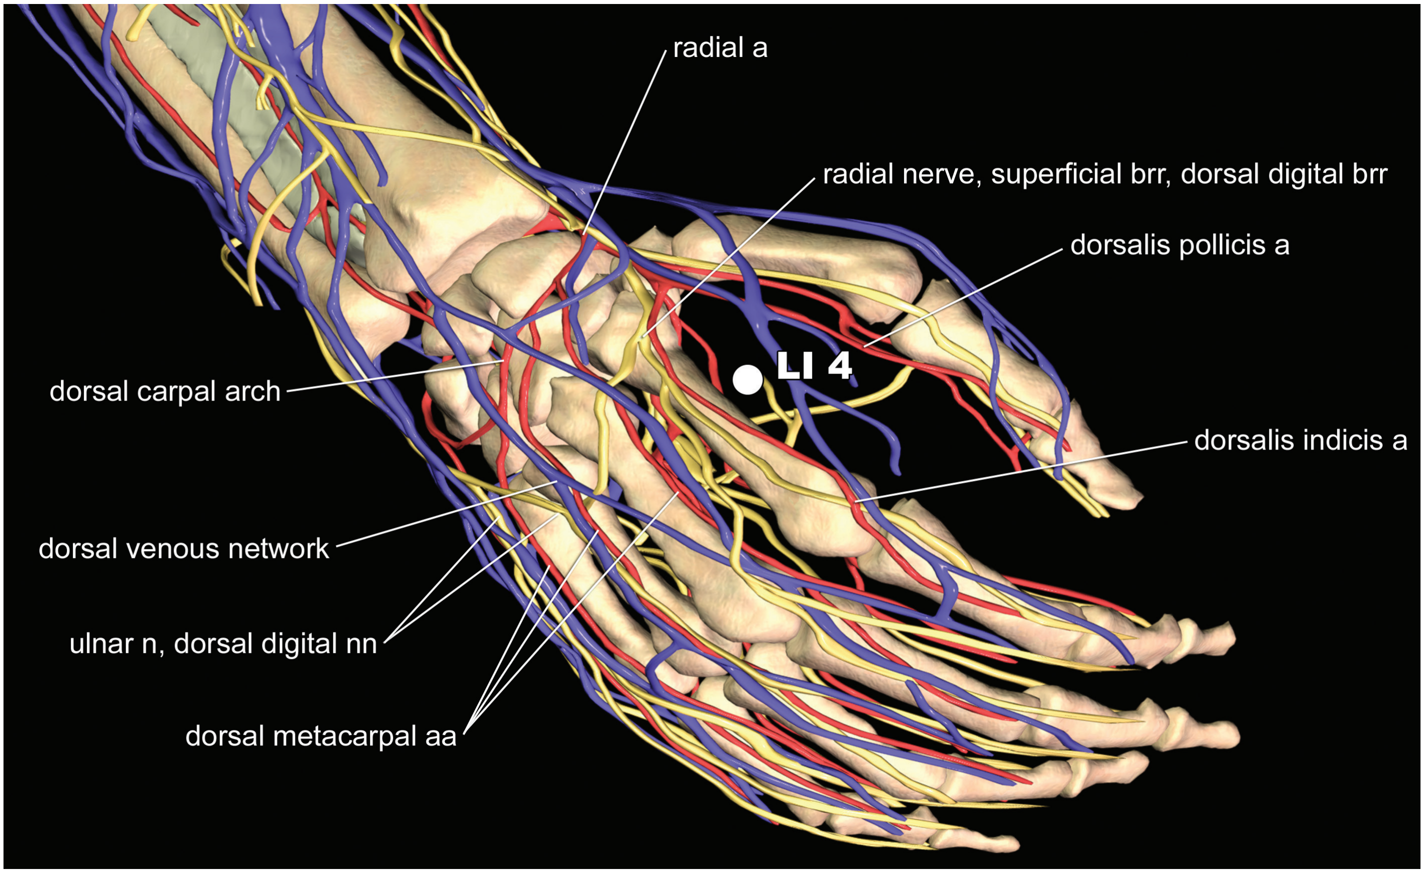

Figure 2-6. LI 4 sits midway along the radial aspect of the shaft of the second metacarpal bone, seen here, and also in the mid-belly of the first dorsal interosseous muscle, as shown in Figure 2-7. The name “Hegu” refers both to a mountain metaphorically formed when approximating the thumb and forefinger. “Hegu” also means “Union Valley”, for the dip that develops by pulling those digits apart.

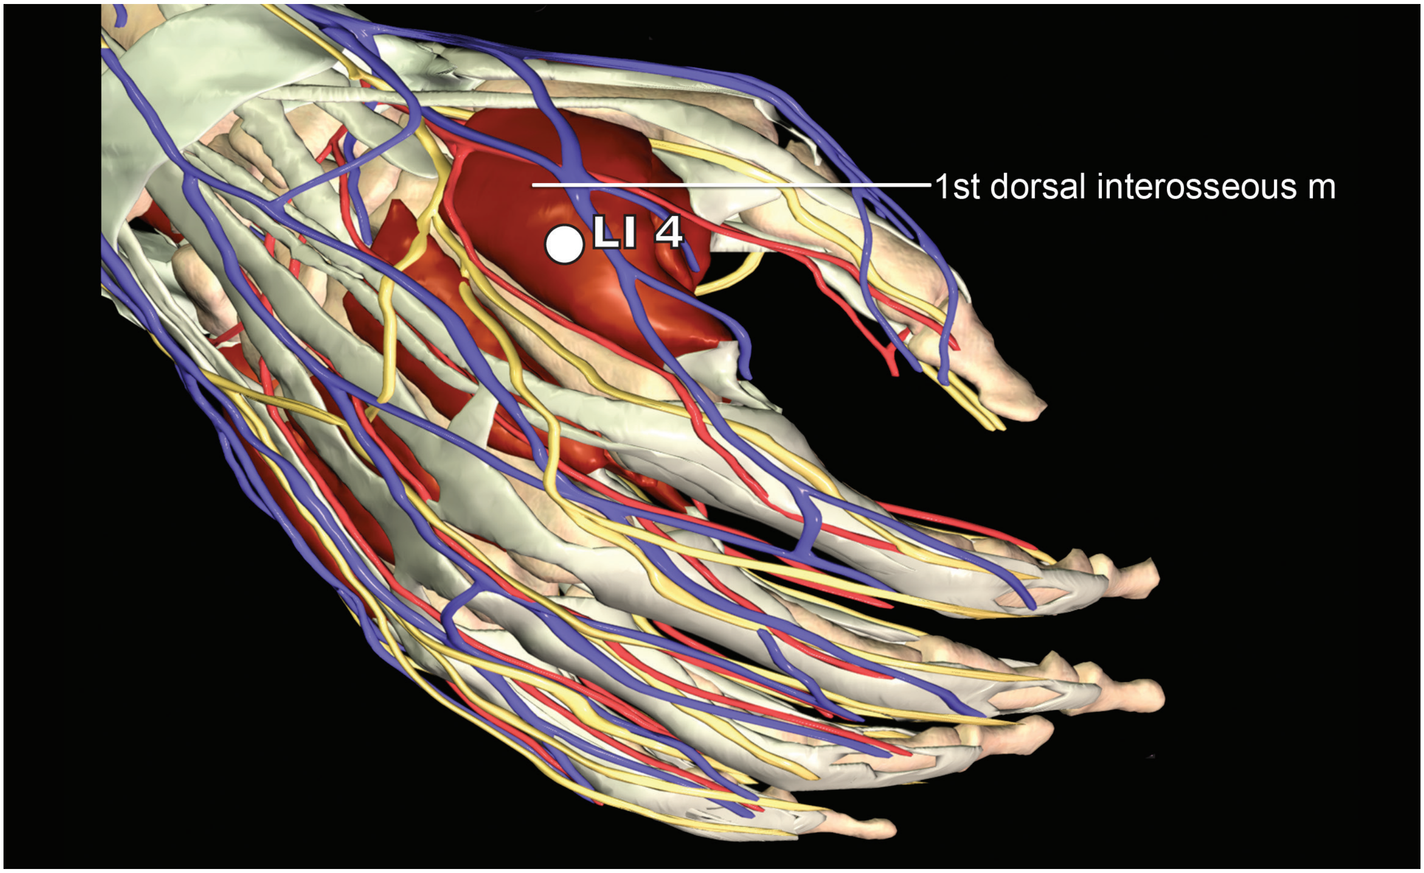

Figure 2-7. The fleshy first dorsal interosseous muscle provides a suitably large target for this highly regarded acupuncture point.

side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle and sensation to the skin of the palmar and distal dorsal aspects of the little finger, the ulnar side of the ring finger, and the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), along with the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

- **Median nerve (C6-T1):** Innervates all thenar muscles except for the adductor pollicis and deep head of the flexor pollicis brevis. Supplies the lumbrical muscles for the 2nd and 3rd digits and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), the radial aspect of the ring finger, and the adjacent palmar areas. Four terminal median nerves include the recurrent (thenar), lateral, medial, and palmar cutaneous branches. The recurrent branch supplies the abductor pollicis brevis, the opponens pollicis, and the superficial head of the flexor pollicis brevis. The lateral branch supplies the 1st lumbrical, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.
- **A note about sympathetic fibers:** The brachial plexus conveys sympathetic and sensory fibers to the lower two-thirds of the brachial artery and all of its branches. Near their destination, these fibers exit the nerve and course through connective tissue to the vessel.
- As described more fully below, distal vessels are more densely innervated than are proximal ones. This, in part, accounts for the stronger autonomic responses associated with distal acupuncture points, especially those at the ends of the channels. Nearly all endpoints land adjacent to the base of the nail of fingers and toes. The Chinese call these"Ting points".
- Specifically, the proximal third of the brachial artery receives its sensory and sympathetic nerves from the radial, median, and musculocutaneous nerves, as does the posterior humeral circumflex artery. The middle third of the brachial artery carries fibers mainly from the medial and musculocutaneous nerves, with some filaments possible from the radial and ulnar nerves. The distal third of the brachial artery is supplied by the median and musculocutaneous nerves, whereas the profunda brachii artery is innervated by fibers from the radial nerve.
- The superior and inferior ulnar collateral arteries receive sensory and sympathetic input from the median nerve.
- As arteries travel toward the fingers, their sympathetic and sensory nerve supply intensifies. That is, more sensory and sympathetic nerve fibers attach to blood vessels per unit area in distal, as opposed to proximal, segments.
- In the forearm, the vasculature's sympathetic and sensory fibers emit from the radial, medial, ulnar nerves, and antebrachial cutaneous nerves.

Specifically:

Radial artery: The proximal third of the radial artery receives input from the median nerve and the lateral antebrachial cutaneous nerves. The radial recurrent artery receives nerve fibers from the deep branch of the radial nerve and the lateral antebrachial cutaneous nerves. Innervation of the mid-portion of the radial artery is thought to be minimal. The distal third of the radial artery receives fibers from the superficial branch of the radial nerve, the lateral antebrachial cutaneous nerves, and possibly the median nerve.

Ulnar artery: The median nerve innervates the upper third of the ulnar artery and the ulnar recurrent artery. The ulnar nerve sends sensory and sympathetic fibers to the mid-portion of the ulnar artery. The ulnar nerve and the medial antebrachial cutaneous nerve supply the distal third of the ulnar artery. The palmar interosseous nerve supplies the palmar interosseous artery. **Arteries of the Hand:** The deep palmar arterial arch is innervated by the deep branch of the ulnar nerve. The superficial palmar arterial arch receives a rich nerve supply from the common digital nerve branches of the ulnar and median nerves. **The proximity of LI 4, HT 8, and PC 8 to the arterial arches of the hand explains, at least in part, their notable autonomic influences.** Each proper digital nerve innervates its accompanying artery comparable to its nerve supply of the skin. **Effects of sympathetic activation:** Sympathetic fibers provide control over both vasoconstriction and vasodilation. The largest arteries of the upper limb (subclavian and axillary) contain few vasomotor fibers. Distal vessels, in contrast, have many vasomotor fibers, as mentioned previously. Increased sympathetic drive from emotions, hemorrhage, or cold provokes vasoconstriction. Sympathetic nerves contain some vasodilator fibers; the fingers carry more vasodilator sympathetic fibers than do the toes. (Parasympathetic cholinergic vasodilator fibers, on the other hand, innervate the arteries of the external genitalia and the pial arteries of the brain.)

- The intimate anatomical relationships between nerves and blood vessels raises the question of which depends on the other during development; i.e., do nerves follow vessels or do vessels follow nerves? A series of experiments reported in 2002 suggested that peripheral nerves secrete vascular endothelial growth factor (VEGF) and thereby outline the pattern of blood vessel branching and arterial differentiation in the skin.[49]

Clinical Relevance: The plurality of nerves congressing near or around LI 4 justify the point's major significance in acupuncture. Every nerve reaching the hand supplies structures located in the vicinity of this point, including the median, radial, ulnar, and sympathetic nerves. This neural diversity reflects the multiplicity of clinical applications, from motor dysfunction to sensory disturbances, as well as from local dysregulation of vasomotor tone to upper body dysautonomia.

Vasoregulation determines how much blood reaches tissues. Periarterial autonomic nervous plexuses alter arterial tone, aided by endothelium-dependent, myogenic, and humoral mechanisms. Defects in hemodynamic homeostasis cause dysfunctional thermoregulation, abnormal blood pressure, and insufficient redirection of flow to the heart and brain under stress states such as hypoxia.[50] VEGF, along with a host of neurotransmitters, neuropeptides, and neurotrophins, orchestrate the regulation of vessel diameter through periarterial nerves.

Vessels

- **Double (superficial and deep) palmar arch:** An arterial and venous network in the palm; each has a superficial and deep loop, formed by the terminating ulnar and radial arteries and veins.
- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Radialis indicis artery:** Arises from the radial artery or the princeps pollicis artery and passes along the radial aspect of the index finger.
- **Dorsalis indicis artery:** Courses along the dorsal radial aspect of the index finger.

Clinical Relevance: Vasculature near LI 4 not only feeds and drains the tissues at the site, but also affects autonomic tone system-wide. Bidirectional signaling between periarterial sympathetic nerve fibers and vascular smooth muscle cells govern local circulation in the hand. Neuromodulation through acupuncture (and activation of a panoply of peripheral, central, and autonomic reflex arcs) thus extends to hemodynamic regulation, opening up an entirely new domain of neuro-effector sites accessible to acupuncture. Disease states characterized by altered neuro-effector function include Raynaud's phenomenon, migraine, orthostatic hypotension, essential hypertension, and congestive heart failure.[51]

Indications and Potential Point Combinations

- **The far-reaching influences of LI 4 on brain function, autonomic activity, cervicothoracic spinal cord reflexes and, secondarily, trigeminal nerve actions create a long list of neuromodulatory changes promoted by this popular acupuncture point, most widely recognized as a treatment for headache.**
- **Headache:** Trigeminal origin (face, teeth, rostral dura) – LI 4, local tender points on the face or scalp, BL 10, GV 20. Cervical origin (occipitofrontalis tension, neck pain in conjunction with head pain): LI 4, BL 10, GB 21, GB 20, GV 20, other tender points in the cervicothoracic region.
- **Dental and oral pain:** LI 4, LU 7, ST 7, CV 24, BL 10.
- **Urticaria and skin problems:** LI 4, LI 11, LI 10, ST 36, GV 14.
- **Nose and throat disorders:** tonsillitis, pharyngitis, epistaxis, rhinitis, sinusitis: LI 4, LU 7, ST 9, CV 23. For frontal sinusitis, add BL 2, GB 14, BL 3. For maxillary sinusitis, add ST 3.
- **Conjunctivitis and eye problems:** LI 4, TH 23, GB 2, BL 2.
- **Delay of menses ("menstrual block"):** LI 4, SP 6, ST 36.
- **Arm and hand pain or restricted movement:** LI4, identify painful or dysfunctional muscles and nerves. Consider Baxie (web spaces between the fingers) to promote nerve communication to the digits. Examine paraspinal points for tenderness or linkage to dysfunction in order to impact relevant spinal cord segments in the cervicothoracic cord. First dorsal interosseous referred pain extends to the radial aspect of the index finger and secondarily the dorsum of the hand and palmar surface of the index finger as well as the palm itself.

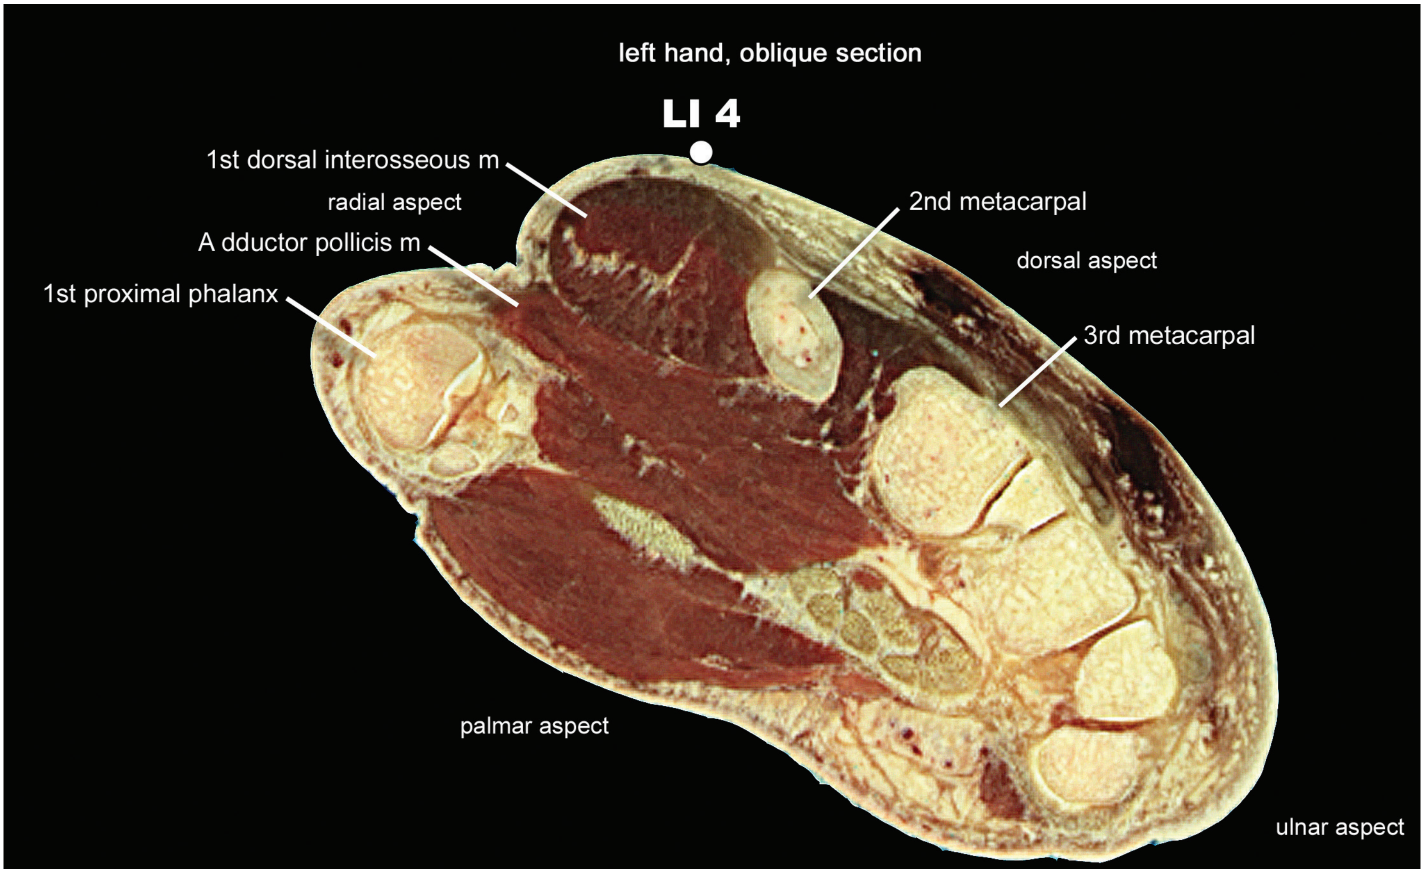

Figure 2-8. This image depicts the roundish nature of the first dorsal interosseous muscle, exhibiting the depth and potential resistance it would deliver to an acupuncture needle.

Evidence-Based Applications

- Both manual acupuncture and low-frequency EA to LI 4, ST 4, ST 7, ST 36, HT 7, SP 6, and KI 5 caused significant increases in local blood flow overlying the parotid gland, suggesting a mechanism for increased salivary flow in **xerostomia** patients.[1]
- Electroacupuncture at LI 4 and SI 3 produce significant **changes in skin temperature** of the hand.[2,3]
- Acupuncture at LI 4 and LI 10 had a **modulatory effect on skin blood flow and heart rate.**[4]
- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with **keratoconjunctivitis sicca** (KCS, or dry eye).[5]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an **increase in the local blood flow in the skin over the parotid gland** in patients with Sjögren's syndrome.[6]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **KCS.**[7]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[8]
- Acupuncture at LI 4 and SP 6 can **shorten** the time interval between estimated date of confinement (EDC) and **actual delivery time**. Helps **support cervical ripening.**[9]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[10]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6 plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome)**.[11]
- Acupuncture at SP 6 and LI 4 was shown to **increase cervical dilatation** without causing changes in human chorionic gonadotropin (HCG).[12]
- Acupuncture at LI 4 reduced the level of expression of COX-2 enzyme in uterine endometrium and myometrium in pregnant and nonpregnant rats. Acupuncture at LI 4 also **reduced uterine motility** in pregnant rats, supporting the suggestion that LI 4 acupuncture inhibits the expression of COX-2 enzyme and may be useful in regulating complicated preterm labor.[13]
- Acupressure at LI 4 and BL 67 significantly **decreased labor pain** during the active phase of the first stage of labor.[14]
- Electroacupuncture at LI 4 and LU 6 **normalized the pattern of leukocytes**, and decreased heart rate.[15]
- Case series reported electroacupuncture at GB 14, SI 18, ST 7, GB 20, and LI 4 was effective treatment for peripheral **facial paralysis.**[16]

- Electroacupuncture at LI 4, LU 7, GV 14, GV 20, the thoracolumbar midline point San Tai and the lumbosacral midline point Baihui (veterinary) demonstrated a reduction of minimum alveolar concentration (MAC) of isoflurane by 16.7% in dogs. Acupuncture-assisted anesthesia thus **potentiated the anesthetic effects of volatile anesthetic agents**.[17]

- LI 4, CV 21, and CV 22 **improved cancer-related breathlessness**.[18]

- Patients suffering from **dysphagia** following stroke who received electroacupuncture from LU 7 to LI 4, and from LU 1/ LI 15 to LI 18 demonstrated significantly greater swallowing function than did patients in the control group.[19]

- Laser acupuncture significantly outperformed sham laser for the treatment of mild to moderate **depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[20]

- Acupuncture stimulation of LI 4 and PC 6 **modulates heart rate variability** differently under fatigue or non-fatigue states.[21]

- Acupuncture at LI 4 **modulates cortical excitability**.[22]

- Pain relief following acupuncture at LI 4 may relate at least in part to decreased regional cerebral blood flow in the putamen.[23]

- Acupuncture at LI 4, LR 3, and PC 6 inhibited sympathetic activation during mental **stress** in advanced heart failure patients.[24]

- Acupuncture at LI 4 and ST 36 activated the hypothalamus and nucleus accumbens. Both of these brain structures are important in mediating acupuncture analgesia. Acupuncture at LI 4 and ST 36 deactivated areas within the limbic system, including the rostral part of the anterior cingulate cortex, amygdala formation, and hippocampal complex. **Limbic deactivation** may play a role in acupuncture analgesia by affecting pain perception – in particular, its affective-cognitive aspect.[25]

- Acupuncture of LI 4 **activated the hypothalamus** (thought to be a key neural substrate mediating acupuncture analgesia), the insula (a cortical region integrating critical functions including visceral sensory, visceral motor, motor association, vestibular, and language activities), the anterior cingulate cortex (possibly involved in mediating the de qi phenomenon), and the cerebellum (interconnected to the hypothalamus by both direct and indirect pathways).[26]

- LI 4 deactivated the nucleus accumbens, amygdala, hippocampus, parahippocampus, hypothalamus, ventral tegmental area, anterior cingulate gyrus, caudate, putamen, temporal pole, and insula, while it caused activation of the somatosensory cortex. This suggests that the complex mechanisms of acupuncture may involve **modulation of activity of subcortical structures**.[27]

- Acupuncture at LI 4 **modified somatosensory evoked potentials**.[28]

- Acupuncture at LI 4, ST 36, SP 6, and SP 9 **reduced discomfort and anxiety** in patients undergoing **colonoscopy**.[29]

- Acupuncture at LI4, LI 11, LR 3, SP 6, ST 25, ST 27, and ST 36 improved well-being and reduced bloating in patients with **irritable bowel syndrome.**[30]

- Transcutaneous electrical nerve stimulation (TENS) at LI 4, LU 10, BL 57, and ST 36 effectively **reduced rectal hypersensitivity** in diarrhea-predominant irritable bowel syndrome.[31]

- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully **treated sleep-related laryngospasm with gastroesophageal reflux**, refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[32]

- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma** patients.[33]

- Acupuncture at LI 4, LI 10, LI 11, LI 15, and TH 5 alleviated pain and improved function in patients with **chronic lateral epicondylitis** (tennis elbow).[34]

- A controlled trial found “aqueous acupuncture” at LI 4 and GB 34 effective for the treatment of **postoperative pain**.[35]

- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders**, prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[36]

- Acupuncture and acupressure may be helpful in reducing **orthodontic post-adjustment pain**. *Journal of Contemporary Dental Practice.* 2005; 6(1):163-167.

- A randomized, placebo-controlled trial suggested that treatment with laser acupuncture at LU 7, LI 4, GB 14, and GB 20 benefits **chronic tension headache**.[37]

- Unilateral acupuncture for advanced **osteoarthritis of the knee** was effective as bilateral acupuncture, using SP 9, SP 10, ST 34, ST 36, and LI 4 on the ipsilateral hand.[38]

- Acupuncture at LI 4 and PC 6 effectively treated **acute postoperative pain** in a patient with pregnancy-induced thrombocytopenia.[39]

- Acupuncture at LI 4 and PC 6 **increased pain threshold and pain tolerance** in the skin over the thyroid.[40]

- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in **prophylaxis of migraine** compared to flunarizine.[41]

- Acupuncture at LR 3, SP 6, LI 4, GB 20, GV 20, and Taiyang outperformed transcutaneous electrical nerve stimulation and laser therapy in **reducing the frequency of migraine**, although all three treatments were effective.[42]

- Acupuncture at LI 4, ST 6, ST 7, and TH 17 was superior to placebo for the prevention of **postoperative dental pain.**[43]

- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 7, ST 6, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[44]

- Acupuncture at LI 4 provided significant short-term pain reduction in **chronic orofacial pain.**[45]

- Electroacupuncture (at ST 29 and TH 5 to LI 4) with manual acupuncture at GV 20 and ST 36 serve as an effective **analgesic during oocyte aspiration**; these analgesic effects equal those of conventional analgesics.[46] Neuropeptide Y (NPY) concentrations in follicular fluid were higher in the electroacupuncture group than in the medication group; NPY may be important for human ovarian steroidogenesis.[47]

- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with chronic **low back pain.**[48]

LI 5

Yang Xi "Yang Ravine"

On the radial side of the wrist, distal to the tip of the styloid process of the radius, in a depression that appears between the tendons of the extensor pollicis longus and brevis muscles, when the thumb is extended, in the anatomical snuff box. Avoid needling the radial artery and the cephalic vein.

Anatomical Snuff Box (Tabatière Anatomique)[1]

- A narrow triangular area associated with the following geometry and structures:
  - Radial side: Extensor pollicis brevis tendon
  - Ulnar side: Extensor pollicis longus tendon
  - Base: Distal edge of the extensor retinaculum
  - Bony floor: Distal radius, scaphoid, trapezium, and proximal end of the first metacarpal bone.
  - Neurovascular contents: Superficial radial nerve branches. Radial artery with a dorsal carpal branch and venae comitantes. Tributaries of the cephalic vein. Connections between the cephalic vein and the venae comitantes of the radial artery may exist within the anatomical snuff box.

Clinical Relevance: Structures inhabiting the anatomical snuff box may suffer iatrogenic injury following surgery (e.g., distal radius fixation) or intravenous catheterization of the distal cephalic vein.[2] Resultant morbidity may respond to acupuncture and related techniques implemented with the goal of reducing inflammation, scarring, and pain while normalizing circulation.

Tendons

- **Extensor pollicis brevis tendon:** Extends the proximal phalanx of the thumb at the carpometacarpal joint.
- **Extensor pollicis longus tendon:** Extends the distal phalanx of the thumb at the metacarpophalangeal joint and the interphalangeal joint.
- **Extensor carpi radialis longus tendon:** Extends and abducts the hand at the wrist.

Clinical Relevance: Iatrogenic injury, overuse syndrome, wrist sprain, tendinitis, weakness in the wrist.

Nerves

- **Posterior interosseous nerve (C7, C8):** The terminal branch of the deep branch of the radial nerve, the posterior interosseous nerve supplies the extensor digitorum, extensor digiti minimi, extensor carpi ulnaris, abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, and extensor indicis muscles.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm

Figure 2-9. This image shows the tendinous borders (the extensor pollicis brevis and longus tendons) of the anatomical snuff box, between which LI 5 nestles. This alley on the dorsal (Yang) surface connotes a stream, hence the name "Yang Ravine".

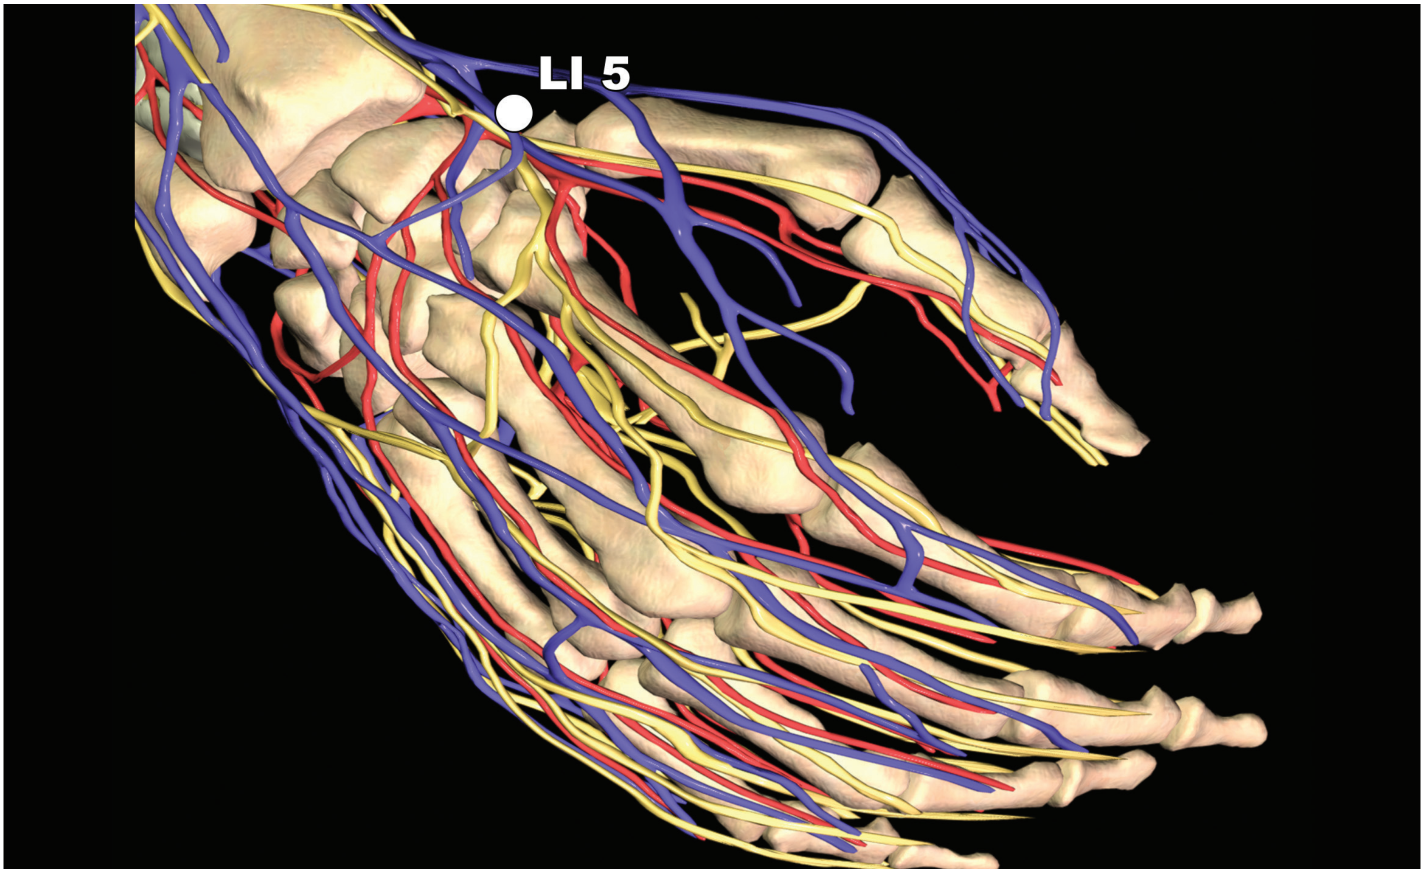

Figure 2-10. The "anatomical snuff box" or "tabatière anatomique" provides a basin that coddles the radial artery and its dorsal carpal branch, tributaries of the cephalic vein, and branches of the superficial radial nerve.

and posterior forearm and wrist.

Clinical Relevance: Iatrogenic injury, neuropathic pain, sensory loss, compressive neuropathy of the superficial branch of the radial nerve by dorsal wrist ganglion or other structures.

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.

Clinical Relevance: Trauma to the radial artery may produce an aneurysm in the anatomical snuff box.[3] Injury to the distal radial artery at this site may lead to digital emboli to the thumb and forefinger.[4]

Indications and Potential Point Combinations

- Extensor pollicis brevis or longus tendinitis, deQuervain's tenosynovitis: LI 5, LI 6, LI 10, LU 7, LU 10.

Evidence-Based Applications

Acupuncture at LI 5 in dogs produced a sympathomimetic effect similar to atropine in dogs with sinus arrhythmia and pulsus alternans.[5]

LI 6

Pian Li "Veering Passageway"

On the radial side of the dorsal antebrachial region, 3 cun proximal to the dorsal wrist crease, or one-fourth the distance from LI 5 to LI 11, along the line that connects them. Divide the distance between LI 5 and LI 11 in half, and then halve the distance between LI 5 and the midpoint.

Muscles and Tendons

- **Extensor carpi radialis longus tendon:** Extends and abducts the hand at the wrist.
- **Extensor carpi radialis brevis tendon:** Extends and abducts the hand at the wrist.
- **Abductor pollicis longus muscle:** Extends the thumb at the carpometacarpal joint and abducts the thumb.

Clinical Relevance: Trigger points referring to the wrist, thumb, or hand; local discomfort.

Nerves

- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.

Clinical Relevance: Altered sensation, loss of extensor function due to radial or other nerve injury or entrapment.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.
- **Local pain or neuralgia:** LI 6, LI 4, LI 10, other local points that

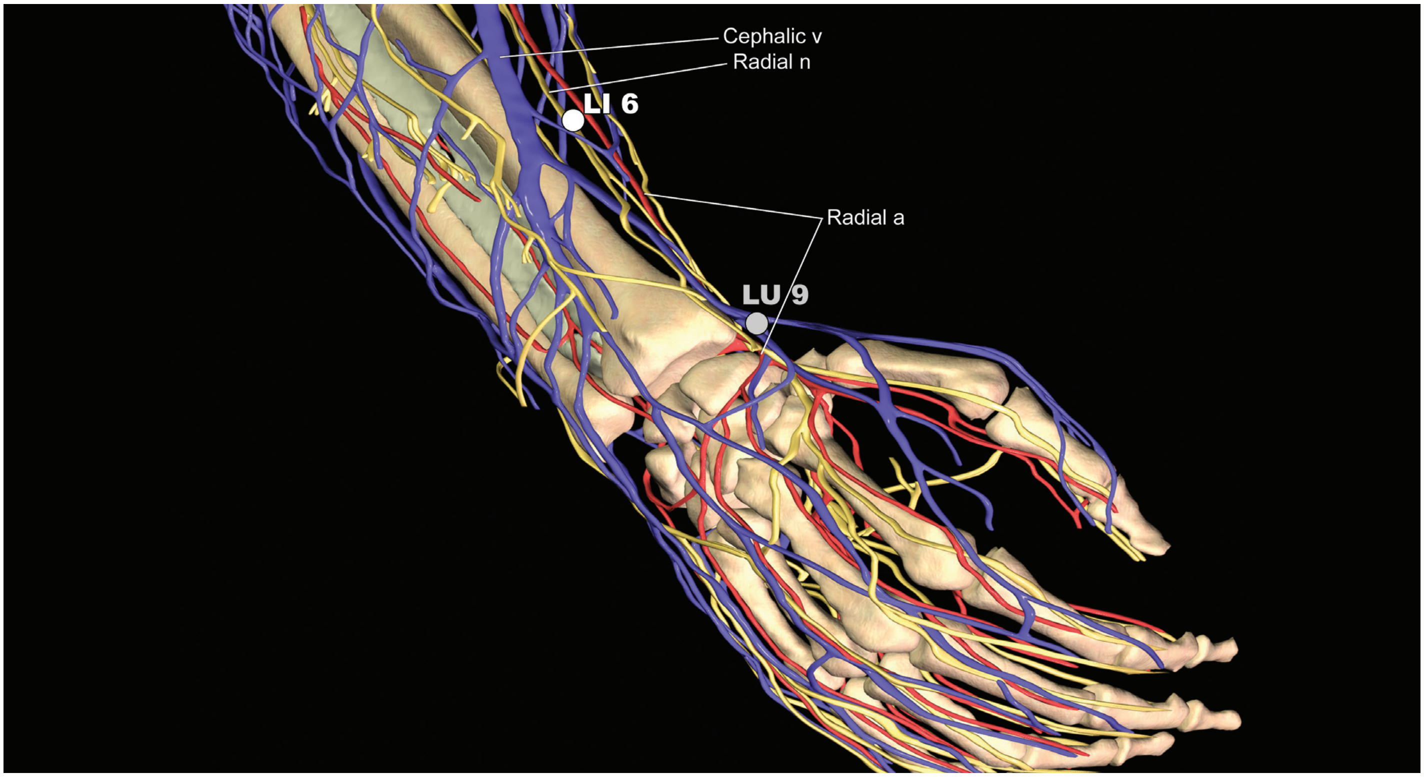

Figure 2-11. This neurovascular view of LI 6 reveals the anatomic underpinning of the Chinese medicine "Luo-Yuan" connection. That is, the Traditional Chinese Medical (TCM) approach to acupuncture asserts that connections exist between certain points on coupled channels. TCM practitioners classify these shunting points as "Luo" and "Yuan" and describe their job as one of shifting "energy" between Yang and Yin "meridians" (a term employed to describe energy pathways) or vice versa. Scientifically based medical acupuncturists, on the other hand, acknowledge the anatomic and neurovascular foundations of acupuncture, in keeping with the original viewpoint by the Chinese that acupuncture pathways constituted blood vessels and associated neural elements. As such, this beautifully portrayed neurovascular connection between LU 9 and LI 6 serves as an example of the anatomical basis of acupuncture. The Chinese name for LI 6 means "Veering Passageway" and refers to the detour taken by these structures toward the thumb.

Figure 2-12. This image depicts the muscles local to LI 6 and highlights the indications of LI 6 for myofascial dysfunction affecting the elbow, antebrachium, and wrist.

exhibit tenderness to palpation or relate neuroanatomically to a neuropathic nerve branch.

Clinical Relevance: Iatrogenic or traumatic vessel injury, bruising.

Indications and Potential Point Combinations

- **Local pain or neuralgia:** LI 6, LI 4, LI 10, other local points that exhibit tenderness to palpation or relate neuroanatomically to a neuropathic nerve branch.

LI 7

Wen Liu "Warm Flow"

On the radial side of the posterior antebrachial region, 5 cun proximal to the dorsal wrist crease, on the line connecting LI 5 and LI 11. Locate by dividing the distance between LI 5 and LI 11 in half; take LI 7 one cun distal to this midpoint.

Muscles and Tendons

- **Extensor carpi radialis longus tendon:** Extends and abducts the hand at the wrist.
- **Extensor carpi radialis brevis muscle:** Extends and abducts the hand at the wrist.
- **Abductor pollicis longus muscle:** Extends the thumb at the carpometacarpal joint and abducts the thumb.

Clinical Relevance: Myofascial dysfunction affecting wrist, hand, and/or thumb function, mobility, and/or strength.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.

Clinical Relevance: Altered sensation, loss of extensor function due to radial or other nerve injury or entrapment.

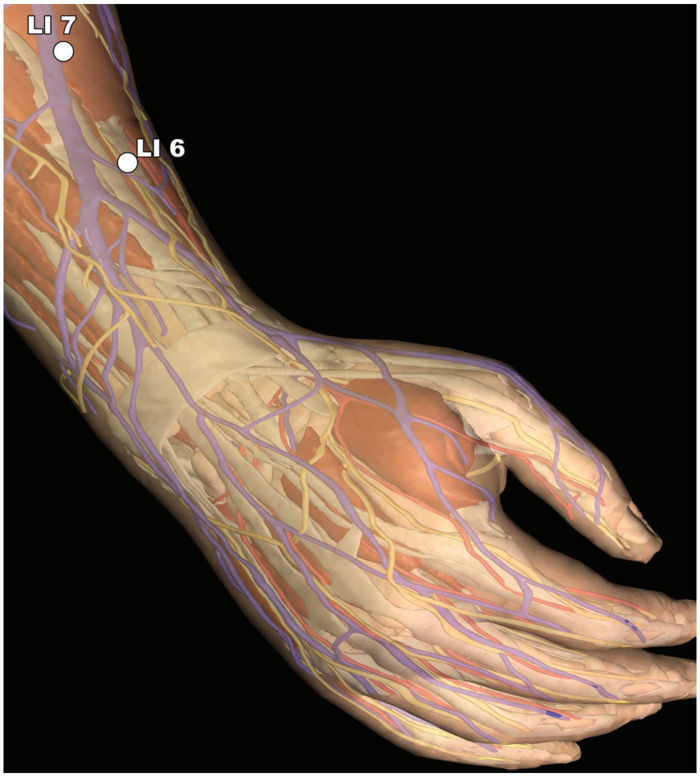

Figure 2-13. The LI 7 point designation as the "Xi-Cleft" point indicates its indications for pain and blockage along the channel. Trigger points located at myotendinous junctions may exhibit tenderness to palpation; these sections of muscles thus serve as fertile territory for myofascial palpation examination.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.
- **Forearm pain:** LI 7 if tender, palpate for trigger points in the proximal extensor carpi radialis longus and brevis muscles, as well as the abductor pollicis longus muscle.

Clinical Relevance: Iatrogenic or traumatic vessel injury, bruising.

Indications and Potential Point Combinations

- **Forearm pain:** LI 7 if tender, palpate for trigger points in the proximal extensor carpi radialis longus and brevis muscles, as well as the abductor pollicis longus muscle.

Figure 2-14. LI 7 sits atop several antebrachial structures that accompany the LI channel and produce the expected physiologic results from acupuncture stimulation. These include the radial nerve and artery, the cephalic vein, and the extensor carpi radialis (ECR) longus tendon and ECR brevis muscle. The cephalic vein ushers through the "Warm Flow" associated with LI 7.

LI 8

Xia Lian "Lower Ridge"

On the radial side of the dorsal antebrachial region, 4 cun distal to LI 11 at the cubital crease, on the line connecting LI 5 and LI 11. Divide the distance between LI 5 and LI 11 into thirds. LI 8 is located between the junction of the middle and proximal thirds.

Muscles and Tendons

- **Extensor carpi radialis longus tendon:** Extends and abducts the hand at the wrist.
- **Extensor carpi radialis brevis muscle:** Extends and abducts the hand at the wrist.
- **Supinator muscle:** Supinates the forearm as it rotates the radius.
- **Brachioradialis muscle:** Flexes the forearm.
- **Abductor pollicis longus muscle:** Extends the thumb at the carpometacarpal joint and abducts the thumb.

Clinical Relevance: Myofascial dysfunction affecting wrist, hand, and/or thumb function, mobility, and/or strength.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.

Clinical Relevance: Altered sensation, loss of extensor function due to radial or other nerve injury or entrapment.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.
- **Extensor carpi radialis brevis myofascial trigger point (with radiating pain to the dorsal wrist and hand):** LI 8, TH 4, TH 3.

Clinical Relevance: Iatrogenic or traumatic vessel injury, bruising.

Indications and Potential Point Combinations

- Extensor carpi radialis brevis myofascial trigger point (with radiating pain to the dorsal wrist and hand): LI 8, TH 4, TH 3.

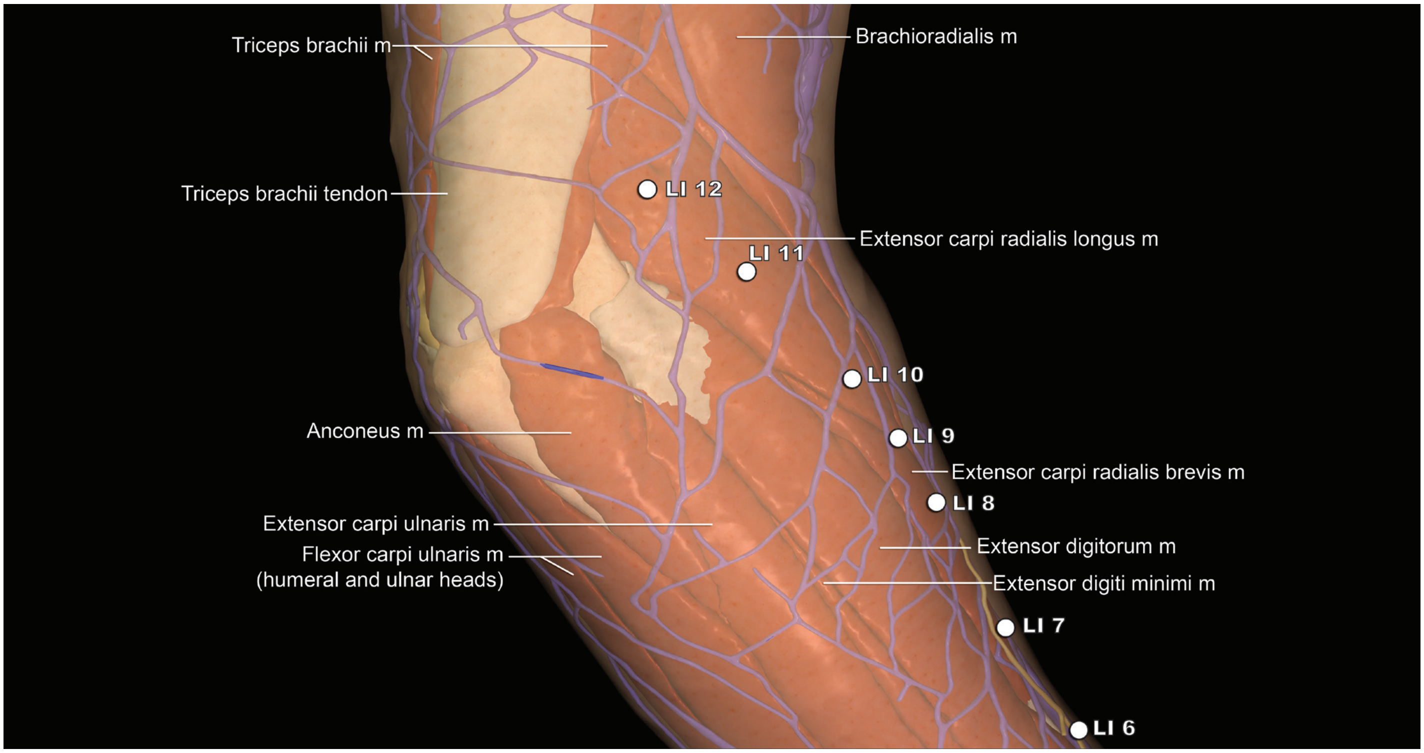

Figure 2-15. The lineup of LI points along the brachioradialis and antebrachial extensors exposes their indications for pain or discomfort involved with actions requiring these muscles' effort. LI 8 huddles on the lower ridge of the extensor bulge over the belly of the extensor carpi radialis brevis muscle.

LI 9

Shang Lian “Upper Ridge”

On the radial side of the dorsal antebrachial region, 3 cun distal to LI 11 at the cubital crease, on the line connecting LI 5 and LI 11. One way to find the point is to divide the distance between LI 5 and LI 11 in half, then bisect the distance between this midpoint and LI 11.

Muscles

- **Extensor carpi radialis longus muscle:** Extends and abducts the hand at the wrist.
- **Extensor carpi radialis brevis muscle:** Extends and abducts the hand at the wrist.
- **Extensor digitorum muscle:** Extends digits II-V at the metacarpophalangeal joints and extends the hand at the wrist.
- **Brachioradialis muscle:** Flexes the forearm.
- **Supinator muscle:** Supinates the forearm as it rotates the radius.
- **Abductor pollicis longus muscle:** Extends the thumb at the carpometacarpal joint and abducts the thumb.

Clinical Relevance: Myofascial dysfunction affecting wrist, hand, and/or thumb function, mobility, and/or strength. Pain, weakness, or restriction with antebrachial supination.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.

Clinical Relevance: Altered sensation, loss of extensor function due to radial or other nerve injury or entrapment.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.
- **Tension or pain in the extensor carpi radialis longus or brevis:** LI 9, LI 8, LI 10, LI 11, and/or LI 6.

Clinical Relevance: Iatrogenic or traumatic vessel injury, bruising.

Indications and Potential Point Combinations

Tension or pain in the extensor carpi radialis longus or brevis: LI 9, LI 8, LI 10, LI 11, and/or LI 6.

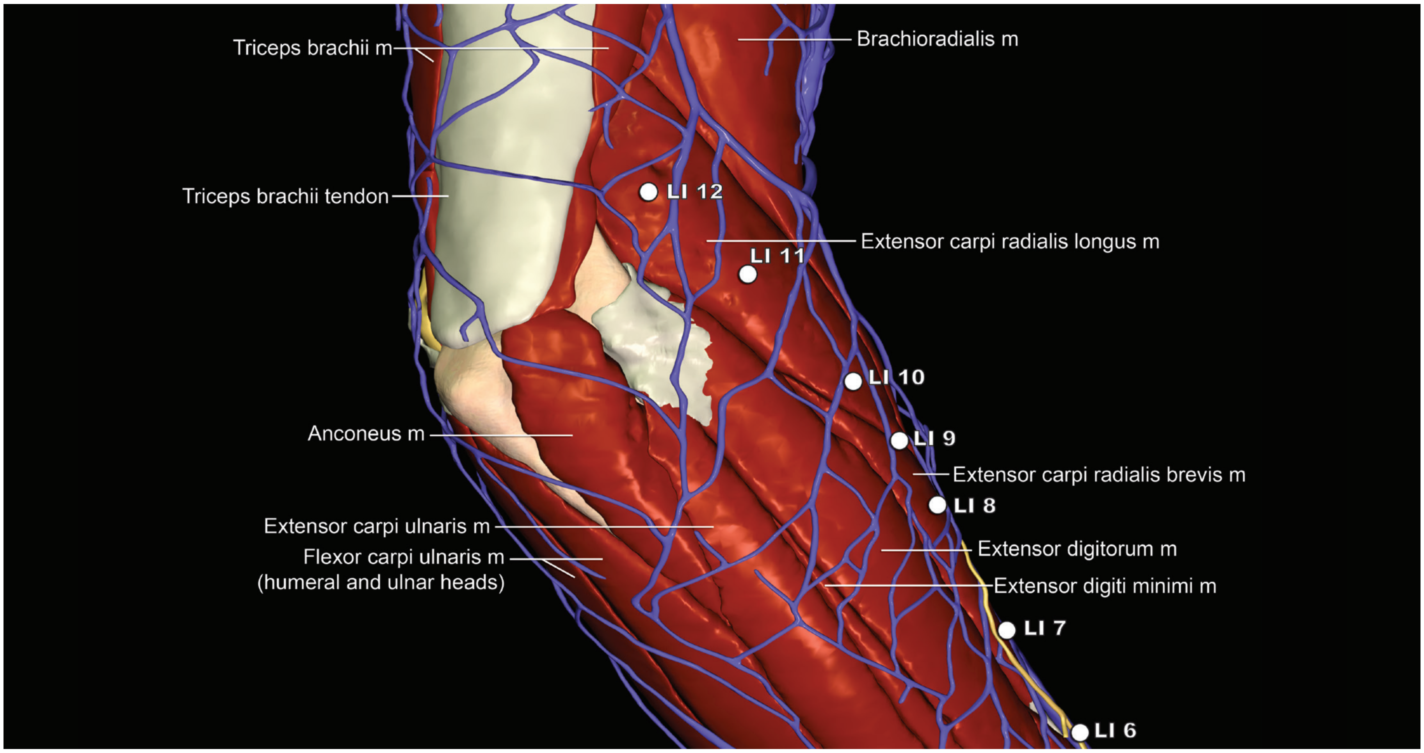

Figure 2-16. LI 9, “Upper Ridge” resides on the ridge of the radius and LI line from hand to elbow. To compare, LI 8, the “Lower Ridge”, lurked below this bony ledge..

LI 10

Shou San Li "Arm Three Li"

On the radial side of the dorsal antebrachial region, 2 cun distal to LI 11, at the cubital crease, on the line connecting LI 5 and LI 11. Usually tender to palpation for its location near the trigger point of the extensor carpi radialis longus muscle.

Muscles

- **Extensor carpi radialis longus muscle:** Extends and abducts the hand at the wrist.
- **Extensor carpi radialis brevis muscle:** Extends and abducts the hand at the wrist.
- **Extensor digitorum muscle:** Extends digits II-V at the metacarpophalangeal joints and extends the hand at the wrist.
- **Brachioradialis muscle:** Flexes the forearm at the elbow.
- **Brachialis muscle:** Flexes the forearm at the elbow.
- **Supinator muscle:** Supinates the forearm as it rotates the radius.

Clinical Relevance: Myofascial dysfunction affecting elbow, wrist, and/or hand, function, mobility, and/or strength. Pain, weakness, or restriction with antebrachial supination, wrist motion, and elbow movement. Lateral epicondylitis, lateral epicondylalgia.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist. Radial nerve compression can produce motor impairments and pain.[1] The signs and symptoms associated with radial tunnel syndrome can produce pain in the lateral elbow and antebrachium, producing symptoms that overlap with lateral epicondylitis. Posterior interosseous nerve compression may additionally cause weakness in the hand.

Clinical Relevance: Altered sensation on the forearm; loss of extensor function due to radial nerve injury or entrapment. Sympathetic neuromodulation in the head, neck, and cranial thorax, pertaining mainly to respiratory conditions and immunologic dysregulation.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist

Figure 2-17. LI 10, "Arm Three Li" resembles ST 36, "Leg Three Li" by occupying a relatively similar position on the extensor surface of the limb amid prominent extensor muscles. This image shows LI 10 in relation to the underlying superficial and deep branches of the radial nerve. It also depicts the continuation of the radial nerve as the posterior interosseous nerve. Compression of these structures generates look-alike nerve compression syndromes (e.g., radial tunnel and posterior interosseous nerve syndrome) with overlapping symptoms that clinicians may confuse with lateral epicondylitis. Accurate diagnosis requires careful palpation, serial examination, and determination of which nerves couple with specific pain and motor impairment.

Figure 2-18. Tension in the forearm extensors, as well as in the supinator muscle, may contribute to chronic lateral elbow pain. This cross section at the level of LI 10 demonstrates the relationship of the point to these structures, as well as the compressible radial nerve, illustrating the value of LI 10 in addressing myofascial restriction for the alleviation of chronic lateral elbow pain.

and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.

- **Radial recurrent artery:** Arises from the radial artery and supplies the brachioradialis and brachialis muscles and the elbow joint. Anastomoses with the radial collateral artery from the profunda brachii artery.
- **Radial artery:** Begins distal to the elbow and ends by forming the deep palmar arch with the deep branch of the ulnar artery.

Clinical Relevance: Iatrogenic or traumatic vessel injury, bruising.

Indications and Potential Point Combinations

- **Gastrointestinal problems:** abdominal pain, dyspepsia, vomiting, diarrhea: LI 10, PC 6, ST 36, CV 12.
- **Thoracic limb pain and weakness:** LI 10, LI 11, LI 4, other points as they relate to neuroanatomically relevant painful or dysfunctional structures in the patient.
- **Tennis elbow (lateral epicondylitis):** LI 10, LI 11, local tender points.

Evidence-Based Applications

- Acupuncture at LI 4, LI 10, LI 11, LI 15, and TH 5 alleviated pain and improved function in patients with **chronic lateral epicondylitis** (tennis elbow).[2]
- Causes a transitory reduction in heart rate, possibly by **reducing sympathetic drive** to the heart.[3]
- Acupuncture at LI 4 and LI 10 had a modulatory effect on skin blood flow and heart rate.[4]
- Moxibustion and point injection at LI 10 and LI 11 helped relieve **lateral epicondylitis** discomfort according to a case series.[5]
- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma** patients.[6]
- Electroacupuncture at LI 10-LI 11, TH 5-LI 4, and direct moxa to each point significantly reduced **spasticity due to stroke**; when applied repeatedly, effects became longer lasting.[7]
- Deep acupuncture at LU 5, TH 5, LI 10, LI 11, and LI 12 produced superior analgesia to superficial needling at these locations for the treatment of lateral epicondylalgia.[8]

LI 11

Qu Chi "Pool at the Bend"

On the lateral side of the elbow, in a depression at the end of the cubital crease when the elbow is close to full flexion, approximately midway between the tendon of the biceps brachii and the lateral epicondyle of the humerus.

Muscles

- **Brachioradialis muscle:** Flexes the forearm at the elbow.
- **Extensor carpi radialis longus muscle:** Extends and abducts the hand at the wrist.
- **Brachialis muscle:** Flexes the forearm at the elbow.

Clinical Relevance: Lateral elbow pain, restricted movement, tension.

Nerves

- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Lateral antebrachial cutaneous nerve (C5, C6):** A continuation of the musculocutaneous nerve, the lateral antebrachial cutaneous nerve supplies a large portion of the skin of the forearm.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.

Clinical Relevance: Altered sensation on the forearm; loss of extensor function due to radial nerve injury or entrapment. Radial nerve injury affecting wrist and hand sensation. Sympathetic neuromodulation in the head, neck, and cranial thorax, pertaining mainly to respiratory conditions and immunologic dysregulation.

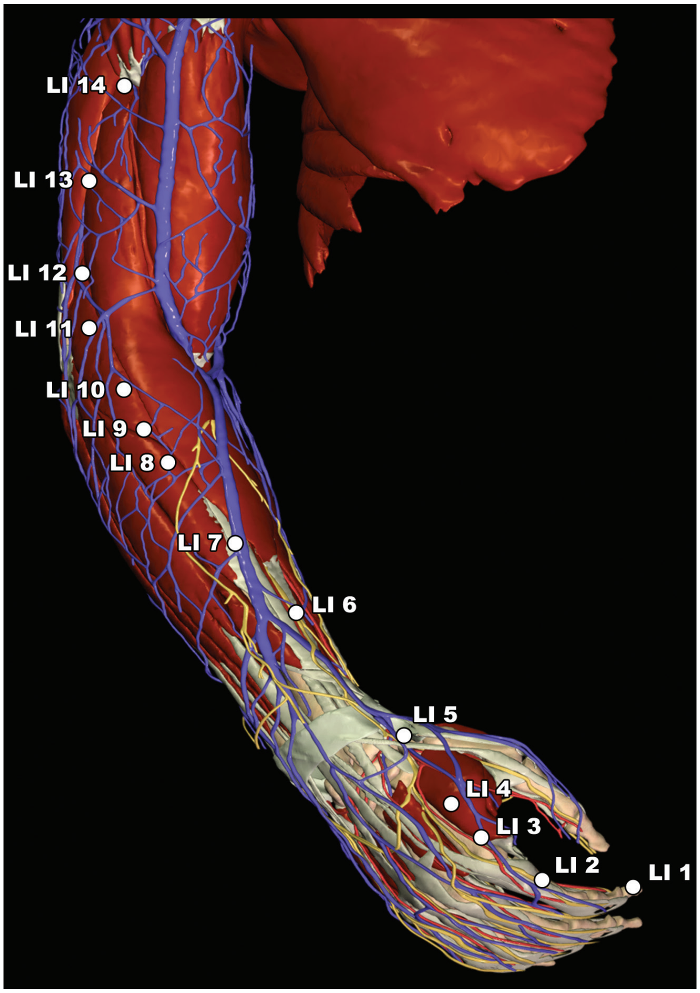

Figure 2-19. The meaty muscle beneath LI 11 beckons dry needling, massage, and laser therapy for lateral elbow pain.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Anterior descending branch of the profunda brachii artery (also known as the radial collateral artery):** Anastomoses with the radial recurrent branch of the radial artery to participate in the arterial anastomoses of the elbow.
- **Radial recurrent artery:** Arises from the radial artery and supplies the brachioradialis and brachialis muscles and the elbow joint. Anastomoses with the radial collateral artery from the profunda brachii artery.

Clinical Relevance: Deep needling of LI 11 accesses the radial nerve as well as the profunda brachii artery. Activation of the nervi vasorum associated with branches of these neurovascular structures would influence autonomic function near and far through sympathetic connections. The proximity of LI 11 to the cephalic vein suggests an application to enhance drainage of an edematous elbow.

Indications and Potential Point Combinations

- **Febrile and viral illnesses:** LI 11, LI 4, GV 14, ST 36, BL 13.
- **Throat problems, tonsillitis, pharyngitis:** LI 11, LI 10, CV 22, ST 36.
- **Radial nerve injury:** LI 11; isolate injury location if possible, needle proximal and distal, as well as cervicothoracic spinal nerves, LI 4, GV 14.
- **Lateral elbow pain:** LI 11, LI 10, trigger points related to elbow pain. Check for trigger points in the triceps brachii.

Figure 2-20. LI 11, "Pool at the Bend", occupies a palpable depression, or pool, at the bend, or elbow. The sink in the tissue appears when the elbow flexes. Notably, the median cubital vein (unlabeled) shows in this cross section as a broad venous ditch just lateral to the biceps brachii muscle, superficial to the bicipital aponeurosis, in the cubital fossa. It connects the basilic and cephalic veins distal to this site.

Evidence-Based Applications

- Acupuncture using magnetic needles at LI 11, ST 40, and LR 3 **lowered endothelin-1**, a potent vasoconstrictive peptide.[1]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an **immunomodulatory** effect for patients with **lichen ruber planus**.[2]
- A case series evaluating acupuncture for **poison ivy contact dermatitis** reported effectiveness with the acupuncture points SP 10, LI 11, and ST 36.[3] These points were also effective in reducing the severity and **preventing recurrences of herpes simplex infections**[4] and in **clearing psoriasis lesions.**[5]
- Treatment for fever using GV 14, GB 20, and LI 11 in patients with **common cold, influenza, acute tonsillitis, or acute bronchitis** helped normalize vital signs and increased T-lymphocytes.[6]
- The four points LI 11, SP 10, SP 6, and ST 36 treat **acute urticaria.**[7]
- Pre-treatment with acupuncture at LI 11 provided a **significant reduction in experimentally-induced (i.e., application of histamine) itch and wheal formation,** compared to acupuncture within the same (C6) dermatome but at a non-acupuncture point, and also to no pre-treatment.[8]
- Effectively relieves **refractory uremic pruritus** in hemodialysis patients.[9,10]
- Repeated acupuncture at ST 36, LI 11, SP 10, and GV 14 significantly decreased leukocyte and lymphocyte values in healthy humans, although cortisol and norepinephrine plasma levels remained unchanged. The mechanism whereby acupuncture affected **leukocyte circulation** was unknown.[11]
- Acupuncture at SP 6 produced a strong vasoconstriction in the ipsilateral leg and a slight vasoconstriction in the contralateral leg with no change in the arms Stimulation of ST 36 produced a superficial vasoconstriction in the skin of both legs but no change in the arms. Stimulation of PC 6 or LI 11 caused **ipsilateral vasoconstriction** in the arms only. This information suggests a topographical representation in the neural segments responsible for the change in sympathetic activity.[12]
- Electroacupuncture (EA) at LI 11 is **antipyretic**, possibly through inhibiting the action of prostaglandin E_2.[13]
- Acupuncture at LI 4, LI 11, LR 3, SP 6, ST 25, ST 27, and ST 36 improved well-being and reduced bloating in patients with **irritable bowel syndrome.**[14]
- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[15]
- Following a series of acupuncture treatments, men with **poor sperm quality** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile

spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[16]

- Electroacupuncture of SI 19 and LI 11 was more effective in **lowering blood pressure** than were other points paired with LI 11.[17] This effect appeared to be related to central opioid and/or noradrenergic mechanisms.[18]
- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[19]
- Acupuncture at LI 4, LI 10, LI 11, LI 15, and TH 5 alleviated pain and improved function in patients with **chronic lateral epicondylitis** (tennis elbow).[20]
- Moxibustion and point injection at LI 10 and LI 11 helped relieve **lateral epicondylitis** discomfort according to a case series.[21]
- Deep acupuncture at LU 5, TH 5, LI 10, LI 11, and LI 12 produced superior analgesia to superficial needling at these locations for the treatment of lateral epicondylalgia.[22]

LI 12

Zhou Liao "Elbow Bone Hole"

With the elbow flexed, LI 12 is one cun proximal to LI 11, at the junction of the lateral supracondylar ridge of the humerus with the lateral epicondyle.

Muscles

- **Triceps brachii muscle:** Extends the forearm at the elbow. Steadies the head of an abducted humerus with the long head.
- **Brachioradialis muscle:** Flexes the forearm at the elbow.
- **Brachialis muscle:** Flexes the forearm at the elbow.

Clinical Relevance: Painful or difficult elbow extension. Tender myofascial trigger points. Lateral arm pain.

Nerves

- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.
- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.

Clinical Relevance: Radial nerve injury, entrapment, or neuropathy, leading to pain, myofascial dysfunction, and possibly neurogenic inflammation in the lateral elbow region.

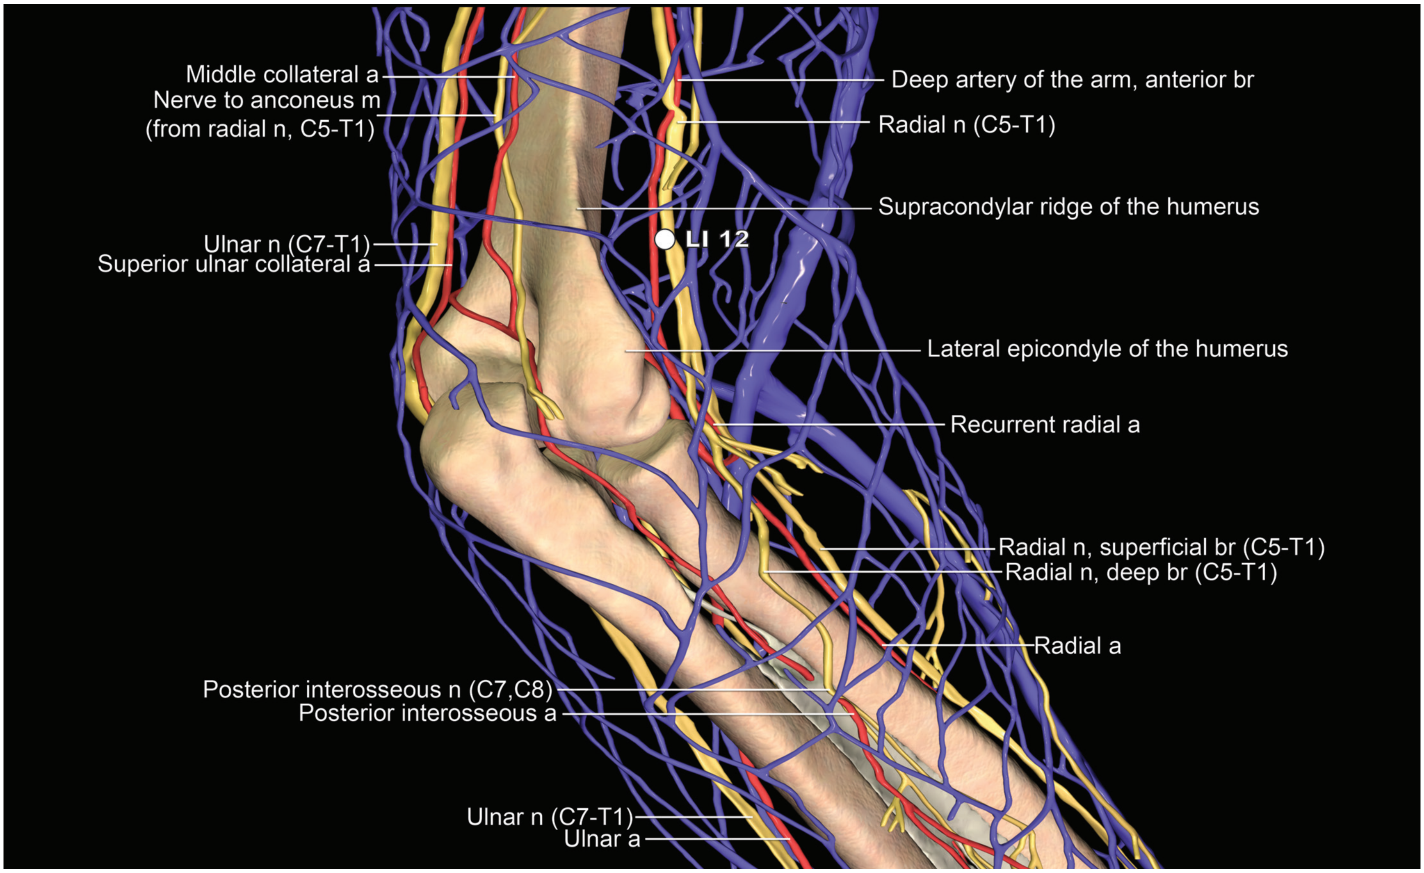
Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes across the anterior elbow to join with the basilic vein. Empties into the axillary vein.
- **Anterior descending branch of the profunda brachii artery (also known as the radial collateral artery):** Anastomoses with the radial recurrent branch of the radial artery to participate in the arterial anastomoses of the elbow.

Clinical Relevance: Local circulatory compromise or altered vasoregulation.

Indications and Potential Point Combinations

- **Pain in the lateral elbow or arm:** Check for brachialis trigger



Middle collateral a

Ulnar a

Figure 2-21. The name for LI 12 of "Elbow Bone-Hole" refers to the palpable depression just proximal to the lateral epicondyle of the humerus, atop the supracondylar ridge.

points,or the lateral portion of the medial head of the triceps brachii muscle. Select LI 12 if tender. Consider adding LI 11, LI 10, PC 3.

- **Radial nerve injury:** Locate site of injury if possible; stimulate proximal and distal to injury; treat myofascial compression associated with injured nerve and neuromodulate locus of impact. Consider LI 12, LI 11, LI 10, LI 4, GV 14, spinal nerve points for lower cervical spinal nerves.

Evidence-Based Applications

- Deep acupuncture at LU 5, TH 5, LI 10, LI 11, and LI 12 produced superior analgesia to superficial needling at these locations for the treatment of lateral epicondylalgia.[1]
- Electroacupuncture at LI 12, TH 5, GB 30, and ST 36 in patients with acute ischemic cerebrovascular disease was associated with significantly increased somatostatin levels in the cerebrospinal fluid and blood and no significant change in pancreatic polypeptide amounts.[2]

LI 13

Shou Wu Liu "Arm Five Li"

On the lateral brachium, 3 cun proximal to LI 11, on the line connecting LI 11 to LI 15, approximately level with where the radial nerve sulcus crosses the lateral margin of the humerus.

Muscles

- **Brachialis muscle:** Flexes the antebrachium at the elbow.

Clinical Relevance: Local trigger point pathology or myofascial dysfunction.

Nerves

- **Inferior lateral brachial cutaneous nerve (C5, C6):** A branch of the radial nerve, this nerve supplies the skin over the inferolateral brachium. It may appear as a branch of the posterior cutaneous nerve of the forearm, also a branch of the radial nerve.
- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Radial nerve (C5-C8):** Supplies all the muscles in the posterior compartment of the brachium. The radial nerve divides into superficial and deep branches near the elbow. The deep branch only supplies muscular and articular branches. The posterior interosseous nerve is a continuation of the deep branch. The superficial branch only supplies cutaneous nerves, providing sensation to the dorsum of the hand and the digits. The posterior cutaneous nerve of the forearm is a branch of the radial nerve that supplies the skin along the posterior aspect of the forearm to the wrist. The posterior antebrachial cutaneous nerve arises from the radial nerve to supply the skin along the lateral arm and posterior forearm and wrist.
- **Musculocutaneous nerve (C5, C6):** Supplies all of the muscles in the anterior, or flexor, compartment of the brachium: the biceps brachii, brachialis, and coracobrachialis muscles. Becomes the lateral cutaneous nerve of the forearm, supplying a large portion of the skin of the antebrachium.

Clinical Relevance: Stiff elbow flexion and/or extension from neuropathic nerves or their spinal nerve roots. Radial nerve injury.

Vessels

- **Cephalic vein:** Ascends from the lateral portion of the dorsal venous network. Courses along the lateral aspect of the wrist and anterolateral forearm and arm. Communicates with the median cubital vein in the anterior elbow, and then passes

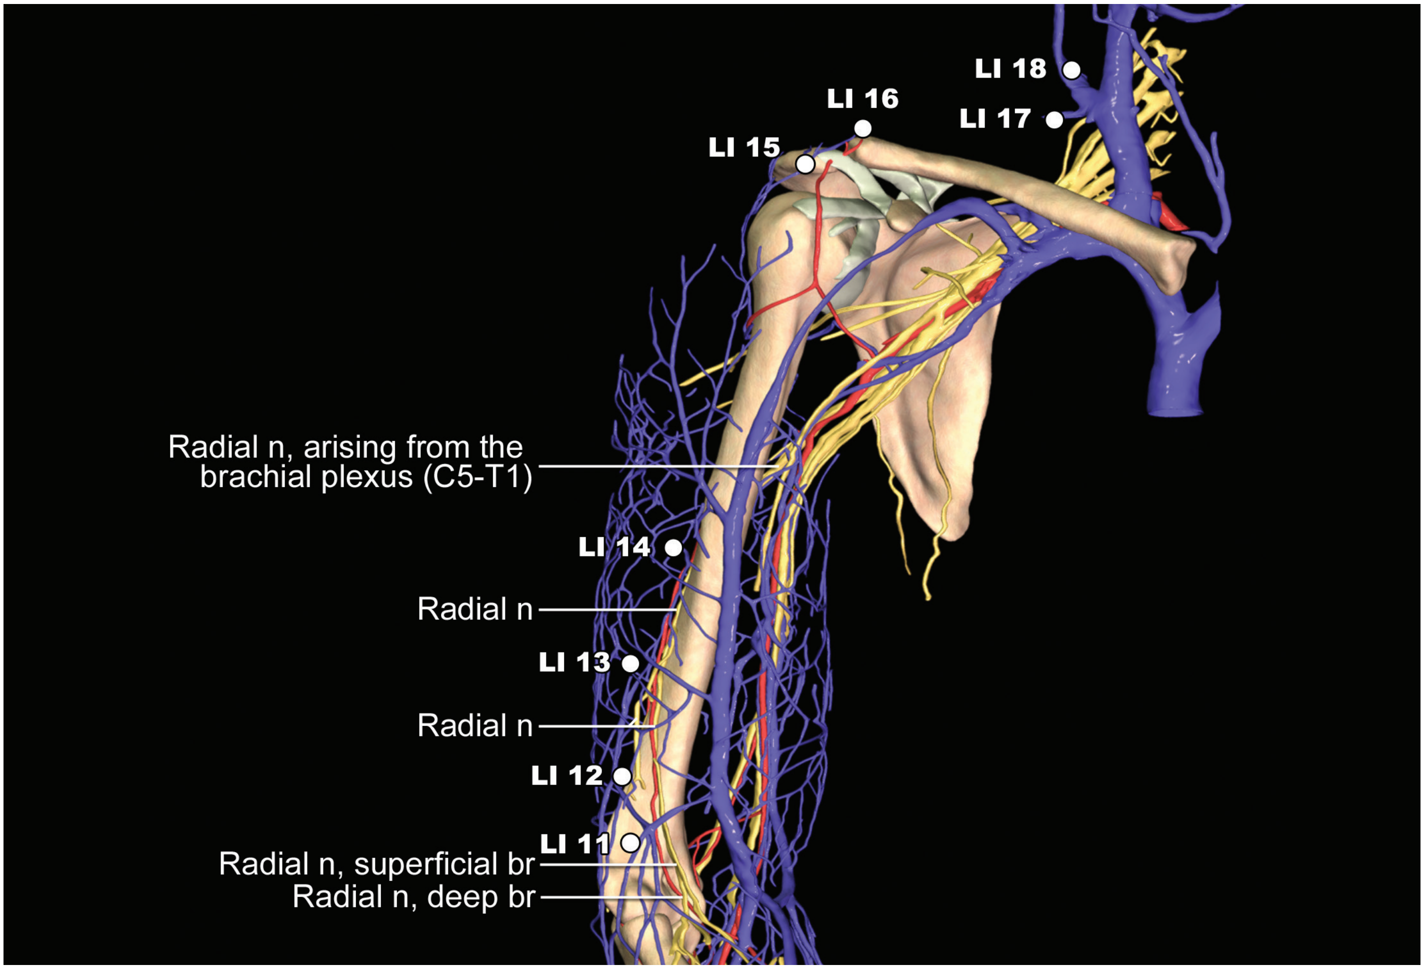

Figure 2-22. LI 13, "Arm Five Li" lands 5 cun proximal to the lateral epicondyle. In this instance, "li" refers to "cun". Note the radial nerve winding around the humerus.

across the anterior elbow to join with the basilic vein. Empties into the axillary vein.

- **Anterior descending branch of the profunda brachii artery (also known as the radial collateral artery):** Anastomoses with the radial recurrent branch of the radial artery to participate in the arterial anastomoses of the elbow.

Clinical Relevance: Supports circulatory supply and drainage to and from the elbow, respectively.

Indications and Potential Point Combinations

- **Lateral arm pain:** Check for trigger points in the brachioradialis, triceps brachii, and brachialis muscles. LI 13 for local pain. Consider LI 12, LI 11.

LI 14

Bi Nao "Upper Arm"

On the lateral brachium, on the anterior margin of the insertion of the deltoid muscle, on the line connecting LI 11 with LI 15. Puncture obliquely upward for deltoid and shoulder problems.

Muscles

- **Deltoid muscle:** Anterior part medially rotates and flexes the arm at the shoulder; middle part abducts the arm; posterior part laterally rotates the arm and extends it.

Clinical Relevance: Deltoid insertion pain, shoulder restriction, local tissue inflammation and trigger points.

Nerves

- **Superior lateral brachial cutaneous nerve (from the axillary nerve):** Supplies the skin over the inferior portion of the deltoid muscle.
- **Axillary nerve (C5, C6):** Supplies the teres minor and deltoid muscles, the skin over the inferior portion of the deltoid (via the superior lateral brachial cutaneous nerve), and the shoulder joint.

Clinical Relevance: Neuropathic nerves due to compression, trauma, or surgery.

Vessels

- **Profunda brachii artery (Deep brachial artery):** This is the largest branch of the brachial artery and accompanies the radial nerve through the radial groove. It divides into anterior and posterior descending branches which take part in the elbow arterial anastomoses.

Clinical Relevance: Consider role of local vasculature (including nervi vasorum) in shoulder recovery from trauma, surgery, adhesive capsulitis, and dislocation.

Indications and Potential Point Combinations

- **Arm pain:** Check for trigger points in the deltoid muscle insertion as well as the lateral border of the lateral head of the triceps brachii muscle.

Figure 2-24. LI 14, "Muscle of the Arm", tucks into the anterior margin of the deltoid muscle insertion. The deltoid attachment incorporates three tendons that form an arch. Fascia investing the deltoid blends with the brachial fascia by way of its confluence with the medial and lateral intermuscular septi. As such, this "delta" joins not only three muscle parts but also three fascial components. (Rispoli DM, Athwal GS, Sperling JW, et al. The anatomy of the deltoid insertion. J Shoulder Elbow Surg. 2009;18:386-390.)

LI 15

Jian Yu "Shoulder Bone"

Inferior to the acromion, on the anterior border of the acromial part of the deltoid muscle, in the anterior of two depressions appearing on either side of the acromion when the arm is abducted 90°.

Bursa

- **Subacromial bursa:** Lies between the coracoacromial arch, the supraspinatus tendon, and the greater tubercle of the humerus.

Clinical Relevance: Subacromial impingement syndrome (a spectrum of pathology that includes subacromial bursitis, rotator cuff tendinopathy, and full-thickness tears of the rotator cuff; may involve features of extrinsic compression and intrinsic degeneration);[3] consider acupuncture and laser therapy for rotator cuff lesions with shoulder stiffness that may arise from local alterations in inflammatory cytokines, leading to myofibroblast recruitment in the subacromial bursa.[4]

Muscles and Tendons

- **Deltoid muscle:** Anterior part medially rotates and flexes the arm; middle part abducts the arm; posterior part laterally rotates the arm and extends it.
- **Supraspinatus tendon:** A rotator cuff muscle, the supraspinatus assists the infraspinatus, teres minor, and subscapularis muscles to hold the head of the humerus in the glenoid cavity of the scapula. Also, assists the deltoid muscle in arm abduction.

Clinical Relevance: Shoulder pain and dysfunction; shoulder joint pathology. Consider acupuncture and related techniques (laser therapy, most notably) for tendon pathology, in light of evidence maintaining the importance of nitric oxide in tendon health and recovery from injury.[5]

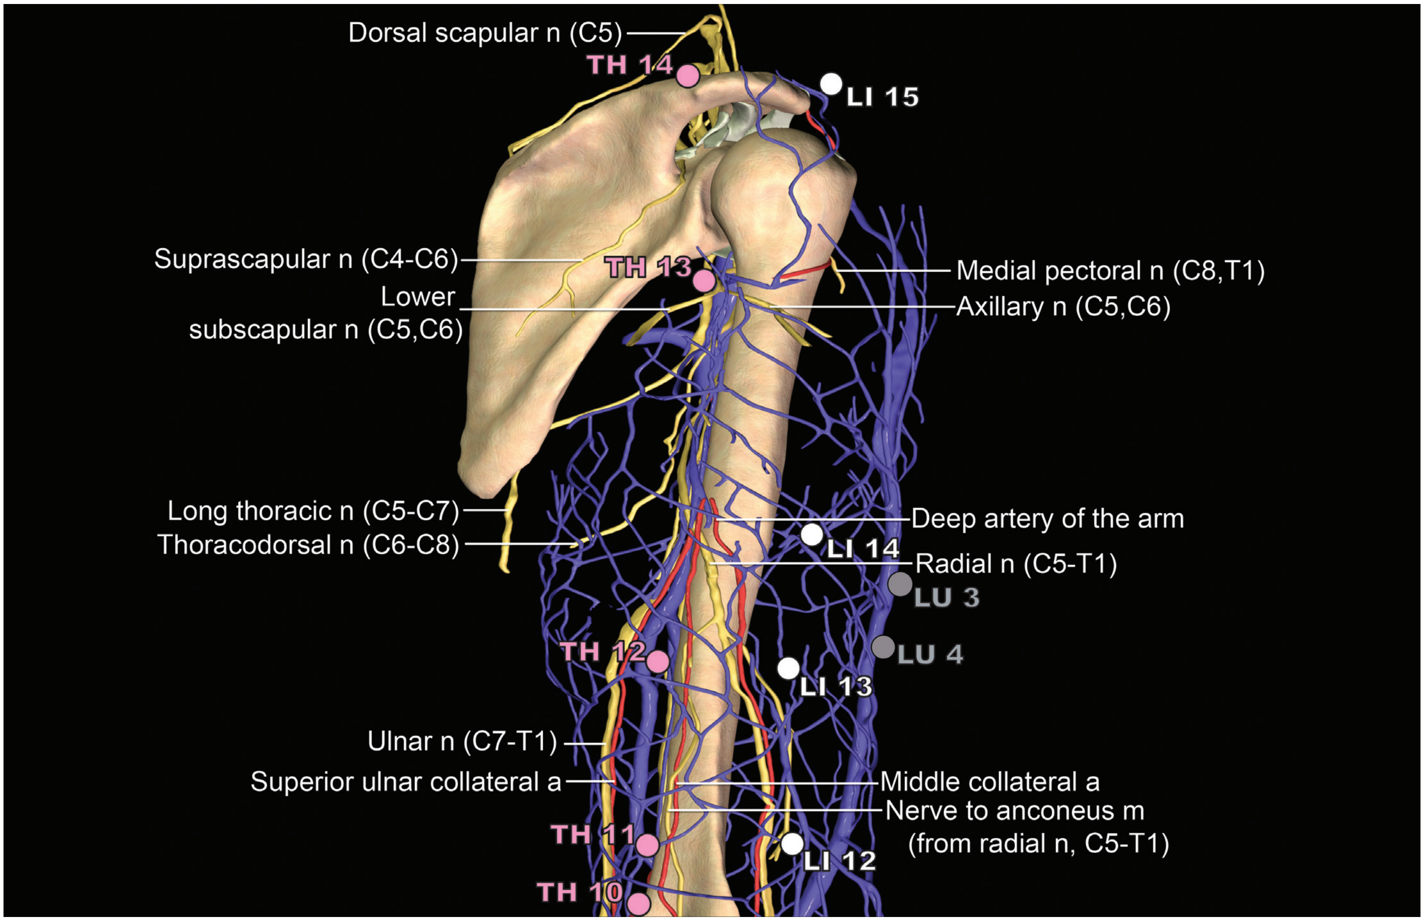
Nerves

- **Supraclavicular nerves (C3, C4):** Supply portions of the skin of the neck and shoulder.
- **Superior lateral brachial cutaneous nerve (from the axillary nerve):** Supplies the skin over the inferior portion of the deltoid muscle.
- **Axillary nerve (C5, C6):** Supplies the teres minor and deltoid muscles, the skin over the inferior portion of the deltoid (via the superior lateral brachial cutaneous nerve), and the shoulder joint.

Clinical Relevance: Supraclavicular or other nerve entrapment, whether by fibrous bands, muscles, or tendons.[6] Painful musculoskeletal conditions lead to central sensitization; this includes patients with shoulder impingement syndrome.[7]

Vessels

- **Thoracoacromial artery:** A short arterial trunk that divides into four branches: the acromial, deltoid, pectoral, and clavicular arteries.



Dorsal scapular n (C5)
TH 14
LI 15
Suprascapular n (C4-C6)

TH 11
LI 12
TH 10

Figure 2-25. LI 15, "Shoulder Bone" often appears with TH 14, "Shoulder Bone Hole" in treatment protocols addressing shoulder joint pain.

Clinical Relevance: Hypovascular zones may promote susceptibility to rupture susceptibility in tendons such as that belonging to the long head of the biceps muscle.[8] Possibly, by supporting circulation through medical acupuncture and related techniques, improved blood flow to tendons will support tissue integrity and strength.

Indications and Potential Point Combinations

- **Anterior shoulder pain:** LI 15 (trigger point in the anterior deltoid region. Palpate for other local trigger points; including the infraspinatus muscle, at or around SI 11 and supraspinatus muscle (SI 12, SI 13) that may refer pain to the anterior shoulder. Coracobrachialis restriction should also be considered and palpated.
- **Shoulder joint pain:** LI 15, TH 14, contributing trigger points.
- **Torticollis:** LI 15, LI 16, LI 18, GB 12, GB 20, SI 17.

Evidence-Based Applications

- Acupuncture at LI 4, LI 10, LI 11, LI 15, and TH 5 alleviated pain and improved function in patients with **chronic lateral epicondylitis (tennis elbow)**.[1]
- Patients suffering from **dysphagia** following stroke who received electroacupuncture from LU 7 to LI 4, and from LU 1/ LI 15 to LI 18 demonstrated significantly greater swallowing function than did patients in the control group.[2]

LI 16

Ju Gu "Great Bone"

On the superior aspect of the shoulder, in the depression that appears between the acromial extremity of the clavicle and the spine of the scapula.

Muscles

- **Trapezius muscle:** The trapezius muscle's superior fibers elevate, middle fibers retract, and inferior fibers depress the scapula.
- **Supraspinatus muscle:** As a rotator cuff muscle, the supraspinatus assists the infraspinatus, teres minor, and subscapularis muscles to hold the head of the humerus in the glenoid cavity of the scapula. Also, assists the deltoid muscle in arm abduction.

Clinical Relevance: Shoulder pain and dysfunction; shoulder joint pathology. Consider acupuncture and related techniques (laser therapy, most notably) for tendon pathology, in light of evidence maintaining the importance of nitric oxide in tendon health and recovery from injury.[1]

Nerves

- **Supraclavicular nerves (C3, C4):** Supply portions of the skin of the neck and shoulder.
- **Spinal accessory nerve (CN XI):** Motor fibers innervate the sternocleidomastoid and trapezius muscles as well as the soft palate and pharynx.
- **Suprascapular nerve (C4, C5, C6):** Arises from the brachial (not the cervical) plexus to supply the supraspinatus and infraspinatus muscles. It also sends branches to the shoulder, or glenohumeral joint.

Clinical Relevance: Supraclavicular or other nerve entrapment, whether by fibrous bands, muscles, or tendons.[2] Painful musculoskeletal conditions lead to central sensitization; this includes patients with shoulder impingement syndrome.[3]

Vessels

- **Suprascapular artery:** Branches off of the thyrocervical trunk to supply the muscles on the posterior aspect of the scapula.

Clinical Relevance: Hypovascular zones may promote

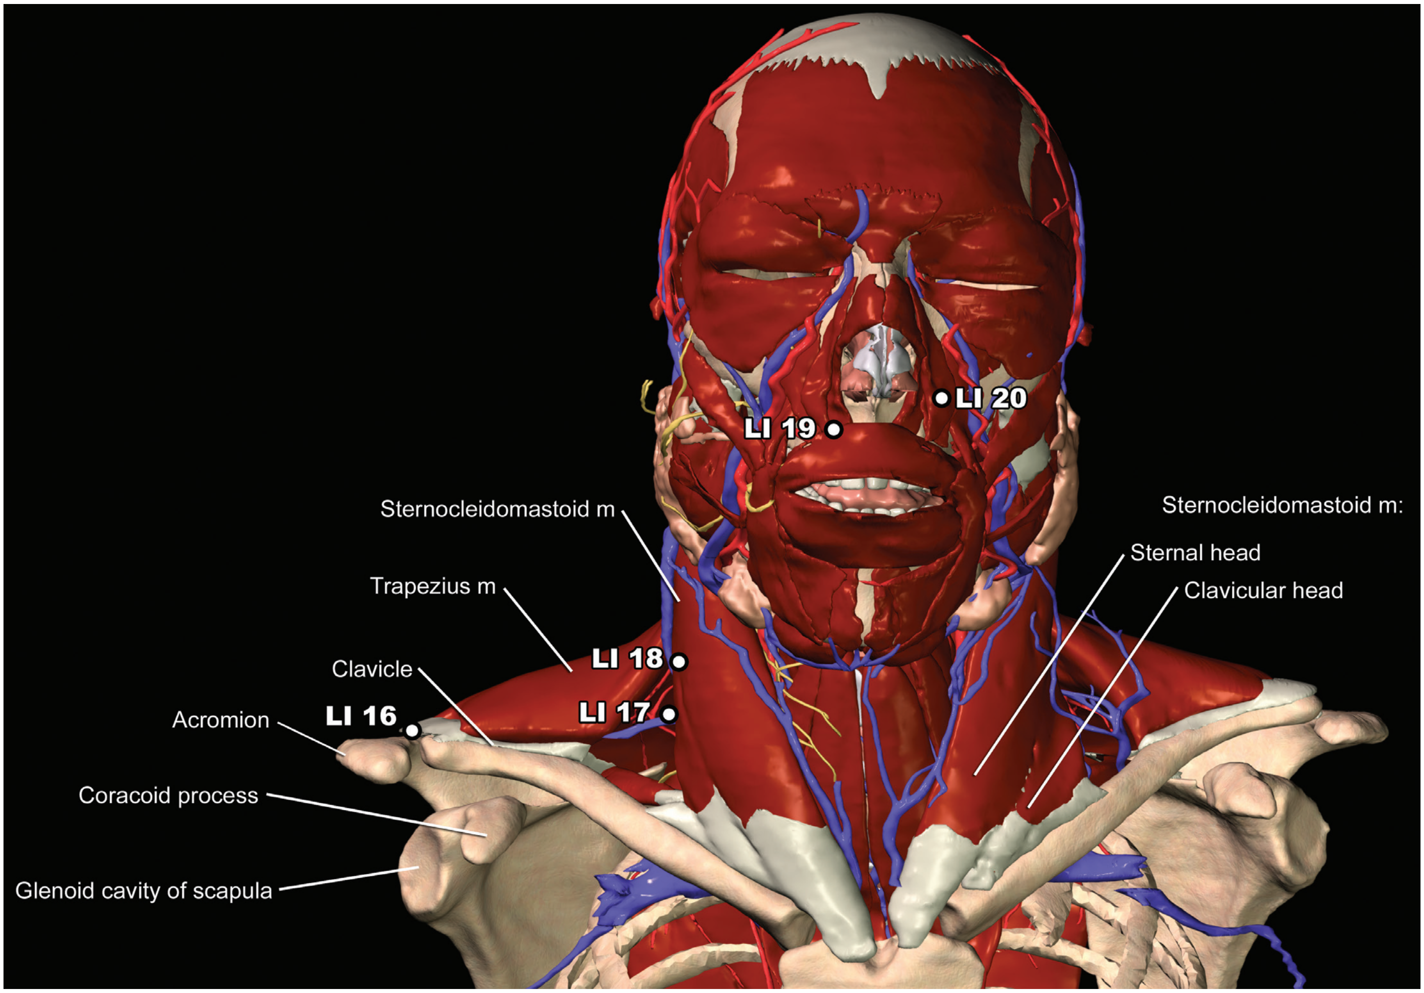

Figure 2-28. The Chinese term for LI 16, "Great Bone" alludes to the acromioclavicular joint as well as the clavicle itself. LI 16 resides in the nook created at the acromial end of the clavicle and the scapular spine, as shown in this image. LI 16 overlooks the supraspinatus outlet, denoted by a space surrounded by the acromoclavicular joint and the acromion along with the coracoacromial arch serving as the roof while the humeral head and glenoid become the floor. Narrowing of the supraspinatus outlet or dysfunction resulting from bearing increased loads can lead to impingement of the supraspinatus tendon. Tendinopathy or tendinitis may ensue

susceptibility to rupture susceptibility in tendons such as that belonging to the long head of the biceps muscle.[4] Possibly, by supporting circulation through medical acupuncture and related techniques, improved blood flow to tendons will support tissue integrity and strength.

Indications and Potential Point Combinations

- **Shoulder pain:** LI 16, isolate trigger points in nearby muscles contributing to the pain (deltoid, trapezius, pectoralis, etc.). Also palpate more distal potential sources of referred pain, including the subscapularis and teres major muscles for trigger points near HT 1. Check latissimus dorsi for trigger points referring to the shoulder.
- **Supraspinatus tendinitis:** LI 16, LI 15, LI 14, SI 12.

LI 17

Tian Ding "Celestial Tripod"

On the anterior margin of the posterior triangle of the neck, on the posterior margin of the sternocleidomastoid muscle, at the midpoint of the line connecting LI 18 to ST 12.

Muscles

- **Platysma muscle:** The platysma muscle moves the corners of the mouth inferiorly, as in expressions of sadness or fright.
- **Sternocleidomastoid (SCM) muscle:** Tilts the head to one side.
- Flexes and rotates the neck to turn the face superiorly to the opposite side.
- **Anterior scalene muscle:** The anterior scalene muscle rotates the neck and flexes it laterally; it also elevates the first rib.
- **Middle scalene muscle:** The middle scalene flexes the neck laterally and raises the first rib during forced inspiration.

Clinical Relevance: Neck pain, restriction, torticollis, vestibular dysfunction, whiplash-associated disorders following motor vehicle accidents.[2]

Nerves

- **Transverse cervical nerve (C2, C3):** Provides sensation to the skin over the anterior triangle of the neck.
- **Cervical branch of the facial nerve (CN VII):** Provides motor innervation to the platysma muscle.
- **Phrenic nerve (C4, with C3 and C5):** Provides sensation to the central part of the diaphragm, as well as the mediastinal pleura and pericardium. Also receives communicating branches from the cervical sympathetic ganglia. Provides sole motor supply to the diaphragm.
- **Brachial plexus (C5-T1):** Superior trunk of the brachial plexus formed by the union of the C5 and C6 roots.
- **Supraclavicular nerves (C3, C4):** Supply portions of the skin of the neck and shoulder.
- **Spinal accessory nerve (CN XI):** Motor fibers innervate the sternocleidomastoid and trapezius muscles as well as the soft palate and pharynx.
- **C2, C3 spinal nerves:** Provides pain sensation and proprioceptive function to the SCM.
- **C5-C8 spinal nerves:** Innervate the middle scalene muscle.
- **Great auricular nerve (C2, C3):** Supplies the skin over the parotid gland, the posterior aspect of the pinna, and a patch of skin spanning from the angle of the mandible to the mastoid process.

Clinical Relevance: Pain, motor disturbances, sensory loss, myofascial restriction, autonomic dysfunction, phrenic nerve injury.

Vessels

- **External jugular vein (EJV):** Most of the blood drained by the EJV arises from the scalp and face.
- **Ascending cervical artery:** Supplies the lateral muscles of the upper neck; is one of the two terminal branches of the thyrocervical trunk (with the inferior thyroid artery).

Clinical Relevance: Caution needling in this highly vascularized zone, rich with autonomic investment. Note the proximity of this point to the external jugular vein.

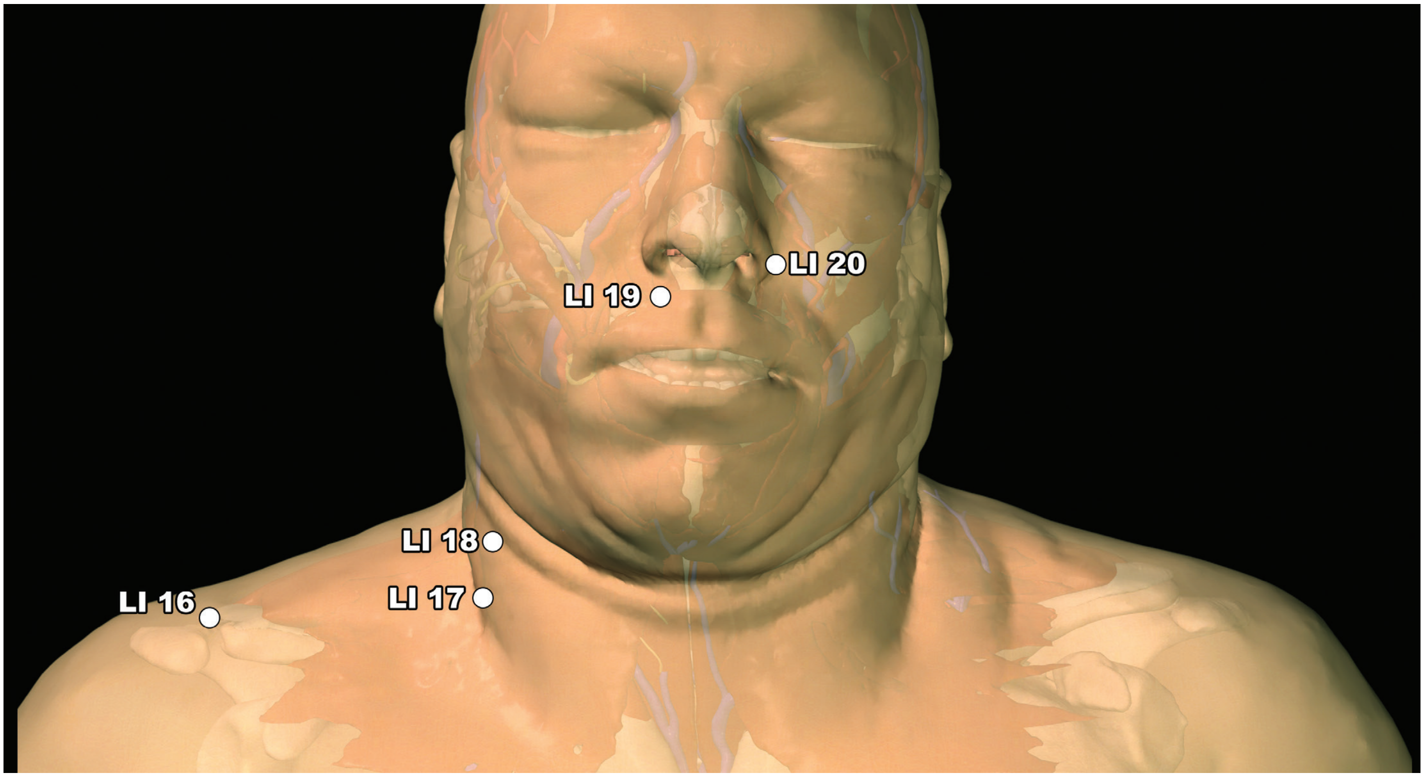

Figure 2-29. The "Celestial Tripod", LI 17, alludes to the location of LI 17 at the base of a cervical triangle that, like the feet of a tripod, support the head, a heavenly structure in Chinese allegory

Indications and Potential Point Combinations

- Neck pain related to trigger points in the scalene and sternocleidomastoid muscles: LI 17.

Evidence-Based Applications

- Point injection of LI 17 was shown in a case series to effectively relieve "obstinate hiccup".[1]

Figure 2-30. This image depicts the close association between LI 17 and the external jugular vein (EJV). The EJV crosses the SCM obliquely to dive into the anteroinferior part of the posterior triangle of the neck to ultimately empty into the subclavian vein. Prior to terminating at the subclavian, the EJV receives the transverse cervical, the anterior jugular, and the suprascapular veins. Although not visible in this view, the great auricular nerve (from C2, C3 ventral rami) ascends diagonally over the SCM as the EJV descends.

Figure 2-33. The cross-section at LI 17 exposes the densely packed neural, vascular, and myofascial structures within reach of an acupuncture needle. While acupuncture needling can influence nociceptive transmission as well as glandular, circulatory, and/or neural control of the head and neck, injudicious needling can cause serious injury.

LI 18

Fu Tu "Protuberance Assistant"

Between the sternal and clavicular heads of the sternocleidomastoid muscle, level with the laryngeal prominence.

Note: Some authors locate the point at the posterior margin of the sternocleidomastoid muscle.

Fascia

- **Carotid sheath:** A facial, tubular structure that contains the internal and common carotid arteries, the internal jugular vein, the vagus nerve, the carotid sinus nerve, sympathetic nerve fibers (i.e., the carotid periarterial plexuses), and deep cervical lymph nodes.

Muscles

- **Platysma muscle:** The platysma muscle moves the corners of the mouth inferiorly, as in expressions of sadness or fright.
- **Sternocleidomastoid (SCM) muscle:** Tilts the head to one side. Flexes and rotates the neck to turn the face superiorly to the opposite side. The SCM participates in the trigemino-cervical reflex, and reflex abnormalities in the trigemino-cervical reflex via brainstem mechanisms appear to participate in the pathogenesis of migraine.[1]

Clinical Relevance: LI 18 lies close to the motor point of the SCM.[6] Thus, while one should always employ caution when stimulating points on the neck, activating LI 18 will likely produce greater contraction strength due to the fact that motor points serve as the locus over the skin where electrical current elicits maximal muscular contraction. Vestibular dysfunction; tinnitus, temporomandibular dysfunction. Neck pain, restriction, torticollis, vestibular dysfunction, whiplash-associated disorders following motor vehicle accidents.[7]

Nerves

- **Transverse cervical nerve (C2, C3):** Provides sensation to the skin over the anterior triangle of the neck.
- **Cervical branch of the facial nerve (CN VII):** Provides motor innervation to the platysma muscle.
- **Supraclavicular nerve (C3, C4):** Supply portions of the skin of the neck and shoulder.
- **Great auricular nerve (C2, C3):** Supplies the skin over the parotid gland, the posterior part of the auricle, and the skin between the mandible and the mastoid process.
- **Spinal accessory nerve (CN XI):** Motor fibers innervate the sternocleidomastoid and trapezius muscles as well as the soft palate and pharynx.
- **Ansa cervicalis (C1-C3; possibly also the vagus nerve (CN X) in some cases):**[2] Supplies the infrahyoid muscles of the anterior cervical triangle.
- **Carotid sinus nerve (CN IX):** Provides sensation to the carotid sinus and carotid body.
- **Vagus nerve (CN X):** Sensation from the inferior pharynx, the larynx, and thoracoabdominal viscera; taste from the root of the tongue and epiglottis; motor and proprioception to the soft palate, pharynx, intrinsic laryngeal muscles, and the palatoglossus; parasympathetic function to the thoracoabdominal organs.

Clinical Relevance: Laryngeal dysfunction; autonomic dysregulation or deafferentation; dysphagia; hemodynamic instability (caution: could cause by stimulating this site); local pain,

myofascial restriction, or sensory disturbances. Vestibular dysfunction; tinnitus, temporomandibular dysfunction.

Vessels

- **External jugular vein (EJV):** Most of the blood drained by the EJV arises from the scalp and face.
- **Internal jugular vein (IJV):** The main venous structure of the neck. Originates from the sigmoid (dural venous) sinus and travels in the carotid sheath as it descends through the neck region. It unites with the subclavian vein at the level of T1 to form the brachiocephalic vein.
- **Common carotid artery:** Divides into the internal and external carotid arteries. The internal carotid artery has no branches in the neck and provides the main blood supply to the brain and structures within the orbits. The external carotid artery supplies structures mainly external to the skull, except for the middle meningeal artery.
- **Ascending cervical artery:** Supplies the lateral muscles of the upper neck; is one of the two terminal branches of the thyrocervical trunk (with the inferior thyroid artery).

Clinical Relevance: Caution needling in this highly vascularized zone, rich with autonomic investment. Note the proximity of this point to the major vessels of the neck.

Indications and Potential Point Combinations

- **Inflammation, edema, or nodules on vocal cords:** LI 18, CV 23, CV 22, ST 36, LI 4.
- **Laryngitis, and post-extubation inflammation and edema of larynx:** LI 18, CV 22.
- **Sore throat, tonsillitis, cough, sputum in the throat:** LI 18, LI 11, LI 4, LU 7.
- **Restricted range of motion of the neck based on local trigger points (scalenes, sternocleidomastoid muscle):** LI 18, LI 17, BL 10, GB 20, GB 21.

Evidence-Based Applications

- Case series illustrated applications for **shoulder and back pain, arm pain, and pharyngitis/laryngitis.**[3]
- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary • Sjögren's syndrome, irradiation, or other causes.[4]
- Patients suffering from **dysphagia** following stroke who received electroacupuncture from LU 7 to LI 4, and from LU 1/ LI 15 to LI 18 demonstrated significantly greater swallowing function than did patients in the control group.[5]

LI 19

He Liao "Grain Bone Hole"

On the upper lip, directly below the lateral margin of the nostril, level with GV 26. (GV 26 lives at the junction of the upper third with the lower two-thirds of the philtrum, along the midline.)

Muscles

- **Levator labii superioris muscle:** Elevates the upper lip and dilates the naris.[1]
- **Orbicularis oris muscle:** Oral sphincter.

Clinical Relevance: Muscles that move the mouth (and eyes) receive much attention from plastic surgeons for cosmetic procedures. Acupressure, acupuncture, and laser therapy "face lifts" might include focus on LI 19 to address the linear folds in the midfacial region and nasolabial crease, common signs of aging. Researchers in Asia have considered local points around the mouth for the treatment of "gummy smile", i.e., excessive display of gingival tissue on smiling, with relaxation of the levator labii superioris muscle with relaxing neuromodulatory input, given that botulinum toxin has shown improvements when injected into this region.[2]

Nerves

- **Infraorbital nerve (CN V$_2$):** Provides sensation to the skin of the cheek and lower lid, the side of the nose, inferior septum, and upper lip. Also provides sensation to the upper premolar incisors and canine teeth as well as the mucosae of the maxillary sinus and upper lip.
- **Buccal branches of facial nerve (CN VII):** Supplies the buccinator muscle, upper parts of the orbicularis oris, and inferior fibers of the levator labii superioris muscles.

Clinical Relevance: Facial nerve injury, local sensory loss, dental pain of the upper arcade.

Vessels

- **Infraorbital artery:** Arises from the maxillary artery to supply the face and part of the orbit.
- **Superior labial artery:** Arises from the facial artery and runs medially in the upper lip.

Clinical Relevance: Richly supplied with sympathetic and sensory fibers, locales such as LI 19, LI 20, and nearby GV 26 confer local and generalized sympathomimetic effects on the individual. Results include clearing of the nasal passages and cardiopulmonary arousal.

Indications and Potential Point Combinations

- **Facial paralysis affecting the buccal branch of the facial nerve:** LI 19, ST 4, TH 17.
- **Toothache, upper arcade:** LI 19, ST 2, LI 4, LU 7.

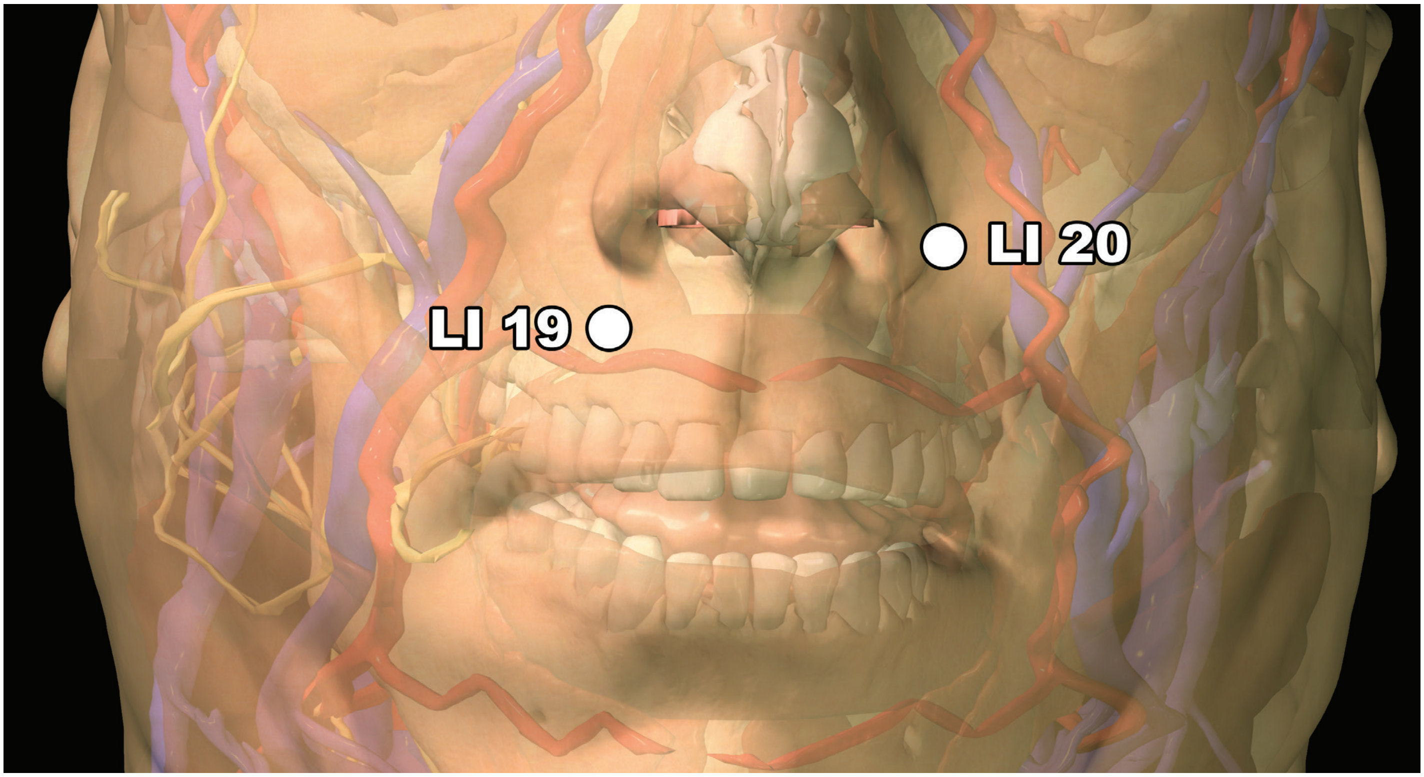

Figure 2-36. LI 19, "Grain Bone-Hole" lines up with the space behind the canine tooth where a space exists, about the size of a grain of rice. The infraorbital nerve (a branch of the trigeminal nerve) and the buccal branch of the facial nerve supply this area with sensory and motor functions, respectively. This justifies the indications of LI 19 for pain in local structures including the teeth, facial nerve injury, and nasal congestion.

Figure 2-37. LI 19, like GV 26, lies at the junction of the upper third and the lower two thirds of the philtrum, interacting with several muscles of facial expression. Note the muscle medial to the levator labii superioris alaeque nasi, just lateral to LI 19. This unlabeled structure is the levator labii superioris muscle.

LI 20

Ying Xiang "Welcome Fragrance"

In the nasolabial groove, at the level of the midpoint of the lateral border of the ala nasi.

Note: This is the only channel that crosses the midline. Here, LI decussates under the nose between LI 19 and LI 20. As such, LI 20 ends on the side of the body opposite from where it began at LI 1.

Muscles

- **Levator labii superioris muscle:** Elevates the upper lip and dilates the naris.
- **Levator labii superioris alaeque nasi (LLSAN) muscle:** Elevates the upper lip and dilates the naris.

Clinical Relevance: One can classify the muscles of facial expression according to which orifices of the face they close (as sphincters) or open (as dilators); in this case, the LLSAN is a naris dilator. Whether the muscles' role in opening and shutting entryways to the eye and tongue outweighs their value in conveying facial expression remains a matter of debate.[2] Certain primate species possess a "highly graded and intricate facial expression repertoire" that depends heavily on facial muscle movement.[3] Comparisons of human with other primate anatomy yield insights into the form and function of facial musculature from a phylogenetic perspective.[4]

Nerves

- **Infraorbital nerve (CN V$_2$):** Provides sensation to the skin of the cheek and lower lid, the side of the nose, inferior septum, and upper lip. Also provides sensation to the upper premolar incisors and canine teeth as well as the mucosae of the maxillary sinus and upper lip.
- **Buccal branches of facial nerve (CN VII):** Supplies the buccinator muscle, upper parts of the orbicularis oris, and inferior fibers of the levator labii superioris muscles.

Clinical Relevance: Nasal congestion, sinusitis.

Vessels

- **Infraorbital artery:** Arises from the maxillary artery to supply the face and part of the orbit.
- **Superior labial artery:** Arises from the facial artery and runs medially in the upper lip.

Clinical Relevance: Richly supplied with sympathetic and sensory fibers, locales such as LI 19, LI 20, and nearby GV 26 confer local and generalized sympathomimetic effects on the individual. Results include clearing of the nasal passages and sinuses; dental pain.

Indications and Potential Point Combinations

- **Rhinitis, maxillary sinusitis:** LI 20, ST 3, Yintang (GV 24.5).
- **Epistaxis:** LI 20, LI 19, GV 23.
- **Anosmia:** LI 20, GV 23, GV 24.5, GV 20.

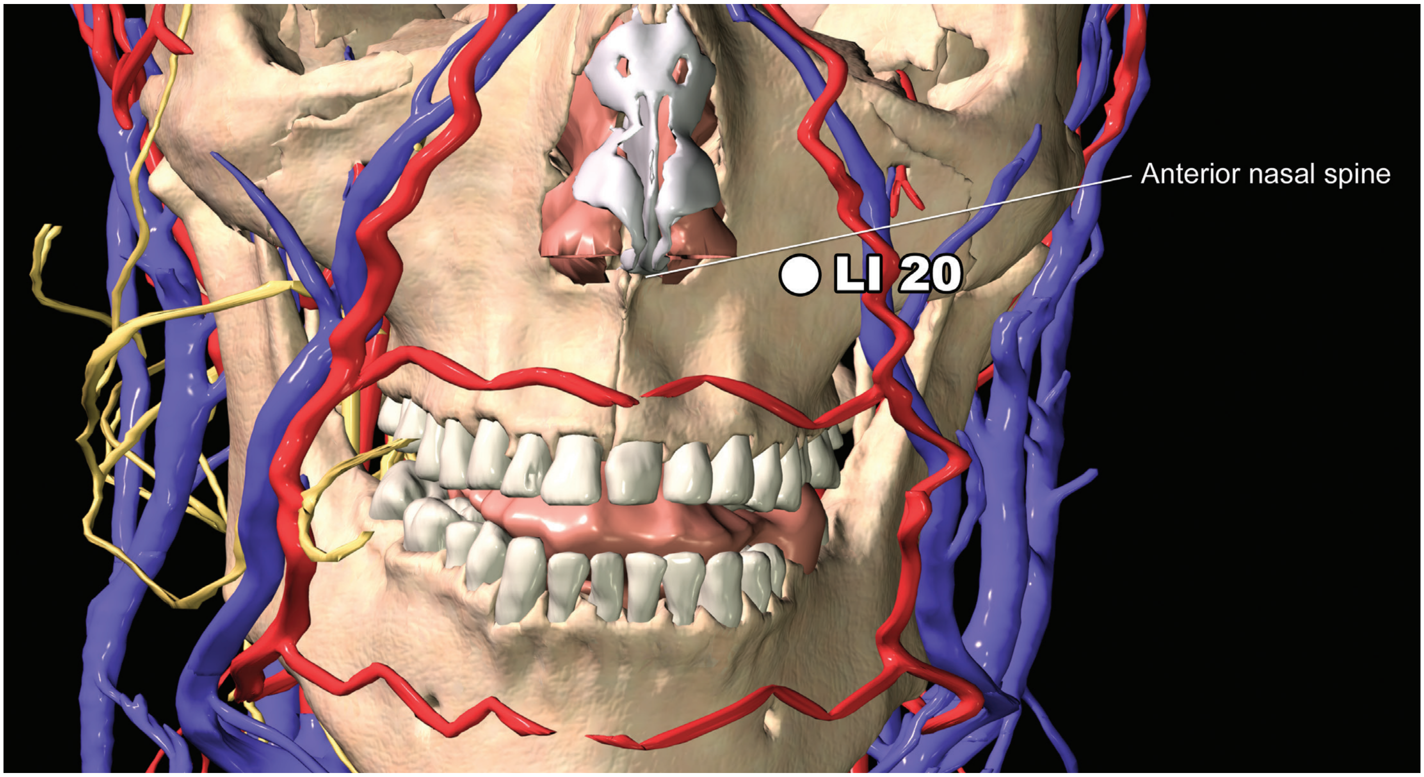

Figure 2-38. LI 20, "Welcome Fragrance", improves the sense of smell by clearing nasal passages, presumably through activation of trigeminal nerve sensory reflexes and local autonomic neuromodulation.

Channel 3:: The Stomach (ST)

The Stomach (ST) channel comprises two branches. The shorter one drops down below the pupil, then swoops around the masseter muscle and swings up the temple. The longer branch descends from neck to clavicle, and straight down the thorax and abdomen, paralleling the Spleen, Kidney, and Conception Vessel lines. From groin to foot, the ST channel covers the anterolateral pelvic limb to end at ST 45 on the lateral aspect of toe number two.

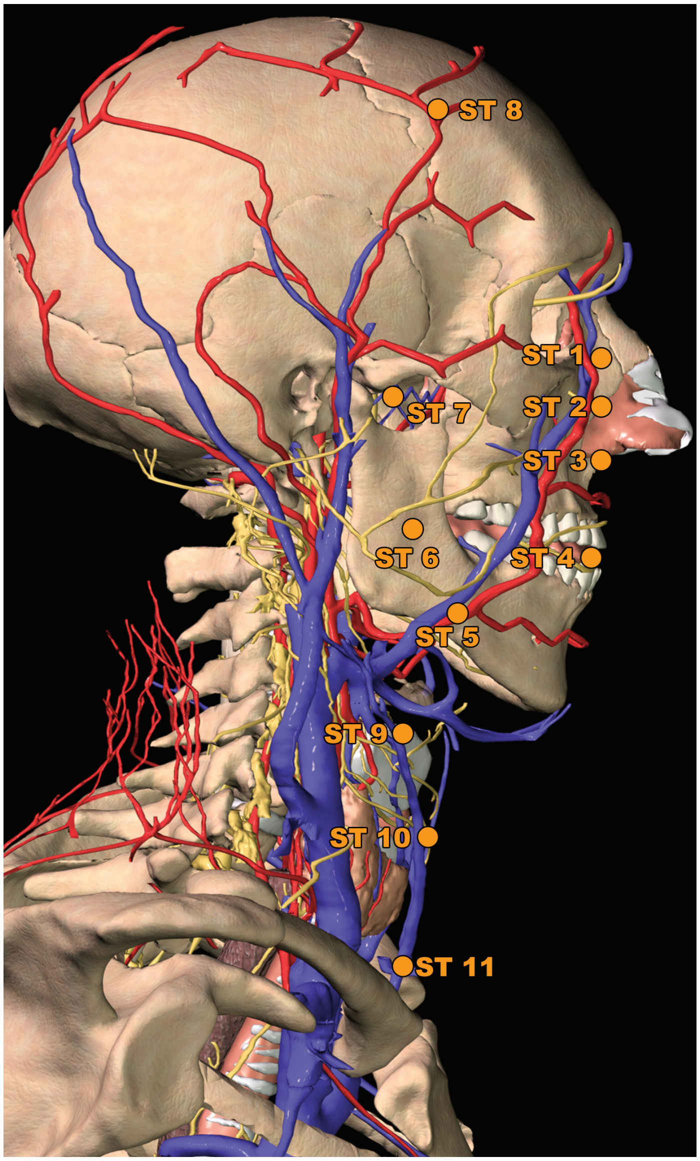
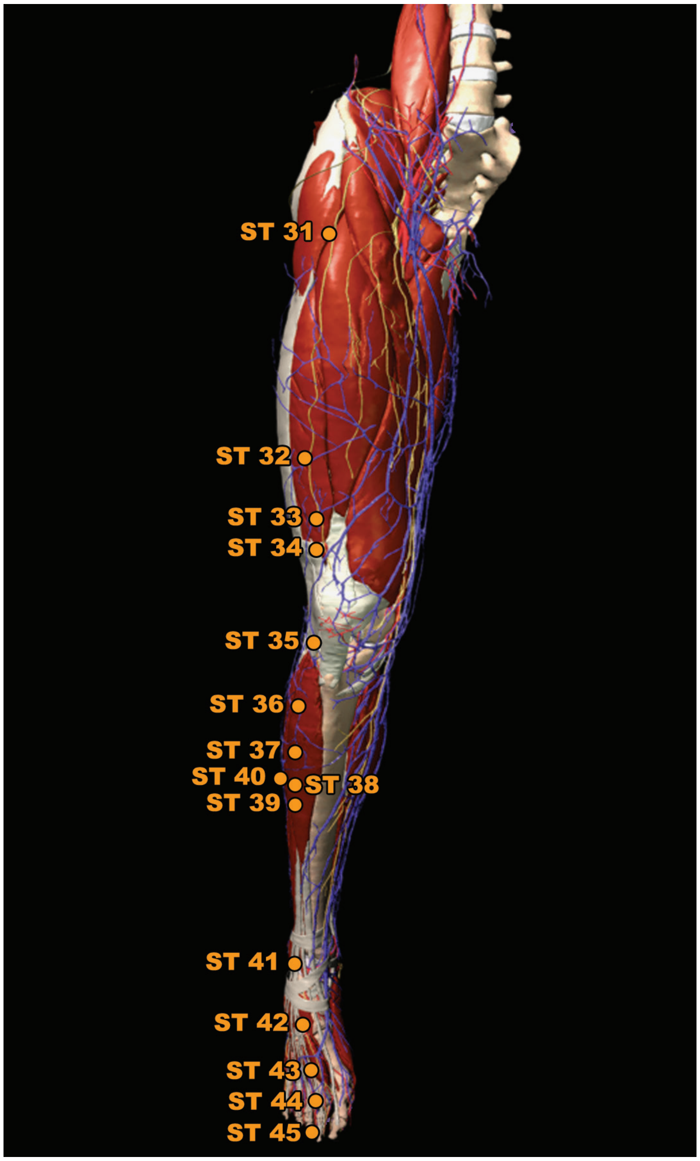
ST 45



This neurovascular view shows how the ST line partners with major vasculature of the head and neck, beginning with the facial artery and vein and continuing on with the jugular and carotid vessels.



ST points on the pelvic limb differentially stimulate the autonomic nervous system, with points on the anterior tibial muscle (ST 36, especially) augmenting parasympathetic function while distal points on the foot neuromodulate sympathetic pathways.

Points along the facial portion of the ST channel address a variety of conditions, including sinusitis, dental pain, nasal stuffiness, mandibular discomfort, ocular distress, head pain, and cranial nerve dysfunction. As the ST line courses caudally, it covers highly vascular territory packed with chemo- and pressure-sensitive nerve endings. For example, ST crosses the carotid sheath, which contains the common and internal carotid arteries, the vagus nerve, the internal jugular vein, the carotid sinus nerve, and sympathetic nerve fibers constituting the carotid periarterial plexuses. This sheath blends with pretracheal and deep cervical fascia; this fascial expanse communicates with the thoracic mediastinum and cavity, representing fascial continuity between the head and chest.

Structures along the ST line link head, neck, and chest in functional ways, as well as anatomically. In the case of the omohyoid muscle, contracting it during yawning tenses the cervical fascia and promotes drainage of blood from the head into the internal jugular vein.[1] Additionally, cervical strap muscles, the pectoralis, and the rectus abdominis muscle, all of which fall along the ST line, participate in the work of breathing when additional force becomes necessary.[2]

This image outlines the relationship between the ST line, the omohyoid muscle, and accessory muscles of respiration.

Several ST points neuromodulates digestion. This begins with seeing food (ST 1); smelling it (ST 2, ST 3); salivating, prehending, and masticating (ST 4-8), and swallowing (ST 9-11). Stimulation of ST lines on the trunk may inhibit gastric motility while those on the pelvic limb (ST 36, especially) promote digestive movement.[3] Neuromodulatory processes that make this happen reflex through the nucleus tractus solitarius and dorsal motor nucleus of the vagus.[4,5] Facial ST points affect digestion as well, first activating the trigeminal nerve and, secondarily, vagal pathways. Sympathoadrenal medullary function may respond to ST line stimulation, as well.[6] From a broader perspective, long-loop reflexes coursing through propriospinal connections link somatic afferent stimulation between the arm and leg. This may provide a neuroanatomic basis for pairing thoracic and pelvic limb lines, such as LI/ST, HT/KI, LU/SP, and so on.[7] More research would need to be done in order to show specificity linking typically associated channels.

ST 1

Cheng Qi “Tear Container”

Between the globe and the midpoint of the infraorbital ridge.

Note: Deep insertion may damage ocular structures. High risk point. No moxa.

Orbital Fat and Its Encapsulating Connective Tissue (OFCT)[1]

- Provides an elastic cushion for the eyelids. May contribute to orbital biomechanics by preventing anterior globe displacement in head trauma, thus stabilizing the eye. OFCT displaces and deforms proportionally and in the same direction as the extraocular muslces and optic nerve during eye movements.

Clinical Relevance: The thixotropic or anti-thixotropic behavior of subcutaneous fat (possibly including that around the orbit) may modify the impact of blunt trauma to the individual. In this case, the consequences of blunt trauma to the eye may depend on the health and viscosity of the overlying subcutaneous tissue and fat.[2] Considering the inclusion of ST 1 in an acupressure or acupuncture “face lift” treatment, ST 1 may hold value for its support of periorbital connective tissue health and repair.

Fascia

- **Capsulopalpebral Fascia:**[3] An analogue of the levator aponeurosis in the upper lid, originates from the belly of the inferior rectus muscle and extends to the lower border of the inferior oblique muscle. The capsulopalpebral head embodies a firm adhesion between the capsulopalpebral fascia and the inferior rectus muscle.

Clinical Relevance: Surgical dissection of the region at and near ST 1 may lead to scarring or fibrosis. Perhaps injury to the floor of the orbit, localized infection, myofascial dysfunction in the region, or congenital disorders could lead to inordinate amounts of restriction in the capsulopalpebral fascia. Neuromodulation and fascial release of the tissue within reach of ST 1 could conceivably improve local tissue health and biomechanics of the eye.

Muscles

- **Orbicularis oculi muscle:** The lacrimal part brings the eyelids and the lacrimal puncta medially. It presses the lacrimal puncta into the lacrimal lake, which allows drainage of lacrimal fluid from the lake into the puncta via capillary action. The palpebral part closes the eyelids gently, helping to keep the cornea moist. The orbital part of the muscle closes the lids more forcefully, as when one squints. This helps prevent dust and glaring light from entering the eye.
- **Inferior oblique muscle (with intraorbital insertion):** Abducts, elevates, and rotates the globe laterally.
- **Inferior rectus muscle:** Depresses, adducts, and rotates the globe laterally.

Clinical Relevance: The periocular and extraocular musculature in this region serve many purposes, from eye movement to closure of the eyelid and management of tear exodus. As such, stimulation of ST 1 can influence multiple problems pertaining to the eye, though careless needling could cause damage to the globe.

Nerves

- **Palpebral branches of the infraorbital nerve (CN V_2):** Provides sensation to the lower lid.
- **Zygomatic and temporal branches of the facial nerve (CN VII):** Provides motor supply to the orbicularis oculi muscle.
- **Oculomotor nerve (intraorbital; CN III):** Innervates the inferior oblique and inferior rectus muscles, as well as the superior and

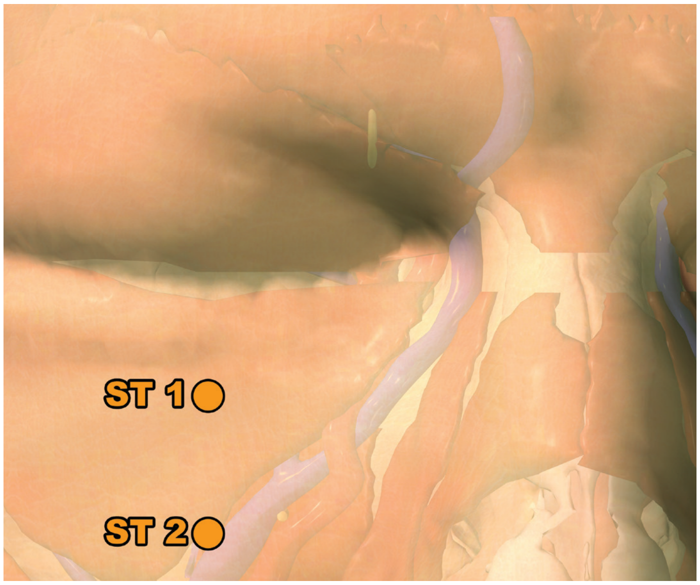

Figure 3-1. This close-up of the right eye and upper portion of the nose shows the origins of the ST channel at ST 1. Some approach ST 1 with an intraorbital needle insertion, beginning at the conjunctival layer of the lid. The Chinese name, “Tear Container”, suits this point well, given its location at the bottom of the infraorbital sac.

medial recti muscles and the levator palpebrae superioris muscle.

Clinical Relevance: The nerves (CN VII and CN III) listed above enliven the muscles just described, while CN V supplies sensation. Thus, conditions such as blepharospasm or facial nerve injury or disease (e.g., Bell's palsy) may benefit from neuromodulation applied to ST 1. Disorders of the extraocular musculature may lead to strabismus. Orbital floor fractures may disrupt or otherwise impair function of the inferior rectus and inferior oblique muscles. Ensuing fibrotic restriction may impair supraduction (upward rotation of the eye around the horizontal axis). CN V$_2$ supplies sensation to the lower lid and may assist with pain control involving the lid or eye.

ST 1
ST 2

Figure 3-4. ST 1 lies on the precipice of the infraorbital rim, illustrating the proximity of the floor of the orbit. In life, the floor would be covered bynd extraocular musculature.

Vessels

- **Lacrimal artery:** From the ophthalmic artery, the lacrimal artery supplies the lacrimal gland, conjunctiva, and eyelids.
- **Infraorbital artery branches:** Supply part of the orbit.
- **Infraorbital vein branches:** Drain into the inferior ophthalmic vein, a tributary of the cavernous sinus.

Clinical Relevance: ST 1 sits along a highly vascularized circumference of an oval surrounding the orbit. As such, deep or aggressive stimulation and needle rotation can lead to ecchymosis within the fragile periocular tissues.

Indications and Potential Point Combinations

- **Eye pain:** ST 1, BL 1, TH 23; tailor approach to source of eye pain (whether intrinsic ocular pain or referred. Substitute other, safer points for ST 1 if possible.
- **Blepharospasm:** For twitching in the lower lid. ST 1, ST 2, GB 1.

ST 2

Si Bai "Four Whites"

In line with the pupil, in the depression of the infraorbital foramen, approximately half cun below ST 1, or about 1 cun below the pupil.

Muscles

- **Orbicularis oculi muscle, orbital part:** The orbital part of the muscle closes the lids in a squinting motion. This helps prevent dust and glaring light from entering the eye.
- **Levator labii superioris muscle:** Raises upper lip and dilates the nostril.
- **Levator anguli oris muscle:** Elevates the corner of the mouth.

Clinical Relevance: The midface musculature can pose challenges for rejuvenation surgery.[3] Myofascial release and local neuromodulation at and around ST 2 may assist a patient in attaining a more youthful appearance, in accordance with claims made concerning an acupressure facelift.

Nerves

- **Infraorbital trunk (CN V_2):** Terminal branch of maxillary n (CN V_2); supplies sensation to the skin of the cheek and lower lid, as well as the lateral nose, inferior septum, and upper lip. Provides dental sensation to the upper premolar incisors and canine teeth. Supplies sensation to the mucosae of the maxillary sinus and upper lip. Trigeminovagal reflexes lead to gastrointestinal modulation.[4]
- **Zygomatic branch of the facial nerve (CN VII):** Provides motor supply to the orbicularis oculi muscle.

Clinical Relevance: Facial and sinus pain, ocular discomfort. Site for infraorbital nerve block, providing local analgesia/anesthesia. Caution should be employed; too vigorous stimulation of the infraorbital nerve may lead to trigeminocardiac reflex.[5] Activation of trigeminal nerve endings in this region may cause a blink reflex due to trigeminal connections to facial nerve nuclei in the brainstem.[6] Cluster headache treatment through trigeminoautonomic reflexes. Connections between the infraorbital nerve and cervical musculature (i.e., the trigeminocervical reflex) participate in chronic tension-type headaches, suggesting benefit of neuromodulating infraorbital nerve territory for these patients.[7]

Vessels

- **Infraorbital artery branches:** Supply the inferior eyelid, lacrimal sac, side of the nose, and upper lip.
- **Anastomosing branches from the lateral nasal artery (the continuation of the facial artery) to the superior labial artery (a branch of the facial artery):** These arteries supply the upper lip and the ala, dorsum and septum of the nose.
- **Infraorbital vein branches:** Drain into the inferior ophthalmic vein, a tributary of the cavernous sinus.
- **Tributaries of facial vein:** The facial vein drains directly or indirectly into the inferior jugular vein, and communicates with the superior ophthalmic vein (which drains into the cavernous sinus) at the medial angle of the eye.

Clinical Relevance: Vessels in the vicinity of ST 2 may suffer damage during midface lift.[8] Similarly, caution is advised when needling this region.

Indications and Potential Point Combinations

- **Eye conditions:** Eye pain and irritation, blepharospasm: ST 2, BL 2, TH 23, GB 1, ST 36.
- **Sinus congestion:** ST 2, ST 3, GV 24.5, GB 14, LI 4.
- **Trigeminal neuralgia:** ST 2, ST 7, LI 4, BL 10.
- **Maxillary pain:** ST 2, ST 3, ST 4, ST 7.
- **Dental pain, maxillary arcade:** ST 2, ST 3, LI 19, LI 4, LU 7.
- **Gastric motility issues, colic:** ST 2, ST 36, ST 25, SP 6.

Evidence-Based Applications

- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with **keratoconjunctivitis sicca** (KCS, or dry eye).[1]
- Afferents from ST 2, like ST 36, affect gastric myoelectric activity. In the case of ST 2, the nucleus tractus solitarius (NTS) receives somatic afferent projection from the face via the sensory nucleus of the trigeminal nerve. The NTS, a major visceral sensory nucleus in the medulla oblongata, receives afferent input from several somatic and visceral sources. This includes information from the oculomotor, facial, and vagus nerves, in addition to the trigeminal nerve. The dorsal vagal complex (DVC) comprises the NTS and the dorsal motor nucleus of the vagus (DMNV). The DVC sends efferent vagal neurons to the viscera. As such, it participates in the **regulation of gastric function.**[2]

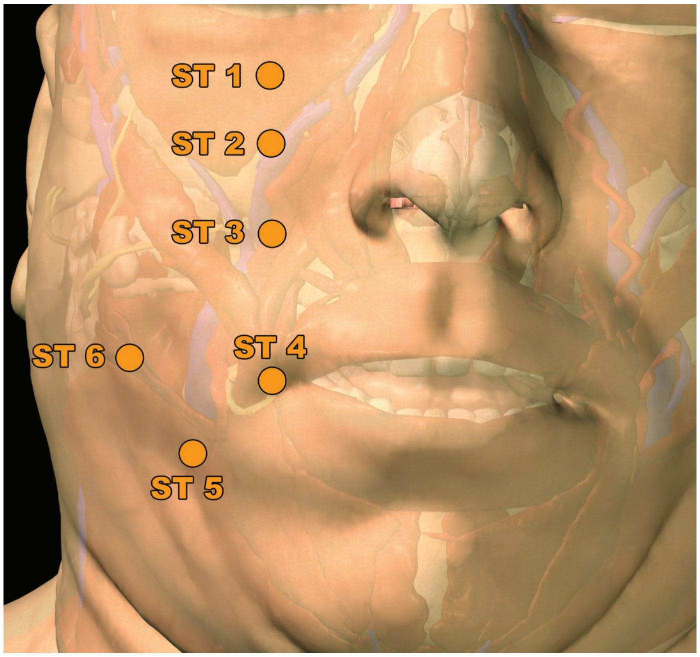

Figure 3-5. ST 1 through ST 4 line up below the pupil when the patient is looking straight ahead. The infraorbital nerve exits the skull at the infraorbital foramen, located at ST 2. Known as the "Four Whites" point, ST 2 helps to clear redness from the eye, allowing the sclera to turn white again. This happens by means of reflexes involving the infraorbital nerve and sympathetic pathways.

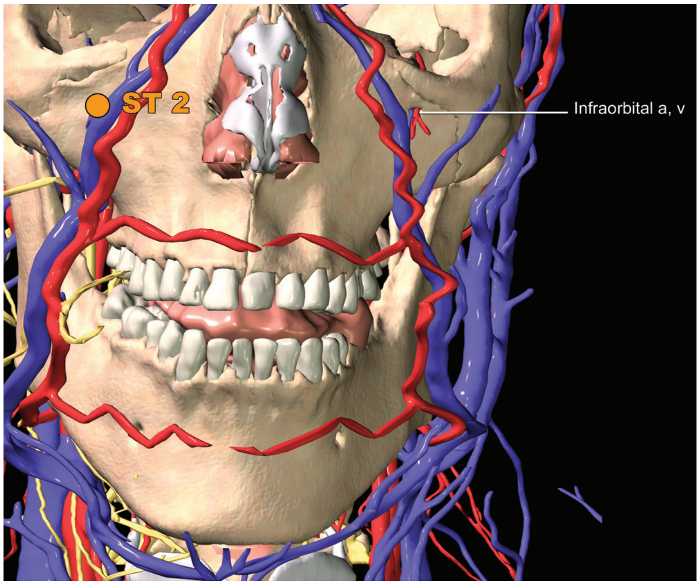
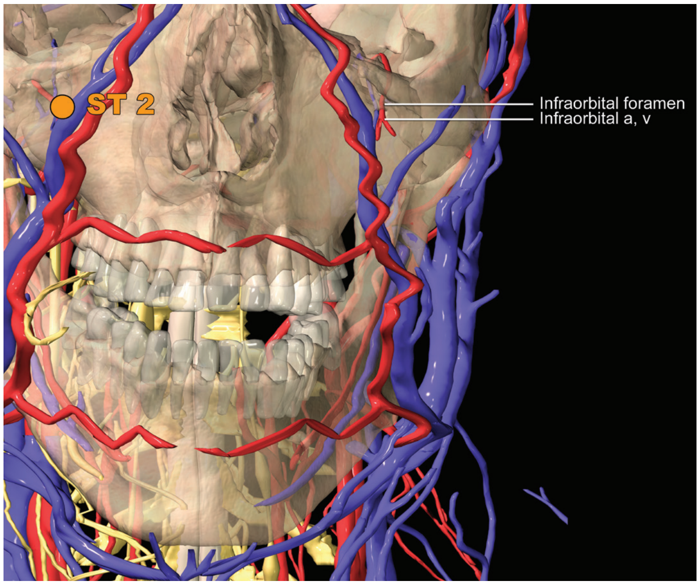
Figure 3-6. ST points on the face relate to one or more muscles of facial expression, all of which receive innervation from the facial nerve. As shown here, ST 2 resides between the orbicularis oculi muscle and the levator labii superioris muscle.



ST 2
Infraorbital a, v

Figure 3-7. The infraorbital foramen transmits the infraorbital nerve, a sensory branch of the trigeminal nerve. The nerve travels through the infraorbital foramen with its companions, the infraorbital artery and vein, shown in this image. The structure-function relationship between the nerve supply and the point indications becomes clear when considering the actions of the nerve and the indications for the point. That is, the infraorbital nerve supplies the maxillary sinus mucosa, the skin of the upper cheek, maxillary arcade teeth (incisors, canines, and premolars) and adjacent gingiva, skin and conjunctiva of the lower eyelid, a portion of the nose, and the skin and upper lip mucosa. This matches the indications for ST 2, which include sinus congestion and pain, maxillofacial pain, trigeminal neuralgia, dental pain, and ocular dysfunction.



ST 2

ST 3

Ju Liao "Great Crevice" or "Greater Bone-Hole"

Directly below the pupil, level with the lower border of the alae nasi, lateral to the nasolabial groove.

Note: ST 3 and GB 29 share the name "Ju Liao", although the translation for Ju Liao when referring to GB 29 is sometimes given as "Squatting Crevice" or "Stationary Crevice". This illustrates the confusion that exists in acupuncture nomenclature. It also emphasizes the importance of including anatomical locations and the alphanumeric designation when referring to point placement, especially for research studies.

Muscles

- **Levator labii superioris muscle:** Raises upper lip and dilates the nostril.
- **Levator anguli oris muscle:** Elevates the corner of the mouth.

Clinical Relevance: Acupuncture/acupressure face lift, facial nerve injury.

Nerves

- **Infraorbital nerve (CN V_2):** Terminal branch of maxillary nerve (CN V_2); supplies sensation to the skin of the cheek and lower lid, as well as the lateral nose, inferior septum, and upper lip. Provides dental sensation to the upper premolar incisors and canine teeth. Supplies sensation to the mucosae of the maxillary sinus and upper lip. Trigeminovagal reflexes participate in the modulation of gastrointestinal motility.[2]
- **Zygomatic branches of facial nerve (CN VII):** Supplies the muscles of facial expression inferior part of the orbicularis oculi muscle as well as other facial muscles inferior to the orbit.
- **Buccal branches of facial nerve (CN VII):** Supplies the buccinator muscle and muscles of the upper lip (i.e., the orbicularis oris and levator labii superioris mm).

Clinical Relevance: Acupuncture/acupressure face lift, facial nerve injury, maxillary sinusitis, trigeminal nerve injury, trigeminal neuralgia, cluster headache,[3] modulation of digestive system motility through trigeminovagal reflexes. Connections between the infraorbital nerve and cervical musculature (i.e., the trigeminocervical reflex) participate in chronic tension-type headaches, suggesting benefit of neuromodulating infraorbital nerve territory for these patients.[4]

Vessels

- **Infraorbital artery branches:** Supply the inferior eyelid, lacrimal sac, side of the nose, and upper lip.
- **Infraorbital vein branches:** Drain into the inferior ophthalmic vein, a tributary of the cavernous sinus.
- **Anastomosing branches from the lateral nasal artery (the continuation of the facial artery) to the superior labial artery (a branch of the facial artery):** These arteries supply the upper lip and the ala, dorsum and septum of the nose.
- **Tributaries of facial vein:** The facial vein drains directly or indirectly into the inferior jugular vein, and communicates with the superior ophthalmic vein (which drains into the cavernous sinus) at the medial angle of the eye.

Clinical Relevance: One should exercise caution needling this region of the face. Note the multiplicity of large vessels occupying this site of the face as shown in Figure 3-9.

Indications and Potential Point Combinations

- **Sinus problems, especially maxillary sinusitis:** ST 3, LI 19, LI 20, GV 23, BL 10.
- **Facial paralysis affecting the zygomatic or buccal branch of the facial nerve:** ST 3, ST 7, TH 17.
- **Dental pain:** ST 3, LI 19, LI 4, LU 7.
- **Blepharospasm:** ST 3, GB 1, TH 23, BL 2.
- **Dryness of the eyes and mouth:** ST 3, ST 7, TH 23.

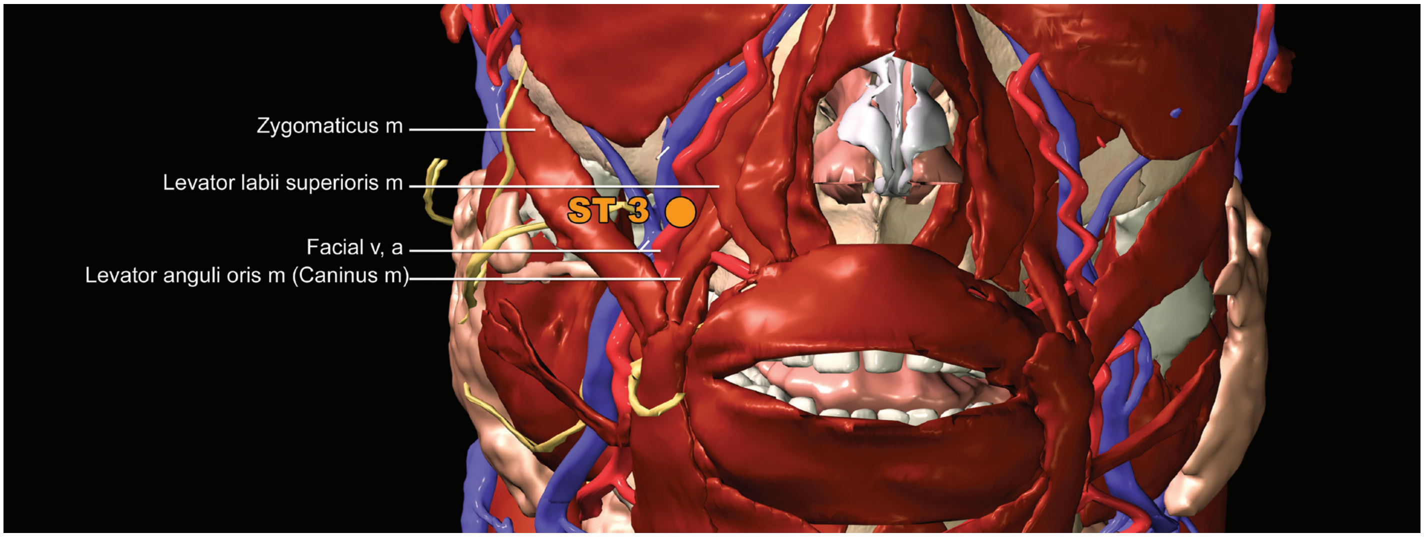

Figure 3-9. ST 3 sits at the intersection of several facial muscles and vessels. Its proximity to prominent veins implies benefit for edema of the lips and cheeks but also suggests a cautious approach with needling in order to avoid traumatizing facial vessels. Perhaps a safer approach in swollen circumstances would involve the introduction of acupressure/massage or carefully delivered laser therapy.

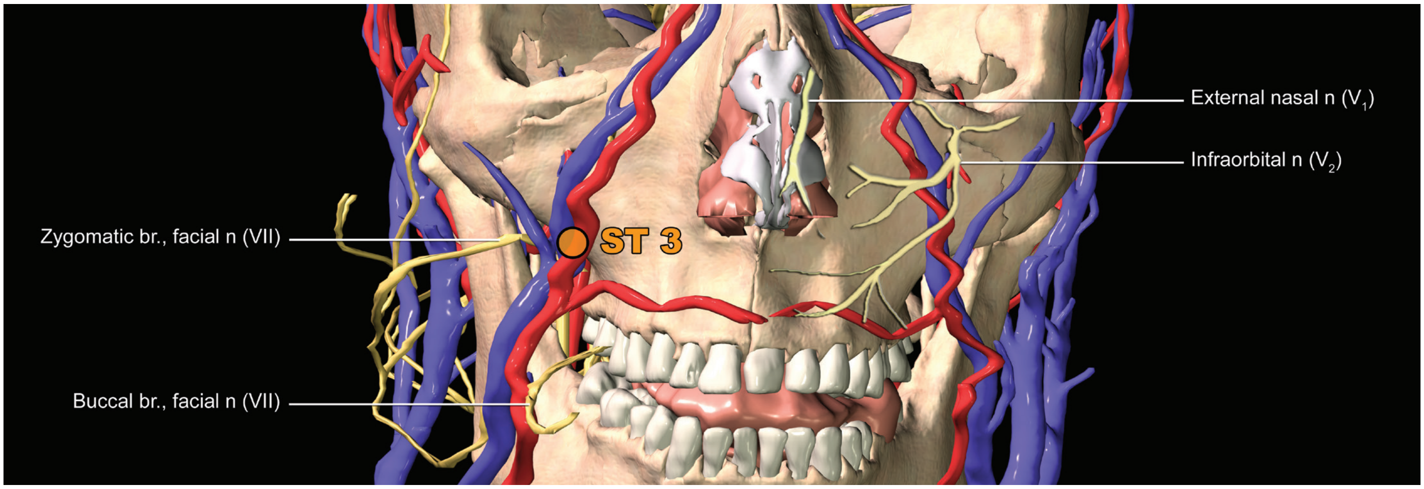

External nasal n (V_1)

Zygomatic br., facial n (VII)
ST 3
Buccal br., facial n (VII)

Figure 3-10. Note the skeletal contour in the maxilla where the sharp angle on the bony ridge forms a "Great Crevice", the descriptive name for ST 3. Nerves supplying this point include the infraorbital nerve (from CN V) and the zygomatic and buccal branches of the facial nerve. The infraorbital nerve mediates sinus, ocular, facial, and dental pain, affording several applications for neuromodulation, while facial nerve branches offer treatment pathways for facial nerve injury.

Figure 3-11. This cross section at ST 3 demonstrates the proximity of ST 3 to the maxillary sinus (illustrated in blue).

Evidence-Based Applications

- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of xerostomia due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[1]

ST 4

Di Cang "Earth Granary"

Lateral to the oral labial commissure (i.e., corner of the mouth), in the continuation of the nasolabial groove, directly in line with the pupil, below ST 3.

Muscles

- **Marginal part of the orbicularis oris muscle:** Sphincter of the mouth; works with the tongue to hold food between the teeth while chewing. Also aids in speech articulation.
- **Buccinator muscle:** Aids in mastication by pressing the cheek against the molars while chewing.

Clinical Relevance: Muscles of facial expression that may become dysfunctional from facial nerve injury.

Nerves

- **Infraorbital nerve (CN V_2):** Terminal branch of maxillary nerve (CN V_2); supplies sensation to the skin of the cheek and lower lid, as well as the lateral nose, inferior septum, and upper lip. Provides dental sensation to the upper premolar incisors and canine teeth. Supplies sensation to the mucosae of the maxillary sinus and upper lip.
- **Buccal nerve from mandibular nerve (CN V_3):** A small sensory branch of the mandibular nerve, the buccal nerve provides sensation to the cheek skin and mucosal lining, as well as the posterior portion of the buccal gingiva.

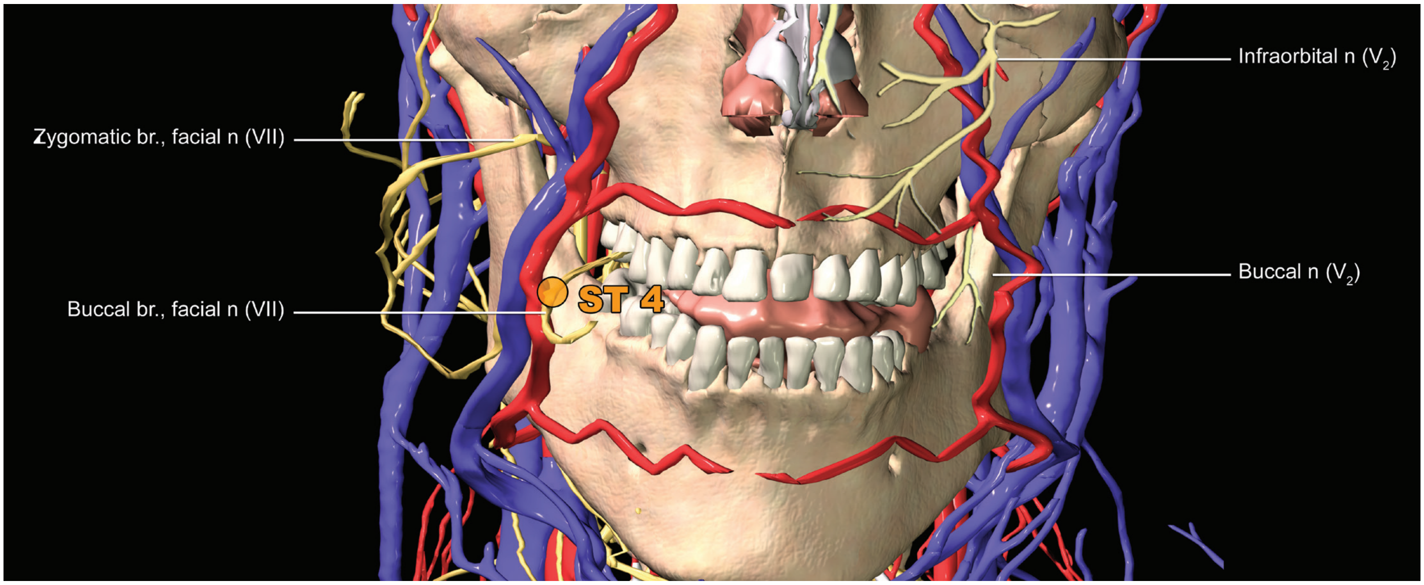

Figure 3-12. Like other points on the face, ST 4 receives dual nerve supply from the facial and trigeminal nerves. Here, the innervation of ST 4 by the buccal branch of the facial nerve explains its application for problems with facial nerve injury (including, specifically, difficulty keeping food or saliva in the mouth) from stroke or Bell's palsy. The buccal nerve, a sensory branch of the trigeminal nerve, provides sensation to a small, thumb-sized section of the cheek skin and underlying mucous membrane, as well as the posterior part of the buccal gingiva.

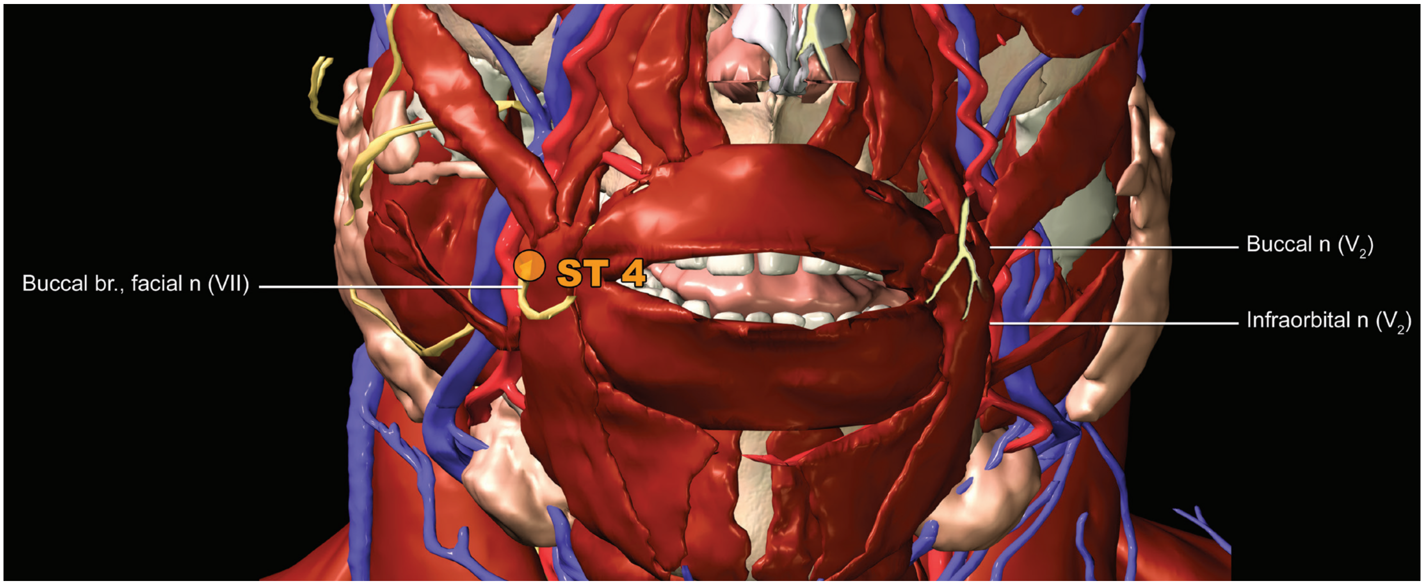

Figure 3-13. ST 4 promotes the ability to retain food in the mouth. Needling this area impacts nerves that control these muscles, specifically the orbicularis oris and the buccinator. The point's name, "Earth Granary", refers to ST 4 for its ability to maintain the oral vestibule as a storehouse for grain or food.

Figure 3-14. Note the proximity of ST 4 to the vestibule, buccinator muscle, and orbicularis oris m.

- **Buccal branches of facial nerve (CN VII):** Supplies the buccinator muscle and muscles of the upper lip (i.e., the orbicularis oris and levator labii superioris muscles).

Clinical Relevance: Restoring the ability to retain food in the mouth requires adequate function of the sensory (trigeminal n) and motor (facial n) nerves that feed this point.

Vessels

- **Facial artery:** Provides the major blood supply to the face.
- **Facial vein:** Provides the venous drainage of the face.

Clinical Relevance: Neuromodulation at ST 4 involves the nervi vasorum associated with the facial vessels, promoting local circulatory supply and venous drainage.

Indications and Potential Point Combinations

- **Problems of lower lip, teeth, and jaw**
- **Post-stroke problems:** drooling (sialorrhea), facial paralysis, and facial tension: ST 4, ST 3, TH 17.
- **Trismus:** ST 4, ST 6.
- **Facial nerve injury, buccal branch:** ST 4, ST 6, ST 7, TH 17.
- **Oral or lip sores:** ST 4, ST 36.
- **Toothache, dental analgesia:** ST 4, LI 19, LI 4, LU 7.

Evidence-Based Applications

- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flo w in the skin over the parotid gland in patients with **Sjögren's syndrome**.[1]

References

1. Blom M, Lundeberg T, Dawidson I, and Angmar-Mansson. Effects on local blood flux of acupuncture stimulation used to treat xerostomia in patients suffering from Sjögren's Syndrome. *Journal of Oral Rehabilitation.* 1993;20:541-548.

ST 5

Da Ying "Great Reception"

On the cheek, on the anterior border of the masseter muscle, in the groove-like depression that appears there when the teeth are clenched.

Muscles

- **Platysma muscle:** Helps depress mandible and participates in the grimace expression.
- **Masseter muscle:** Closes and retrudes (thrusts back) the jaw.

Clinical Relevance: Clinical indications include myofascial dysfunction associated with mastication and temporomandibular dysfunction. Myofascial trigger points in the masseter and other muscles of mastication may produce tinnitus, suggesting that addressing myofascial dysfunction with neuromodulation (acupuncture, massage, laser therapy) could provide meaningful benefits for this often intractable condition.[3] In addition to the ear, trigger points in the masseter muscle may refer to the mandible, molars, maxilla, TMJ, or eyebrow.

Nerves

- **Buccal nerve from mandibular nerve (CN V_3):** A small sensory branch of the mandibular nerve that provides sensation to the cheek skin and its mucosal lining, as well as the posterior portion of the buccal gingiva.
- **Marginal mandibular branch of facial nerve (CN VII):** Supplies the risorius muscle and muscles of the lip and chin.
- **Cervical branch of facial nerve (CN VII):** Supplies the platysma muscle.
- **Masseteric nerve (motor branch from mandibular nerve, CN V_3):** Innervates the masseter muscle.

Clinical Relevance: Facial nerve injury, facial pain involving the masseter muscle.

Vessels

- **Facial artery:** Provides the major blood supply to the face.
- **Facial vein:** Provides the venous drainage of the face.

Clinical Relevance: ST 3, ST 4, and ST 5 line up with the facial a and v, implicating their effects on local blood supply and venous drainage.

Indications and Potential Point Combinations

- **Facial, cheek or jaw pain:** ST 5, ST 3, ST 6, ST 7, BL 10.

Evidence-Based Applications

- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[1]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **KCS**.[2]
- Manual and electrical acupuncture eat ST 5, ST 6, ST 7, GV 20, GV 24, and several additional points for patients with **dysphagia after chemoradiation** experienced reduced symptom severity.[4]

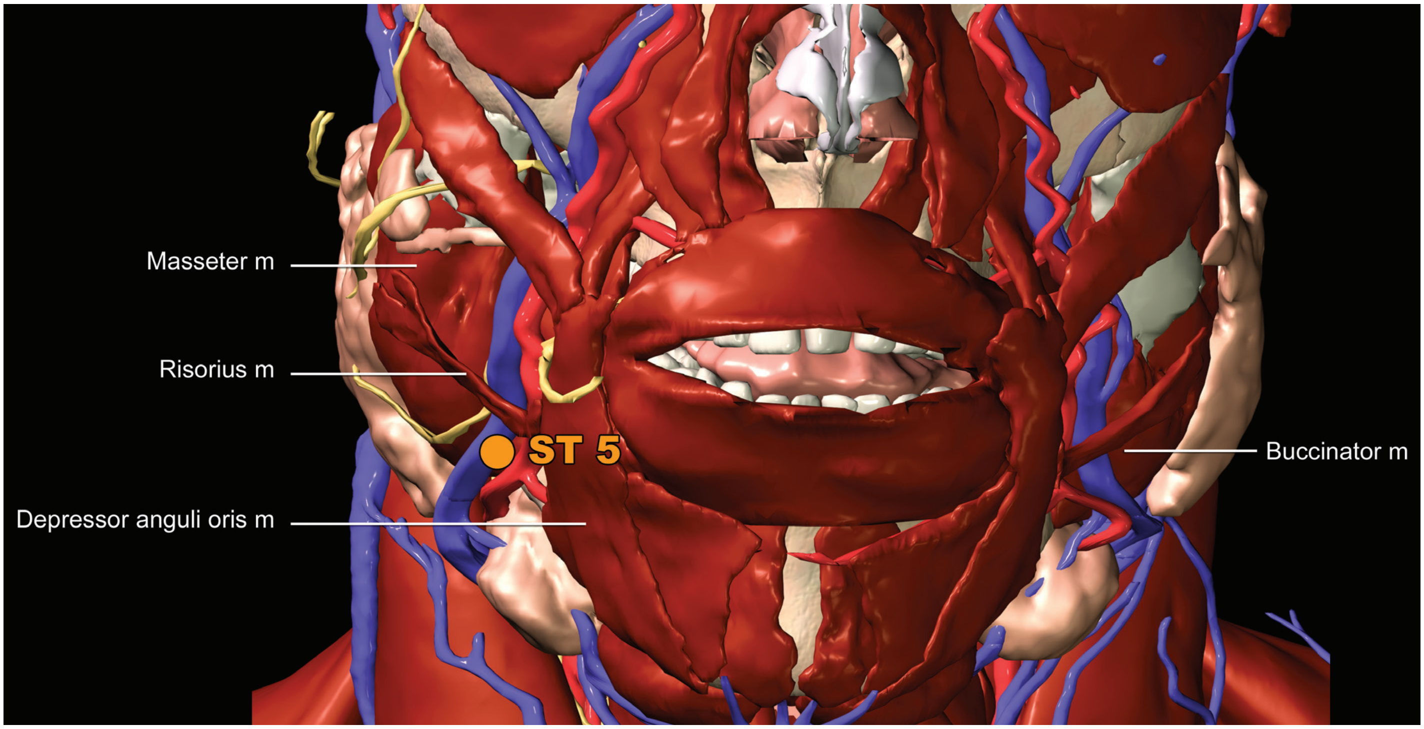

Figure 3-15. ST 5 sits at the intersection of mouth and cheek, explaining its analgesic effects for both mouth and cheek. The name "Great Reception" connotes a celebration of the intersecting neurovasculature.

ST 6

Jia Che "Jaw Bone" or "Cheek Carriage"

On the cheek, one finger's breadth anterior and superior to the angle of the mandible, in the belly of the masseter muscle. At the prominence of the muscle when the teeth are clenched.

Note: The parotid duct crosses the masseter muscle in the region of ST 6.

Muscles

- **Masseter muscle:** Closes and retrudes (thrusts back) the jaw.

Clinical Relevance: Psychophysical stress increases masseter muscle tension and local tissue irritability.[5] Stimulation of ST 6, ST 7, and LI 4 reduced TMJ symptoms and reduced masseter muscle activity on EMG.[6] Myofascial trigger points in the masseter and other muscles of mastication may produce tinnitus, suggesting that addressing myofascial dysfunction with neuromodulation (acupuncture, massage, laser therapy) could provide meaningful benefits for this often intractable condition.[7] In addition to the ear, trigger points in the masseter muscle may refer to the mandible, molars, maxilla, TMJ, or eyebrow.

Nerves

- **Great auricular nerve (C2, C3 – arises from the cervical plexus):** Innervates the parotid gland sheath and the skin over the parotid gland; also supplies the posterior aspect of the auricle and the skin between the angle of the mandible and the mastoid process.
- **Buccal nerve from mandibular nerve (CN V_3):** A small sensory branch of the mandibular nerve that provides sensation to the cheek skin and its mucosal lining, as well as the posterior portion of the buccal gingivae.
- **Marginal mandibular branch of facial nerve (CN VII):** Supplies the risorius muscle and muscles of the lip and chin.
- **Masseteric nerve (motor branch from mandibular nerve, CN V_3):** Innervates the master muscle.

Clinical Relevance: Perhaps not surprisingly, nerves supplying ST 6 pertain to activities related to eating, including mastication, salivation, cheek sensation, and food retention within the oral cavity.

Vessels

- **Masseteric artery and vein:** The small masseteric artery, a branch of the maxillary (formerly internal maxillary) artery, passes through the mandibular notch and supplies the deep surface of the masseter muscle. It anastomoses with masseteric branches of the external maxillary and transverse facial arteries. The facial (formerly external maxillary) artery winds around the ventral aspect of the mandible along a passageway called the "groove for the external maxillary artery", near ST 5. The masseteric nerve, a branch of the mandibular nerve (CN V_3), accompanies the masseteric artery and vein
- **Facial vein:** Provides the venous drainage of the face.

Clinical Relevance: Unlike ST 3, ST 4, and ST 5, ST 6 does not line up along the facial vessels, instead landing squarely over the masseter muscle consistent with its trigger point nature. Deep and superficial blood flow to the masseter muscle differ, with more flow supplying deeper sites. Blood flow increases significantly during biting. These regional differences may relate to specific muscle fiber types and recruitment that characterize the masseter, and may hold implications for trigger point development and deactivation with needling.[8] Trigger points exhibit reduced blood flow and perfusion, setting up a vicious cycle that includes of muscle tension clamping down on vessels, unhappy nerves from reduced blood supply, and continued tension from nerve irritation. Improving blood flow to the deep and superficial regions of the masseter muscle may alleviate pain associated with mastication as well as secondary problems such as tinnitus from regional myfoascial restriction.

Indications and Potential Point Combinations

- **Temporomandibular joint (TMJ) pain:** ST 6, SI 19, TH 21, local trigger points in the temporalis, trapezius, and cervical region.

Evidence-Based Applications

- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders**, prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[1]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 6, ST 7, and SI 17, splint therapy, and point injection therapy

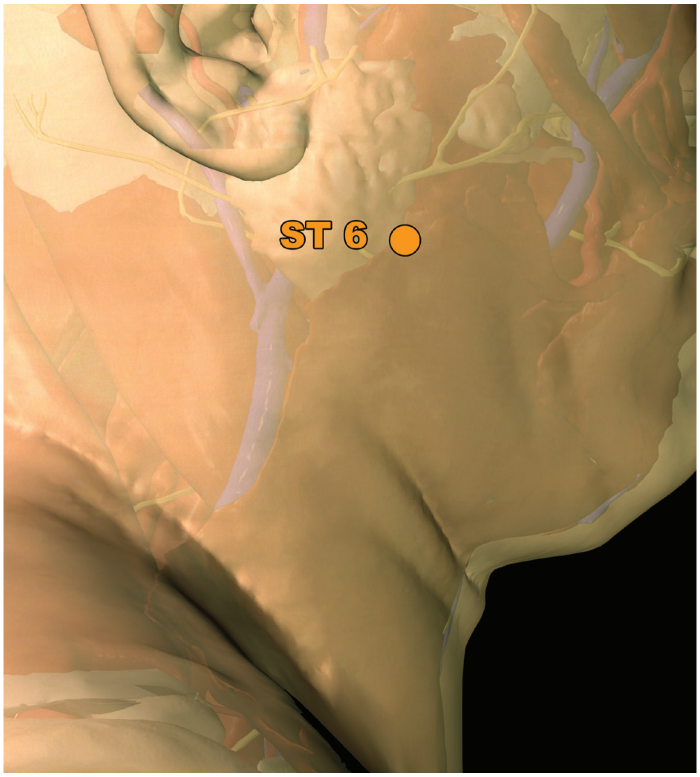

Figure 3-17. This image shows the location of ST 6, "Cheek Carriage", on the face.

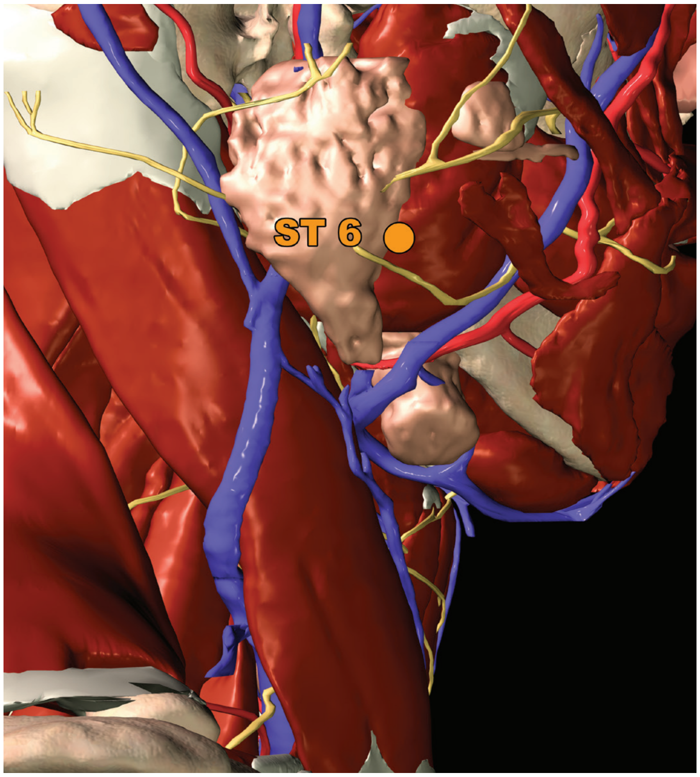

Figure 3-18. As a site for myofascial trigger point deactivation, ST 6 sits centrally upon the belly of the masseter muscle. Point applications include jaw pain and trismus (i.e., inability to fully open the mouth), although referred pain from the masseter can travel to the molars (upper and lower), the ear, and the eyebrow. After exiting the stylomastoid foramen, the facial nerve trunk gives off the posterior auricular nerve, coursing caudally over the sternocleidomastoid muscle. The facial nerve then enters the parotid gland, forming the parotid plexus, consisting of five terminal branches: the temporal, zygomatic, buccal, marginal mandibular, and cervical branches of the facial nerve.

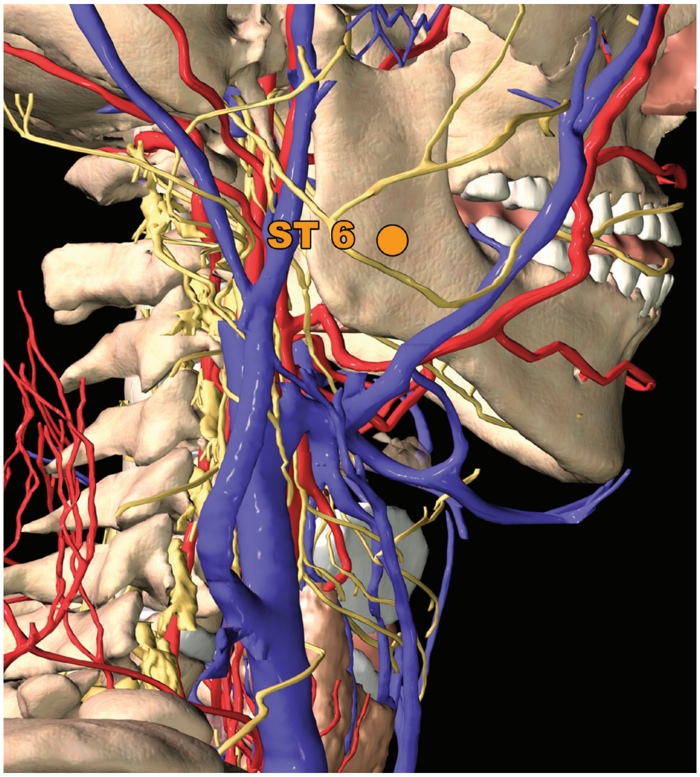

Figure 3-19. One can also find ST 6, "Jaw Bone", one fingerbreadth anterior and superior to the angle of the mandible, as shown here.

suggested that this combination was effective for managing **temporomandibular disorders.**[2]

- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[3]
- Acupuncture at LI 4, ST 6, ST 7, and TH 17 was superior to placebo for the prevention of **postoperative dental pain.**[4]

ST 7

Xia Guan "Below the Joint" ("Joint" = TMJ)

In the depression below the zygomatic arch and anterior to the condyloid process of the mandible (the posterior "prong" of the mandible), nearly level with the tragus of the ear. Needle with the mouth closed, but find the point with the mouth open, in order to locate the condyloid process of the mandible. Rest a finger on the condyloid process with the mouth open; when the mouth closes, the finger will fall into ST 7.

Gland

- **Parotid gland:** The largest of the three paired salivary glands, the parotid gland it enclosed within a tough fascial capsule called the parotid sheath.

Connective Tissues

- **Temporomandibular ligament:** This ligament represents a thickening of the portion of the temporomandibular capsule. It consists of two parts. The outer oblique portion limits the extent of mouth opening; the inner horizontal part limits posterior movement of the condyle and disc.

Clinical Relevance: The temporomandibular ligament controls or restrains mandibular motion and prevents tissue from being compressed caudal to the condyle. TMJ pain may originate in the synovial joint capsule, surrounding musculature, and associated connective tissue.

Muscles

- **Masseter muscle:** Closes and retrudes (thrusts back) the jaw. The masseter muscle consists of a deep and superficial portion, each with different blood supply (i.e., branches of the maxillary and facial arteries, respectively). The deep portion of the masseter muscle lies adjacent to ST 7.
- **Lateral pterygoid muscle:** This muscle has two heads. The dorsal (or superior) head inserts onto the articular disc and fibrous capsule of the TMJ, while the ventral (or inferior) head inserts onto the neck of the condyle of the mandible. Trigger points in the lateral pterygoid muscle refer to the zygomatic arch and the TMJ.

Clinical Relevance: These muscles of mastication can experience myofascial dysfunction and lead to a number of chronic, potentially debilitating pain syndromes, most notably TMJ disorder. Trigger points in the masseter muscle may refer pain to the upper and lower molars, the ear, the TMJ, and the superciliary ridge (the bony ridge beneath the eyebrow), thereby mimicking frontal sinus pain. Lateral pterygoid triggers refer to the tragus and the zygomatic arch.

Nerves

- **Auriculotemporal nerve (CN V_3):** This sensory mandibular nerve branch sends articular fibers to the temporomandibular joint. It provides sensation to the skin anterior to the ear and of the posterior temporal region. Also supplies the tragus and part of the helix of the auricle, and the roof of the external acoustic meatus and the upper tympanic membrane. In addition to its somatosensory aspects, the auriculotemporal nerve carries postganglionic parasympathetic fibers to the parotid gland. These secretomotor fibers originate in the glossopharyngeal nerve (CN IX) as the lesser petrosal nerve, synapse in the otic ganglion, and travel with the auriculotemporal nerve until the fibers leave the nerve to supply the parotid gland.
- **Temporal branch of the facial nerve (CN VII):** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior part of the orbicularis oculi muscle.
- **Zygomatic branch of the facial nerve (CN VII):** Supplies the inferior part of the orbicularis oculi muscle as well as other muscles of the face inferior to the orbit.
- **Masseteric nerve (motor branch from mandibular nerve, CN V_3):** Innervates the master muscle.
- **Lingual nerve (CN V_3):** The lingual nerve exits the mandibular division of the trigeminal ganglion and courses beneath the lateral pterygoid muscle, medial and rostral to the inferior alveolar nerve. It provides somatosensory information from the anterior two-thirds of the tongue, the floor of the oral cavity, and the lingual gingivae.
- **Inferior alveolar nerve (CN V_3):** Forms the inferior dental plexus, which sends branches to the ipsilateral mandibular teeth.
- **Otic ganglion (parasympathetic):** Presynaptic parasympathetic fibers, mostly from the glossopharyngeal nerve, synapse here. The postsynaptic fibers provide secretory function to the parotid

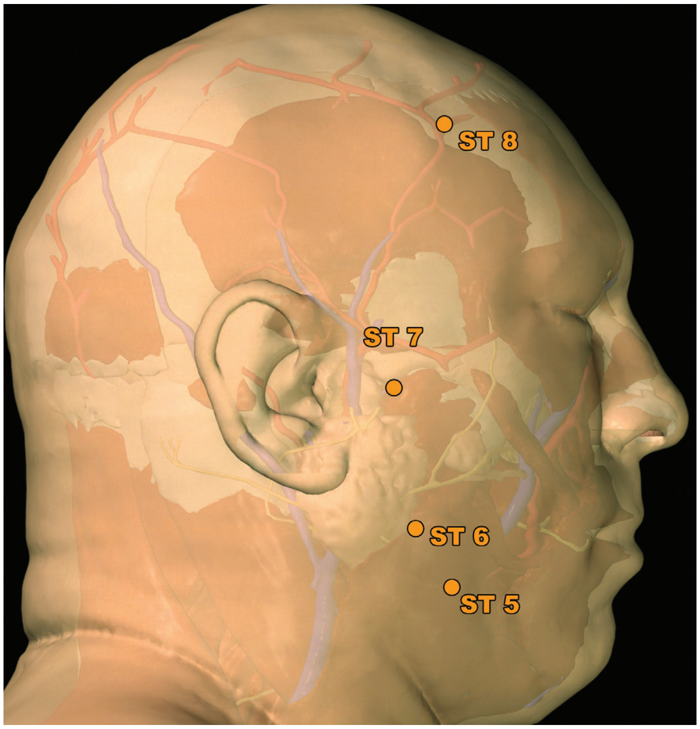

Figure 3-20. This image illustrates the layout of ST 5, ST 6, ST 7, and ST 8. The arc they describe traverses muscles of mastication beginning with the masseter muscle at ST 5 and ST 6, the lateral pterygoid and masseter at ST 7, and the temporalis at ST 8. Making a lifting, sweeping motion from ST 5 to ST 8 helps to release downward droop and tension in the face, encouraging a more youthful appearance to emerge.

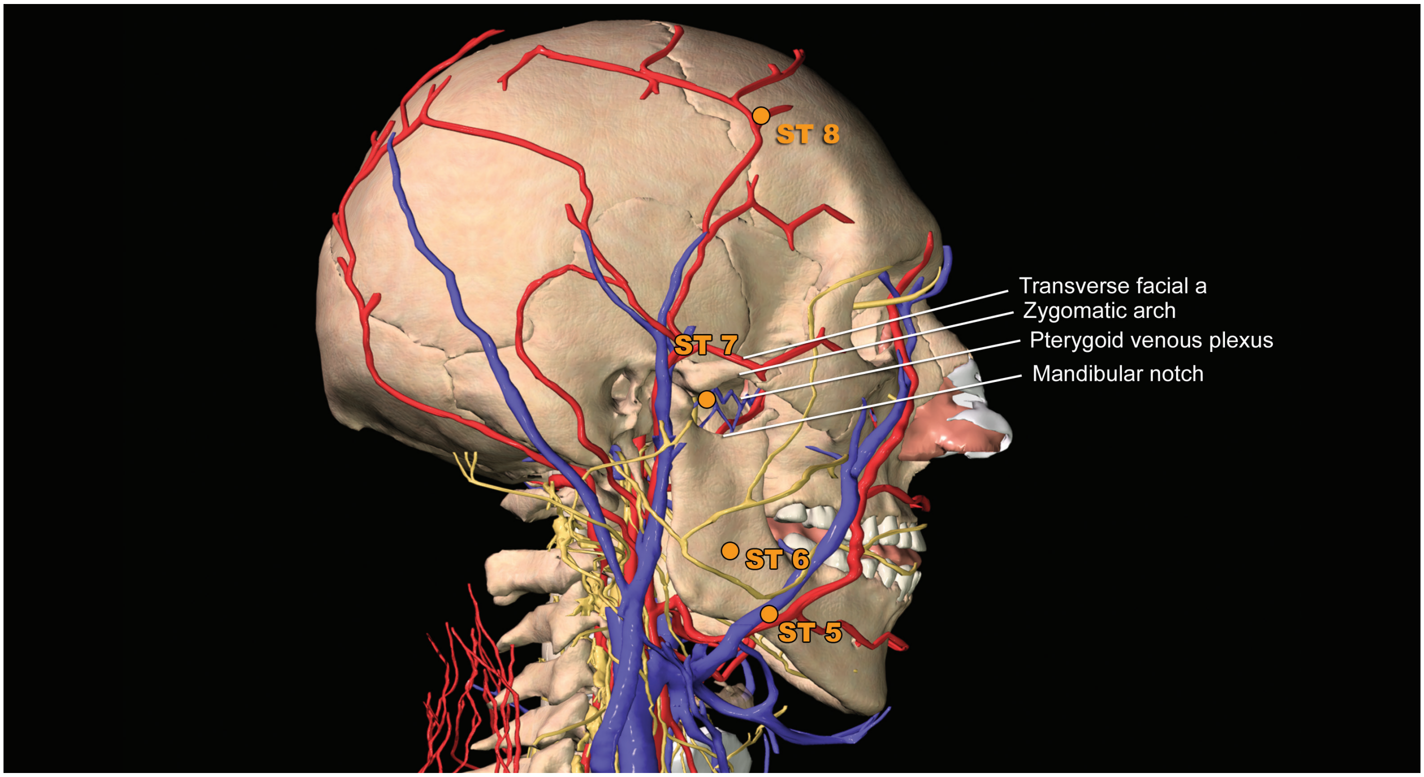

Figure 3-21. ST 7, "Below the Joint", resides in the depression formed between the mandibular notch and the zygomatic arch, anterior and inferior to the TMJ (temporomandibular joint). More than merely an articulation between the temporal bone and the mandible, the TMJ embodies an assembly of muscular and ligamentous connections attaching not only these bones but instead creating a functional complex called the "cranio-cervico-mandibular" system.[9] These extensive connections help provide insight into the complexity of the TMJ, multifactorial causes of dysfunction, and multimodal interventions often required for successful alleviation of TMJ disorders.

gland and pass from the otic ganglion to the parotid gland via the auriculotemporal nerve.

Clinical Relevance: As indicated by the extensive list above, many nerves either course through or supply the ST 7 region. They carry sensory, motor, and autonomic information to and from a wide array of structures. As such, myofascial dysfunction in the TMJ locale may interrupt or impair normal neural traffic, leading to peripheral and central sensitization. Neuromodulation at ST 7 by means of acupuncture and related techniques (e.g., laser therapy, massage) may thereby impart analgesia and myofascial relaxation for patients with TMJ dysfunction and concomitant problems such as tinnitus, neck pain, and stress.

Vessels

- **Transverse facial artery:** Arises from the superficial temporal artery and divides into several braches to supply the parotid gland, parotid duct, and masseter muscle as well as the skin of the face. Anastomoses with the facial, masseteric, buccinator, and infraorbital arteries.
- **Inferior alveolar artery:** A branch of the maxillary artery, the inferior alveolar artery supplies the mandible, gingivae, and teeth.
- **Middle meningeal artery**: A branch of the maxillary artery that supplies the dura mater and calvaria.
- **Maxillary artery:** The larger of the two terminal branches of the external carotid artery; divides into three parts to supply a large area and many structures on the side of the face. ST 7 relates with the 1st part of the artery. Branches off of the first or mandibular portion include the deep auricular, anterior tympanic, middle meningeal, inferior alveolar, and accessory meningeal arteries.

Clinical Relevance: Normalizing blood flow to the muscles, nerves, and ganglia with neuromodulation helps reduce nerve irritability and trigger point dysfunction.

Indications and Potential Point Combinations

- **Facial pain, trigeminal neuralgia:** Identify painful region and structure to the extent possible, and treat accordingly. ST 7; consider BL 2 for supraorbital nerve distribution, ST 2 for infraorbital nerve distribution, ST 5 for mandibular nerve distribution.
- **Dental pain, lower arcade:** ST 7, ST 5, LI 4, LU 7, CV 24.
- **TMJ:** ST 7, ST 6, SI 19, TH 22, GB 12, GB 21.
- **Facial nerve paralysis:** ST 7, TH 17, plus points that address specific nerve branch involved.

Evidence-Based Applications

- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders**, prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[1]
- Case series reported that electroacupuncture at GB 14, SI 18, ST 7, GB 20, and LI 4 was effective treatment for **peripheral facial paralysis.**[2]
- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18,

TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[3]

- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with **Sjögren's syndrome.**[4]
- Acupuncture at LI 4, ST 6, ST 7, and TH 17 was superior to placebo for the prevention of **postoperative dental pain.**[5,6]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 6, ST 7, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[7]
- Acupuncture at ST 7 significantly changed the blood flow to kidney, brain, and heart, as well as to the ipsilateral masseter muscle. The local increase in masseteric blood flow likely works through largely a peripheral mechanism. Increasing **organ blood flow** through the needling of ST 7 suggests that a central mechanism is at work.[8]

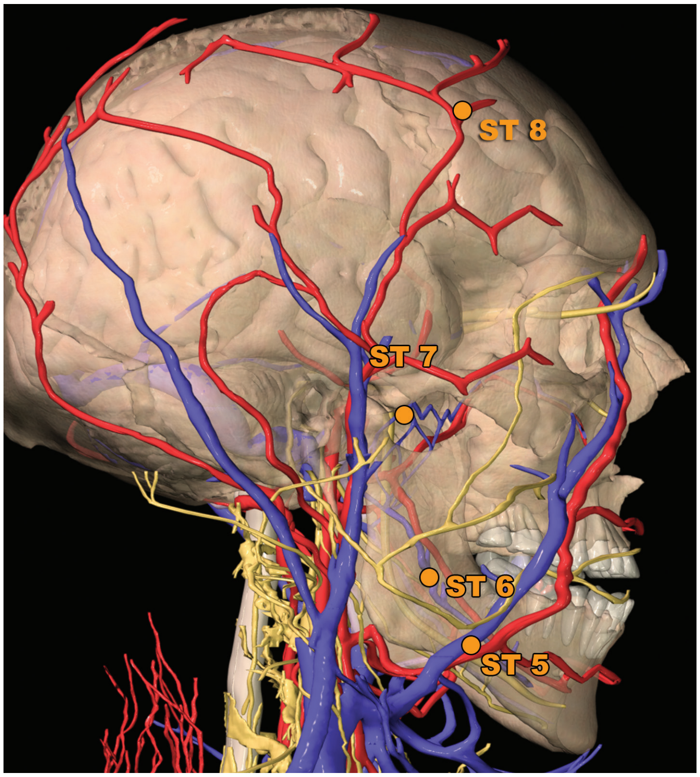

Figure 3-22. The transparent skull layer illustrates several usually hidden intracranial arteries and veins. The inferior alveolar artery and vein course medial to the mandible and connect ST 5 and ST 6. The maxillary artery leaves the external carotid artery and meanders toward the eye ventral to ST 7. The superficial temporal artery, the smaller terminal branch of the external carotid, begins within the parotid gland, coursing behind the neck of the mandible, crossing the zygomatic process of the temporal bone, and then dividing into a frontal and parietal branch. ST 8 lands along the parietal branch.

ST 8

Tou Wei "Head Corner"

Directly above ST 7, 0.5 cun within the anterior hairline at the corner of the forehead, 4.5 cun from the midline, in line with GB 13, GB 15, BL 3, BL 3, and GV 24.

Bone

- **Coronal suture:** This cranial suture, a dense and fibrous connective tissue joint, defines the border between the frontal and parietal bones of the skull. Cranial sutures may allow movement of the cranial bones, depending upon the age, species, and health of the individual. Unossified sutures allow compensatory movements of cranial bones in relation to loads placed on the skull, thereby helping absorb the impact of mechanical forces placed upon it.[2]

Clinical Relevance: Sutures may become tender with cranial dysfunction and benefit from localized treatment with acupuncture or related techniques.

Muscles

- **Temporalis muscle:** The temporalis muscle arises from the temporal fossa and deep part of the temporal fascia. When the temporalis muscle contracts, it retrudes (moves backward) the mandible and elevates it (closes the mouth). The temporalis muscle originates in the temporal fossa between the inferior temporal line of the parietal bone and the infratemporal crest. It inserts on the coronoid (anterior prong) of the mandible as well as the anterior ramus.

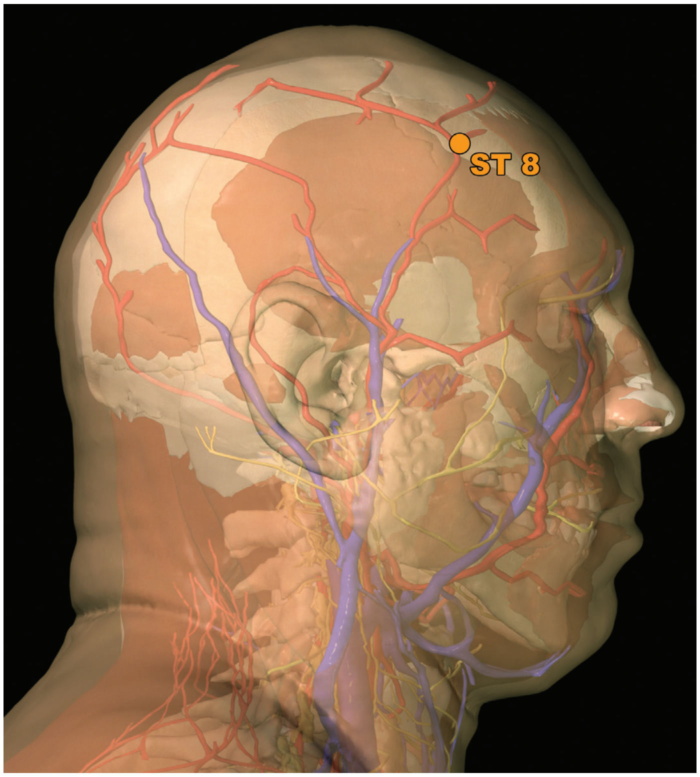

Figure 3-23. The intersecting temporal and anterior hairlines define the "Head Corner" of ST 8.

Clinical Relevance: The temporalis muscle causes myogenic head pain, diffuse jaw pain, and referred pain to the teeth, eyebrow/frontal sinus, and ear. As shown in Figure 3-23, ST 8 lands along the attachment site of the temporalis muscle to the skull, thereby qualifying as an attachment trigger point of sorts. Since myofascial dysfunction of the temporalis may provoke migraine, ST 8 may aid in its treatment.[3]

Nerves

- **Deep temporal nerves (CN V_3):** These branches of the mandibular division of the trigeminal nerve supply motor function to the temporalis muscle.
- **Zygomaticotemporal nerve, from maxillary nerve CN V_2:** One of the branches of the zygomatic nerve, along with the zygomaticofacial nerve. Supplies the skin over the zygomatic arch and anterior temporal area. Postsynaptic parasympathetic fibers from the pterygopalatine ganglion travel with this nerve to the lacrimal nerve.
- **Auriculotemporal nerve from the mandibular nerve (CN V_3):** Conveys postsynaptic parasympathetic secretomotor fibers to the parotid gland, provides sensation to the auricle, external acoustic meatus, external surface of the tympanic membrane, and the skin superior to the auricle.
- **Temporal branches of facial nerve (CN VII):** Supplies the auricularis superior and auricularis anterior muscles, the frontal belly of the occipitofrontalis muscle, and the superior part of the orbicularis oculi muscle.

Clinical Relevance: The nerves in the vicinity of ST 8 impact a variety of functions including mastication, facial expression, scalp and facial sensation, and local autonomic supply to the eye. This multiplicity of neural activities explains the benefits of ST 8 for frontal headache, migraine, dizziness, and referred pain.

Vessels

- **Superficial temporal artery:** a branch of the external carotid artery, supplying the scalp and temporal regions.
- **Superficial temporal veins:** This widespread network drains the scalp and zygomatic arch.

Clinical Relevance: A mass in the lateral forehead and temporal fossa should not be needled, as it could represent a pseudoaneurysm of the superficial temporal artery, especially with a history of recent blunt trauma or surgery to the forehead.[4] Do not needle a mass in this region.

Indications and Potential Point Combinations

- **Frontal headache:** ST 8, GB 14, GV 24.5.
- **Migraine:** ST 8, GB 5, GB 20, GV 14, LU 7.
- **Dizziness:** ST 8, GB 20, BL 10; or Jiaji points from C1-C4, Taiyang, and ST 8.[5]

ST 9

Ren Ying “Man’s Pulse” or “Man’s Prognosis”

On the anterior border of the sternocleidomastoid muscle, level with the laryngeal prominence, over the common carotid artery.

Note: Avoid puncturing the common carotid artery and the adjacent internal jugular vein (IJV). Deep needling and injury to the major vessels in this region could lead to death. Needle superficially or between the artery and the lateral border of the thyroid cartilage, which places the needle tip medial to the common carotid, rather than in the rich venous territory on its lateral aspect. That is, the IJV lies lateral to the common carotid artery and should be avoided, as illustrated in Figure 3-28. Furthermore, electrical stimulation over this area, i.e., in the vicinity of the carotid body or the vagus nerve in the anterior triangle of the neck could cause bradycardia due to the rich autonomic supply serving this region.[1]

Muscles

- **Platysma muscle:** Helps depress mandible and participates in the grimace expression.
- **Sternocleidomastoid (SCM) muscle:** Tilts head in a lateral direction. Flexes and rotates the neck so that the face turns up and to the opposite side. When activated bilaterally, the SCM flexes the neck and thrusts the chin forward.
- **Omohyoid muscle:** Acts on the hyoid bone to depress, retract, and steady it.

Clinical Relevance: Muscle tension in this region can lead to referred pain and craniofascial somatic dysfunction.[6] Myofascial restriction in the SCM accompanies several pain problems, including headache and temporomandibular disorders (TMD).[7,8] Trigger points in the SCM refer to the ear, the back of the head, the vertex, the chin, the forehead, the cheek, and angle of the mandible, the TMF, and the eye. Tension in the omohyoid can cause transient swelling in the caudal neck during deglutition.[9] This occurs when the fascial attachment of the intermediate tendon of the omohyoid muscle weakens, leading to pseudodysphagia.[10] That said, the locus of ST 9 gears its indications more toward somatoautonomic effects instead of myofascial, given its position on the medial border of the SCM.

Nerves

- **Facial nerve, cervical branch (CN VII):** Innervates the platysma

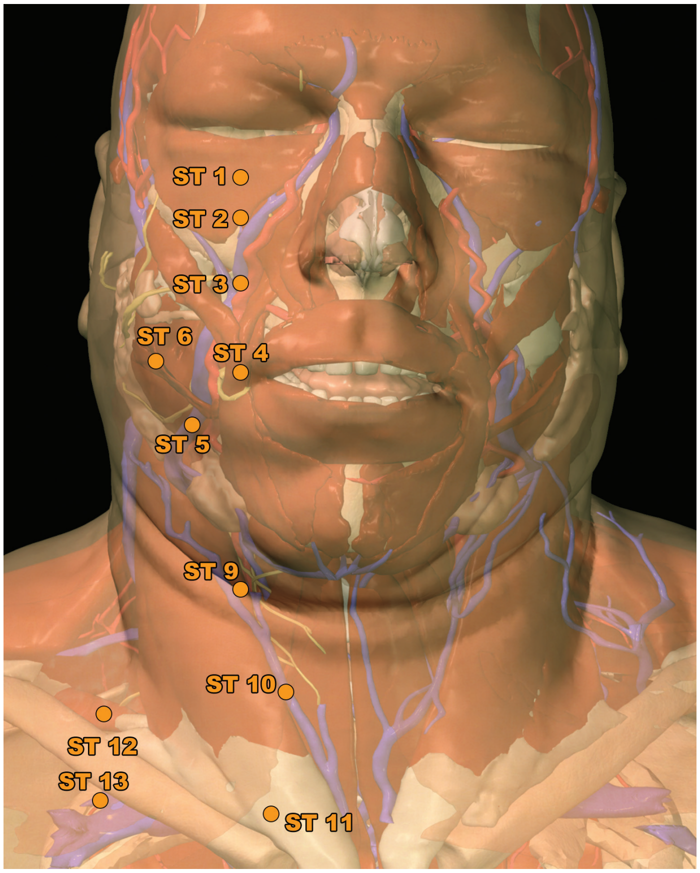

Figure 3-25. The semi-transparent skin in this image allows visualization of the anatomical relationships between ST 1-6 and ST 10-13. Note their close vascular relationships with the facial artery and vein (most notably ST 2-ST 5), the jugular vessels (ST 9, ST 10), and the subclavian vein (ST 12, ST 13).

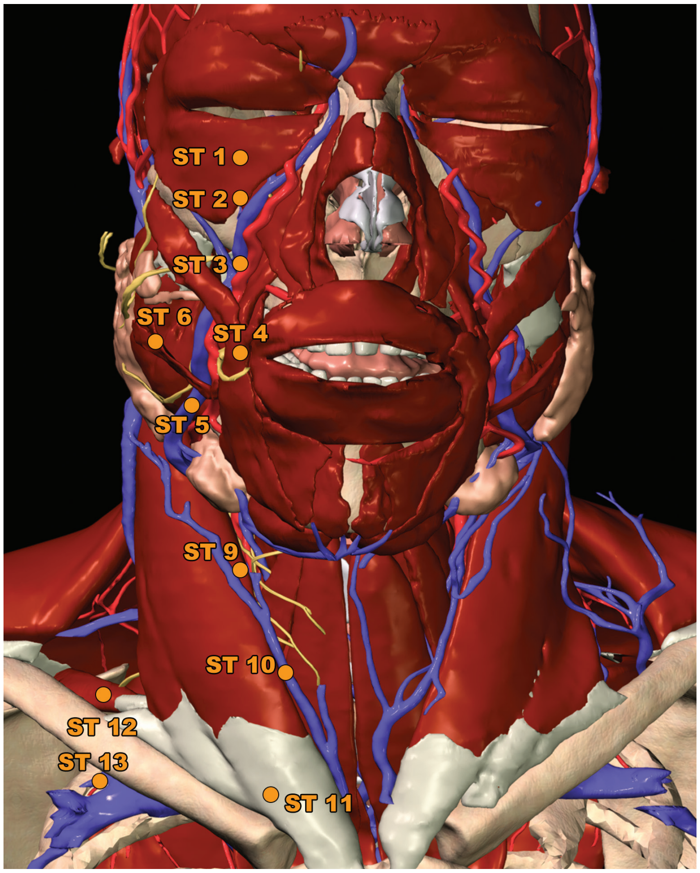

Figure 3-26. Both ST 9 and ST 10 are located along the anterior border of the SCM over the carotid artery. Ancient practitioners would assess pulse quality here as one of the nine locations palpated in the course of pulse diagnosis. Quirico, *in Teaching Atlas of Acupuncture. Volume 2: Clinical Indications,* Thieme, p. 24, notes that of these nine locations, three belonged to the sky, three to man, and three to the earth. ST 9, also called “Man’s Pulse” corresponded to the “man” position and occupied the middle position of the three “man” pulses.

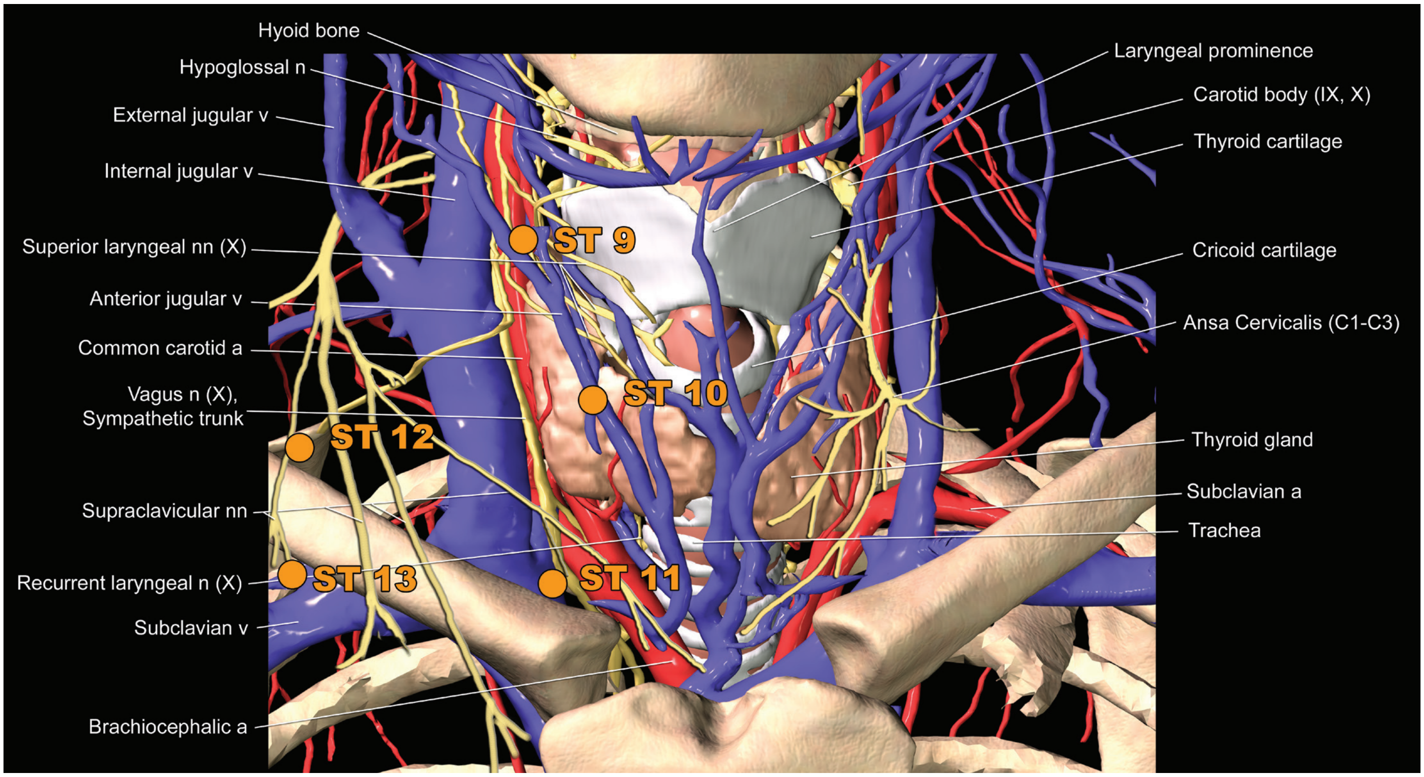

Figure 3-27. ST 9 - ST 13 live within rich neurovascular territory on the anterior neck. Note specifically the relationship between ST 9 (shown only on the right) and the carotid body (only seen on the left). The carotid body senses blood oxygen and carbon dioxide levels as well as pH and temperature. In the face of low circulating oxygen tension, the carotid body initiates a reflex that increases cardiac rate, blood pressure, and the respiratory rate and inspiratory depth. No wonder ST 9 is so often included in protocols for respiratory difficulty, hypertension, and related conditions. Too, the proximity of ST 9 with the superior laryngeal nerve territory explains its application in laryngeal disorders.

muscle. The facial nerve communicates with the transverse cervical nerve, thereby creating a faciocervical anastomosis ventral or caudal to the submandibular gland and sometimes within the parotid gland.[11]

- **Transverse cervical nerve (C2, C3):** Supplies the skin of the anterior triangle.[2]

- **Ansa cervicalis (C1-C3 motor fibers):** A nerve loop that supplies the infrahyoid muscles in the anterior cervical triangle. The ansa cervicalis provides donor tissue for neural reconstruction and restoration of function for the vocal cords in cases of recurrent laryngeal nerve paralysis.[12] Iatrogenic injuries to the ansa cervicalis may occur during surgical procedures such as arytenoid adduction and thyroplasty.

- **Vagus nerve (CN X):** Sensory to the inferior pharynx, larynx, thoracic organs, abdominal organs; taste sensation from the root of the tongue and taste buds on the epiglottis; motor supply to the soft palate, pharynx, the palatoglossus muscle, and the intrinsic laryngeal muscles (which are responsible for phonation); proprioceptive to the aforementioned musculature; parasympathetic supply to the thoracic and abdominal viscera.

- **Sympathetic trunk (C8-T5):** The sympathetic trunks in the neck are associated with three cervical sympathetic ganglia (superior, middle, and inferior) which receive presynaptic fibers from the superior thoracic spinal nerves and associated white rami communicantes via the sympathetic trunk. From these ganglia, postsynaptic fibers pass to splanchnic nerves to the spinal nerve in the cervical region via gray rami communicantes, or they proceed as direct visceral branches, or splanchnic nerves. Sympathetic branches destined to reach the head and neck viscera travel with the arteries (vertebral and carotid) and their branches. Although the cervical sympathetic trunk lies interior to the carotid sheath within the prevertebral fascia and one would not needle this location for acupuncture, neuromodulation in this vicinity does influence autonomic function.

- **Carotid body:** Supplied by the carotid sinus nerve (CN IX). This cluster of chemoreceptors and supporting cells located at the carotid artery bifurcation monitors arterial oxygen and carbon dioxide levels. It senses changes in pH and temperature as well. In response to low blood oxygen levels, the chemoreceptors trigger an increase in the rate and depth of respiration, heart rate, and blood pressure. Feedback about blood chemistry travels to cardiorespiratory centers in the medulla oblongata (brainstem) through CN IX afferent branches. The medullary cardiorespiratory centers integrate carotid body messages with signals from aortic body chemoreceptors through vagal nerve afferents. Centers such as the rostral ventrolateral medulla (RVLM) coordinate changes in respiration and blood pressure as a result of the converging input from somatic and autonomic fibers.

Clinical Relevance: At ST 9, the facial nerve supplies only the superficial muscular layer constituting the platysma muscle. However, the facial nerve communicates with several cranial nerves including the all three divisions of the trigeminal nerve (CN V), as well as CN VIII, CN IX, and CN X. It also links to branches of the cervical plexus including the great auricular, the greater and lesser occipital, and transverse cervical nerves.[13] These connections may have clinical ramifications as the body adapts to nerve injury and alternate routes of nerve communication develop. In terms of acupuncture, the somatic afferent stimulation provided by

needling may deliver a stronger and more widespread neurologic effect through interneural connections such as these involving the facial nerve. Medical acupuncture may also promote recovery of other regional nerve function, including the ansa cervicalis.

Far and away, however, the main clinical impact of ST 9 pertains to its autonomic influence over blood pressure and hemodynamics and local somatic influences over pharyngeal and laryngeal functions.

Vessels

- **Superior thyroid artery:** Supplies the thyroid gland. Originates beneath the anterior border of the SCM, branches into the hyoid (infrahyoid) artery, the SCM artery, the superior laryngeal artery, and the cricothyroid artery.
- **Anterior jugular vein:** Arises near the hyoid bone as the superficial submandibular veins join, and drains into either the external jugular vein or subclavian vein. This valveless vein communicates with its contralateral companion and connect by means of a transverse trunk called the venous jugular arch. The trunk receives tributaries from the inferior thyroid veins which also communicate with the internal jugular vein.
- **Internal jugular vein (IJV):** Usually the largest vein in the neck, the IJV receives blood from the brain (through the inferior petrosal sinus and sigmoid sinus), anterior face, deep cervical muscles, and cervical viscera (i.e., thyroid and parathyroid glands, larynx and trachea, and the pharynx and esophagus). The retromandibular, facial, and lingual veins likewise drain into the IJV. As shown in Figure 3-28, the right IJV is usually larger than the left, and sits a bit apart from the common carotid artery, whereas the left IJV overlaps the common carotid.

Clinical Relevance: The relatively superficial placement of the IJV's and their lack of body "armor" (e.g., bone or cartilage) makes these large and vital vessels more vulnerable to damage. An acupuncture needle too deeply placed can cause quick and significant loss of blood, leading to hypovolemic shock and patient death if left untreated. Ninety-five percent of the body's blood passes through the IJV. Aside from the safety hazards of deeply needling ST 9, cautious and appropriate placement supports neuromodulation and regulation of blood pressure. In addition, indirect benefits to the thyroid gland from neuromodulation of the vessels and nerves supplying it may hold value in thryoid disorders, though this is not yet supported by evidence.

Indications and Potential Point Combinations

- **Pharyngitis, tonsillitis, dysphonia, aphasia, vocal cord problems:**[3] ST 9, LI 10, LU 7, CV 22, CV 23.
- **Thyroid support:** ST 9, CV 22, CV 23, ST 36.

Evidence-Based Applications

- ST 9 (along with LU 7, KI 6, SI 3, and BL 60) significantly improved **dysphonias** associated with benign vocal pathologies.[4]
- Case series showed effectiveness of ST 9 for **trigeminal neuralgia**, along with "adjuvant points" along trigeminal nerve branches.[5]

ST 10

Shui Tu "Water Prominence"

On the anterior border of the sternocleidomastoid muscle, midway between ST 9 and ST 11. (This is the access point used in anesthesia for stellate ganglion block).

Gland

- **Lateral lobe of the thyroid gland:** The body's largest endocrine gland, producing thyroid hormone (which controls metabolic rate) and calcitonin (which controls calcium metabolism).

Clinical Relevance: Releasing fascial restrictions around the thyroid gland may improve blood flow and neural signaling, possibly improving thyroid health.

Cartilage

- **Cricoid cartilage:** A complete ring of cartilage between the larynx and trachea that provides attachments for various muscles, cartilages, and ligaments.

Clinical Relevance: Freeing up the local connective tissue fosters better function of the myriad structures that attach to the cricoid.

Muscles

- **Platysma muscle:** Helps depress mandible and participates in the grimace expression.
- **Sternocleidomastoid (SCM) muscle:** Tilts head in a lateral direction. Flexes and rotates the neck so that the face turns up and to the opposite side. When activated bilaterally, the SCM flexes the neck and thrusts the chin forward.
- **Omohyoid muscle:** Acts on the hyoid bone to depress, retract, and steady it.
- **Sternohyoid muscle:** After the hyoid bone has been elevated during swallowing, the sternohyoid muscle then depresses the hyoid bone.
- **Sternothyroid muscle:** Depresses the larynx and hyoid bone. Surgeons may incise the sternothyroid muscle in order to remove the thyroid. Sternothyroid division may cause post-operative pain and possibly non-neurogenic dysphonia, as the strap musculature may contribute to voice production, though evidence is mixed.[1,2]

Clinical Relevance: The extrinsic laryngeal strap muscles include the sternohyoid, sternothyroid, and omohyoid muscles; they supply vertical motion to the larynx, important for phonation, yawning, respiration, singing, and swallowing.[3] Acupuncture at ST 10 may benefit patients with dysphonia by helping normalize muscle tension in the infrahyoid musculature.

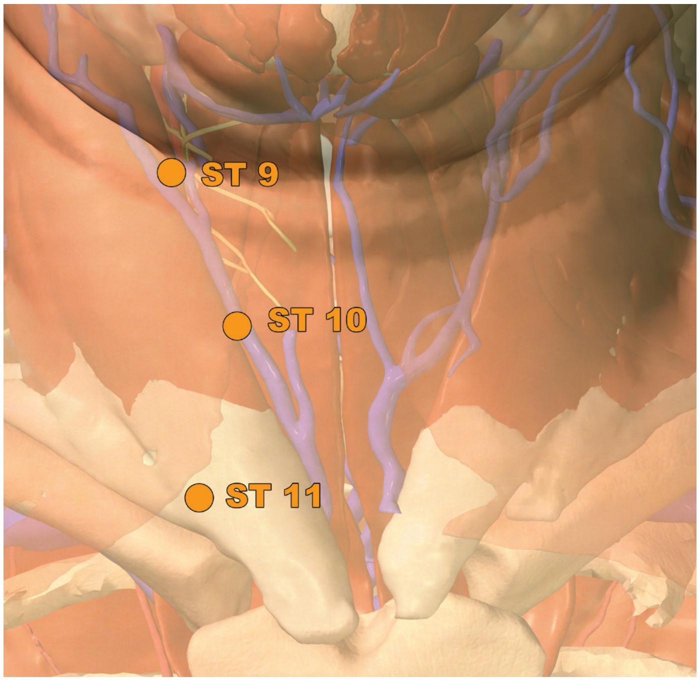

Figure 3-29. The ST points on the anterior neck all relate to the SCM and roughly follow the jugular veins.

Nerves

- **Facial nerve, cervical branch (CN VII):** Innervates the platysma muscle.
- **Transverse cervical nerve (C2, C3):** Supplies the skin of the anterior triangle.
- **Ansa cervicalis (C1-C3 motor fibers):** A nerve loop that supplies the infrahyoid muscles in the anterior cervical triangle, including the sternothyroid muscle.
- **Vagus nerve (CN X):** Sensory to the inferior pharynx, larynx, thoracic organs, abdominal organs; taste sensation from the root of the tongue and taste buds on the epiglottis; motor supply to the soft palate, pharynx, the palatoglossus muscle, and the intrinsic laryngeal muscles (which are responsible for phonation); proprioceptive to the aforementioned musculature; parasympathetic supply to the thoracic and abdominal viscera.
- **Recurrent laryngeal nerve (from CN X):** Provides sensory innervation to the larynx inferior to the glottis, as well as motor supply to the larynx. The recurrent laryngeal nerve may be injured during surgery; patients may suffer transient or long-term voice changes. The nerve courses on the dorsolateral surface of the trachea.
- **Spinal accessory nerve (CN XI):** Innervates the SCM and trapezius muscles.
- **Sympathetic trunk (C8-T5):** The sympathetic trunks in the neck are associated with three cervical sympathetic ganglia (superior, middle, and inferior) which receive presynaptic fibers from the superior thoracic spinal nerves and associated white rami communicantes via the sympathetic trunk. From these ganglia, postsynaptic fibers pass to splanchnic nerves to the spinal nerve in the cervical region via gray rami communicantes, or they proceed as direct visceral branches, or splanchnic nerves. Sympathetic branches destined to reach the head and neck viscera travel with the arteries (vertebral and carotid).
- **Stellate ganglion:** Also known as the cervicothoracic or inferior cervical ganglion, this sympathetic ganglion represents a fusion of the inferior cervical and first thoracic ganglia. Located at C7, ventral to the C7 transverse process and neck of the first rib, the stellate ganglion sits just caudal to the subclavian artery. Though several centimeters superficial to the stellate ganglion, stimulation of ST 10 through acupuncture, massage, or laser

Figure 3-31. The descriptive term for ST 10, "Water Prominence", designates the place where one can palpate the carotid artery, like a "gentle splash of water". (Ellis A, Wiseman N, and Boss K. Grasping the Wind. Brookline, MA: Paradigm Publications, 1989. P. 65.) Note the anatomical proximity of ST 10 to several large vessels in the ventral cervical region as well as the thyroid gland, the trachea, and the recurrent largyngeal nerve (not shown) that courses along the trachea's dorsolateral aspect.

therapy has the potential to neuromodulate local autonomic structures, including the stellate ganglion.

Clinical Relevance: States of sympathetic hyperarousal may respond to blockade, sympathectomy, or other neuromodulatory interventions such as acupuncture and related techniques. For this reason, conditions such as Raynaud's phenomenon, hyperhydrosis (extreme sweating) of the hands, and post-traumatic stress disorder (PTSD)[4] may respond to activation of ST 10. Proximity of the recurrent laryngeal nerve to ST 10 justifies its inclusion in needling protocols for dysphonia.

Vessels

- **Anterior jugular vein:** Arises near the hyoid bone as the superficial submandibular veins join, and drains into either the external jugular vein or subclavian vein.
- **Internal jugular vein (IJV):** Usually the largest vein in the neck, the IJV receives blood from the brain, anterior face, deep cervical muscles, and cervical viscera.
- **Common carotid artery:** Ascends within the carotid sheath, along with the internal jugular vein and vagus nerve. Divides into the internal and external arteries at the level of the superior border of the thyroid cartilage.

Clinical Relevance: Presence of several large vessels within reach of ST 10 warrants caution.

Indications and Potential Point Combinations

- **Pharyngitis:** ST 10, LI 10, LI 11.
- **Goiter:** ST 10, ST 9, CV 22, CV 23
- **Dysphonia:** ST 10, ST 9, CV 22, CV 23, LI 4, LU 7

ST 11

Qi She "Qi Abode"

At the superior border of the sternal end of the clavicle, between the sternal and clavicular heads of the sternocleidomastoid muscle.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1] (Note the relationship between ST 11 and the lung in Figure 3-33.) An anatomical study of the acupuncture safety of ST 11 and CV 22 revealed that the needle tip may injure the pleural cupula, large local veins, and the vagus nerve.[2]

Gland

- **Inferior aspect of the thyroid gland:** The body's largest endocrine gland, producing thyroid hormone (which controls metabolic rate) and calcitonin (which controls calcium metabolism).

Clinical Relevance: As the "Qi Abode", ST 11 lives close to anatomical structures that give deeper insight into the ancient Chinese view of "Qi". Not as metaphysical energy, but as intersecting blood vessels ferrying dissolved gases (oxygen, carbon dioxide), nutrients, and in this case, hormones synthesized by the thyroid. Witness the vascular expressway in Figure 3-32 and note the presence of the vagus nerve and sympathetic trunk as well, making its way into the thoracic cage.

Muscles

- **Platysma muscle:** Helps depress mandible and participates in the grimace expression.
- **Sternocleidomastoid (SCM) muscle:** Tilts head in a lateral direction. Flexes and rotates the neck so that the face turns up and to the opposite side. When activated bilaterally, the SCM flexes the neck and thrusts the chin forward.
- **Sternohyoid muscle:** After the hyoid bone has been elevated during swallowing, the sternohyoid muscle then depresses the hyoid bone.
- **Sternothyroid muscle:** Depresses the larynx and hyoid bone.

Clinical Relevance: The extrinsic laryngeal strap muscles include the sternohyoid, sternothyroid, and omohyoid muscles; they supply vertical motion to the larynx, important for phonation, yawning, respiration, singing, and swallowing.[3] Acupuncture at ST 10 may benefit patients with dysphonia by helping normalize muscle tension in the infrahyoid musculature. Massage, acupuncture or other neuromodulatory approaches may improve the appearance of the anterior neck through its effects on the platysma muscle.

Trigger points in the SCM may refer to the sternum (CV 22, CV 21, CV 20 territory), the angle of the mandible, the chin, the occiput, the vertex, the TMJ, the cheek, and the eyebrow and frontal sinus zones.

Nerves

- **Facial nerve, cervical branch (CN VII):** Innervates the platysma muscle.
- **Transverse cervical nerve (C2, C3):** Supplies the skin of the anterior triangle.
- **Ansa cervicalis (C1-C3 motor fibers):** A nerve loop that supplies the infrahyoid muscles in the anterior cervical triangle.
- **Medial branch of the supraclavicular nerve (C3, C4):** Supplies the skin of this portion of the neck. See below for further discussion on the supraclavicular nerves.
- **Supraclavicular nerves (C3, C4):** Supply the skin of the neck, cranioventral thorax, and and shoulder. The supraclavicular nerve, a strictly sensory structure, arises from the superficial cervical plexus and divides into medial, intermediate, and lateral branches. The medial branch, closest to ST 11, courses caudal to the SCM to the clavicle where it crosses the platysma to provide sensation to the sternal notch. The intermediate branches travels along the lateral border of the SCM and continues in a caudal direction past the medial third of the clavicle. It then traverses the platysma muscle to reach the skin of the cranioventral thorax. The lateral branch meanders over the pectoralis major muscle and anterior part of the deltoid toward the second rib and scapular spine. However, three anatomic variants

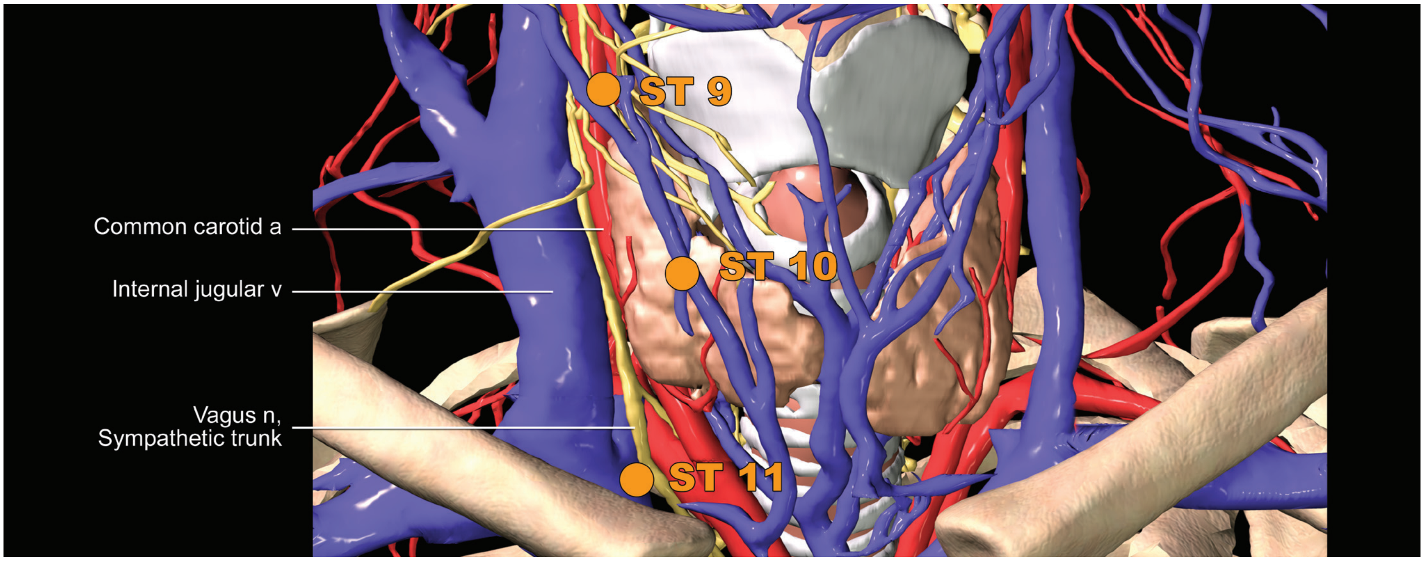

Figure 3-32. The applications for ST 11 resemble those of ST 9 and ST 10, given shared neurovascular anatomy. This figure highlights its proximity to the vagus nerve and sympathetic trunk.

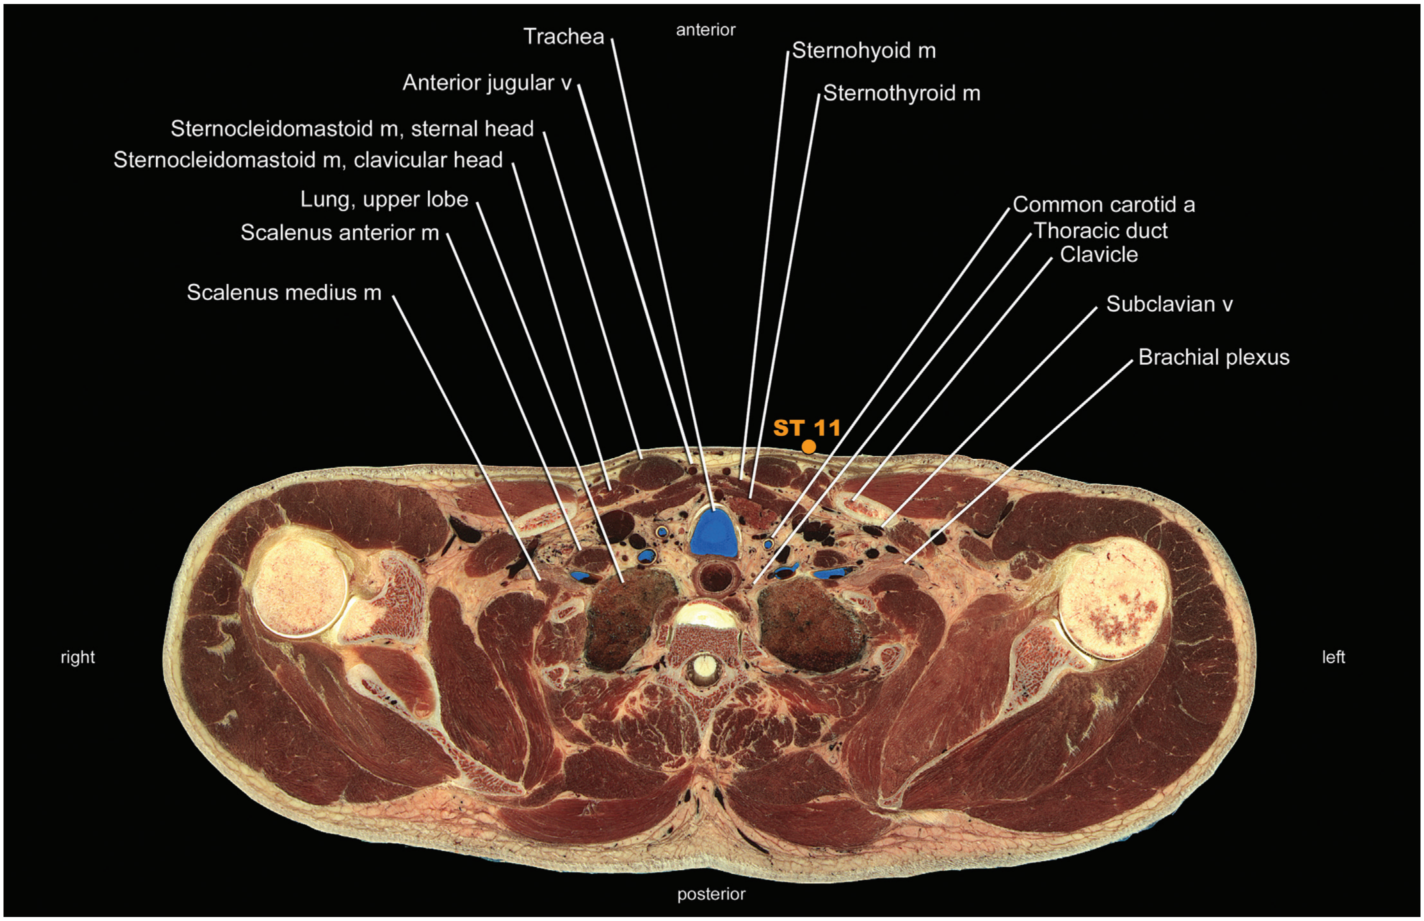

Figure 3-33. The cross section shows the superficial muscular and deeper neurovascular layers beneath ST 11. Note that deep needling of ST 11 might injure not only major vessels, but it also the lung, leading to pneumothorax.

pose the possibility of nerve entrapment of the supraclavicular nerve.[4] Sources of compression include fibrous bands, muscles, tendons, or bone. Identification of the source of entrapment may require computed tomography, but neuropathic pain and non-bony sources of compression may respond to acupuncture.

- **Vagus nerve (CN X):** Sensory to the inferior pharynx, larynx, thoracic organs, abdominal organs; taste sensation from the root of the tongue and taste buds on the epiglottis; motor supply to the soft palate, pharynx, the palatoglossus muscle, and the intrinsic laryngeal muscles (which are responsible for phonation); proprioceptive to the aforementioned musculature; parasympathetic supply to the thoracic and abdominal viscera.
- **Phrenic nerve (C3-C5):** Supplies motor, sympathetic and sensory information for the thoracic diaphragm. Also supplies the mediastinal pleura and pericardium.

Clinical Relevance: The proximity of ST 11 to the vagus nerve and sympathetic trunk highlights the effects of ST 11 on the autonomic nervous system (see Figure 3-32). Deep needling of ST 11 may injure the phrenic nerve. Pain in the sternomanubrial region may respond to neuromodulation of the medial branch of the supraclavicular nerve if the nerve is suffering entrapment.

Vessels

- **Anterior jugular vein:** Arises near the hyoid bone as the superficial submandibular veins join, and drains into either the external jugular vein or subclavian vein.
- **Internal jugular vein (IJV):** Usually the largest vein in the neck, the IJV receives blood from the brain, anterior face, deep cervical muscles, and cervical viscera.
- **Common carotid artery:** Ascends within the carotid sheath, along with the internal jugular vein and vagus nerve. Divides into the internal and external arteries at the level of the superior border of the thyroid cartilage.

Clinical Relevance: Superficial needling of ST 11 will affect mostly the platysma, sternohyoid and sternothyroid muscles as illustrated in the cross section of Figure 3-33. However, several large veins lurk beneath this layer, warranting caution with needling.

Indications and Potential Point Combinations

- **Neck pain or restriction related to the SCM:** ST 11, ST 10, ST 12, GB 20.
- **Hypertension:** ST 9, ST 11, LI 4, ST 36.

ST 12

Que Pen (ancient Chinese word for supraclavicular fossa)[1]

"Empty (or Broken) Basin"

On the supraclavicular fossa, at the midclavicular line, approximately 4 cun lateral to the midline.

Note: On the left side, ST 12 coincides with Virchow's node, also called a "signal" or "sentinel" lymph node. Finding an enlarged, firm lymph node here warrants suspicion of metastasis of a malignancy in the thorax or abdomen.

ST 12 is also one of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) where deep needling can cause pneumothorax.[2] Needling deeply behind the clavicle may traumatize the subclavian vessels or the lung.

Muscles

- **Platysma muscle:** Helps depress mandible and participates in the grimace expression.

Clinical Relevance: Easing myofascial restrictions of the platysma muscle at its attachment onto the scapula may assist in an acupressure/acupuncture facelift. Pressure here may also benefit neck pain with anterior tension.

Nerves

- **Facial nerve, cervical branch (CN VII):** Innervates the platysma muscle.
- **Supraclavicular nerves (C3, C4):** Supply the skin of the neck, cranioventral thorax, and and shoulder. The supraclavicular nerve, a strictly sensory structure, arises from the superficial cervical plexus and divides into medial, intermediate, and lateral branches. The medial branch, closest to ST 11, courses caudal to the SCM to the clavicle where it crosses the platysma to provide sensation to the sternal notch. The intermediate branches travels along the lateral border of the SCM and continues in a caudal direction past the medial third of the clavicle. It then traverses the platysma muscle to reach the skin of the cranioventral thorax. The lateral branch meanders over the pectoralis major muscle and anterior part of the deltoid toward the second rib and scapular spine. However, three anatomic variants pose the possibility of nerve entrapment of the supraclavicular nerve.[4] Sources of compression include fibrous bands, muscles, tendons, or bone. Identification of the source of entrapment may require computed tomography, but neuropathic pain and non-bony sources of compression may respond to acupuncture.
- **Supraclavicular branches of brachial plexus:** Includes the dorsal scapular nerve (C5, possibly also C4; supplies the rhomboid muscles); the long thoracic nerve (C5-C7; supplies the serratus anterior muscle); the nerve to the subclavius (C5, possibly C4 and C6; supplies the subclavius muscle); and the suprascapular nerve (C5, C6, possibly C4; supplies the supraspinatus and infraspinatus muscles; articular branches supply the glenohumeral joint and joint capsule).
- **Phrenic nerve (C3-C5):** Supplies motor, sympathetic and sensory information for the thoracic diaphragm. Also supplies the mediastinal pleura and pericardium.

Clinical Relevance: Deep needling of ST 12 or ST 11 may injure the phrenic nerve and result in respiratory distress.[5] In Figure 3-35, note the location of the left phrenic nerve, not far from where ST 12 would land (shown here only on the right side of the body).

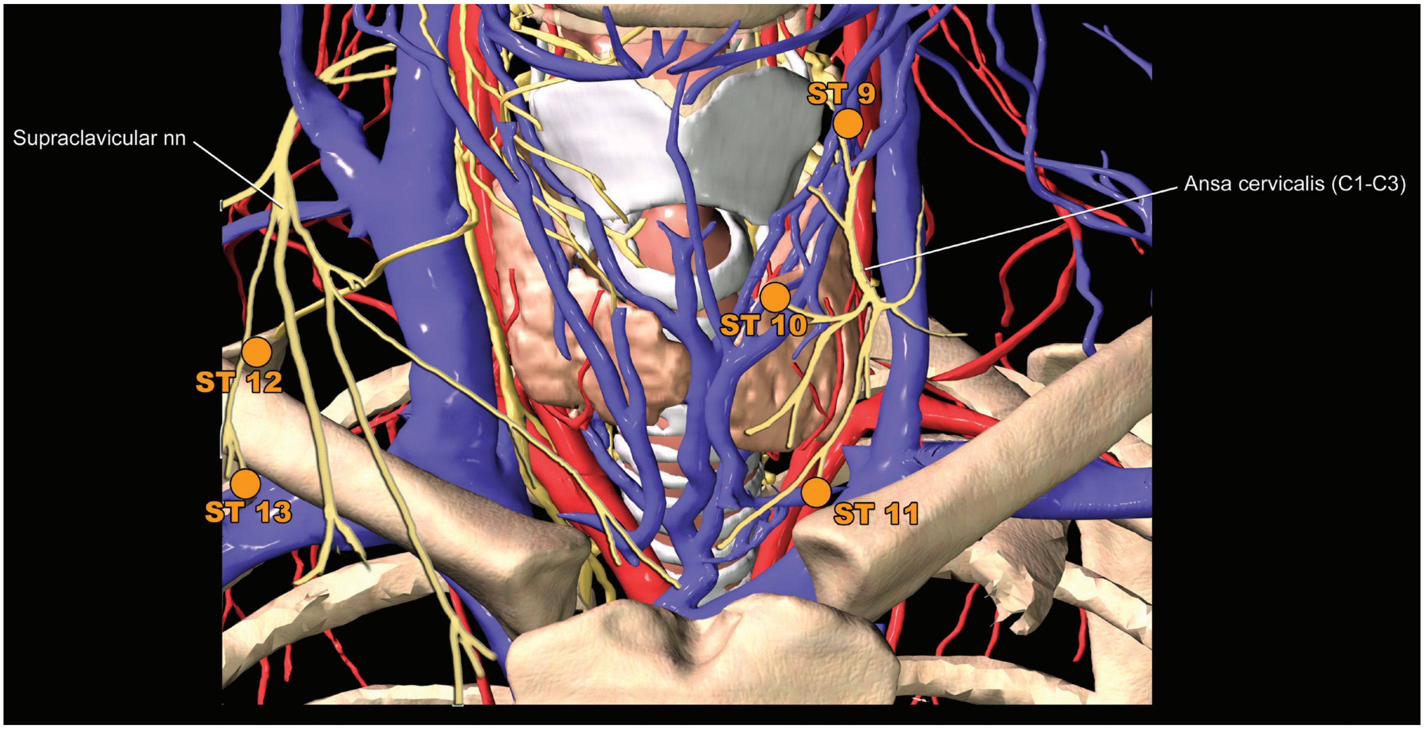

Figure 3-34. The name "Empty Basin" for ST 12 refers to the supraclavicular fossa, that forms behind the clavicle. This image reveals the relationship between the supraclavicular nerve branches and ST 11, ST 12, and ST 13. Clinical applications of these acupuncture points include myofascial restriction causing entrapment syndromes.

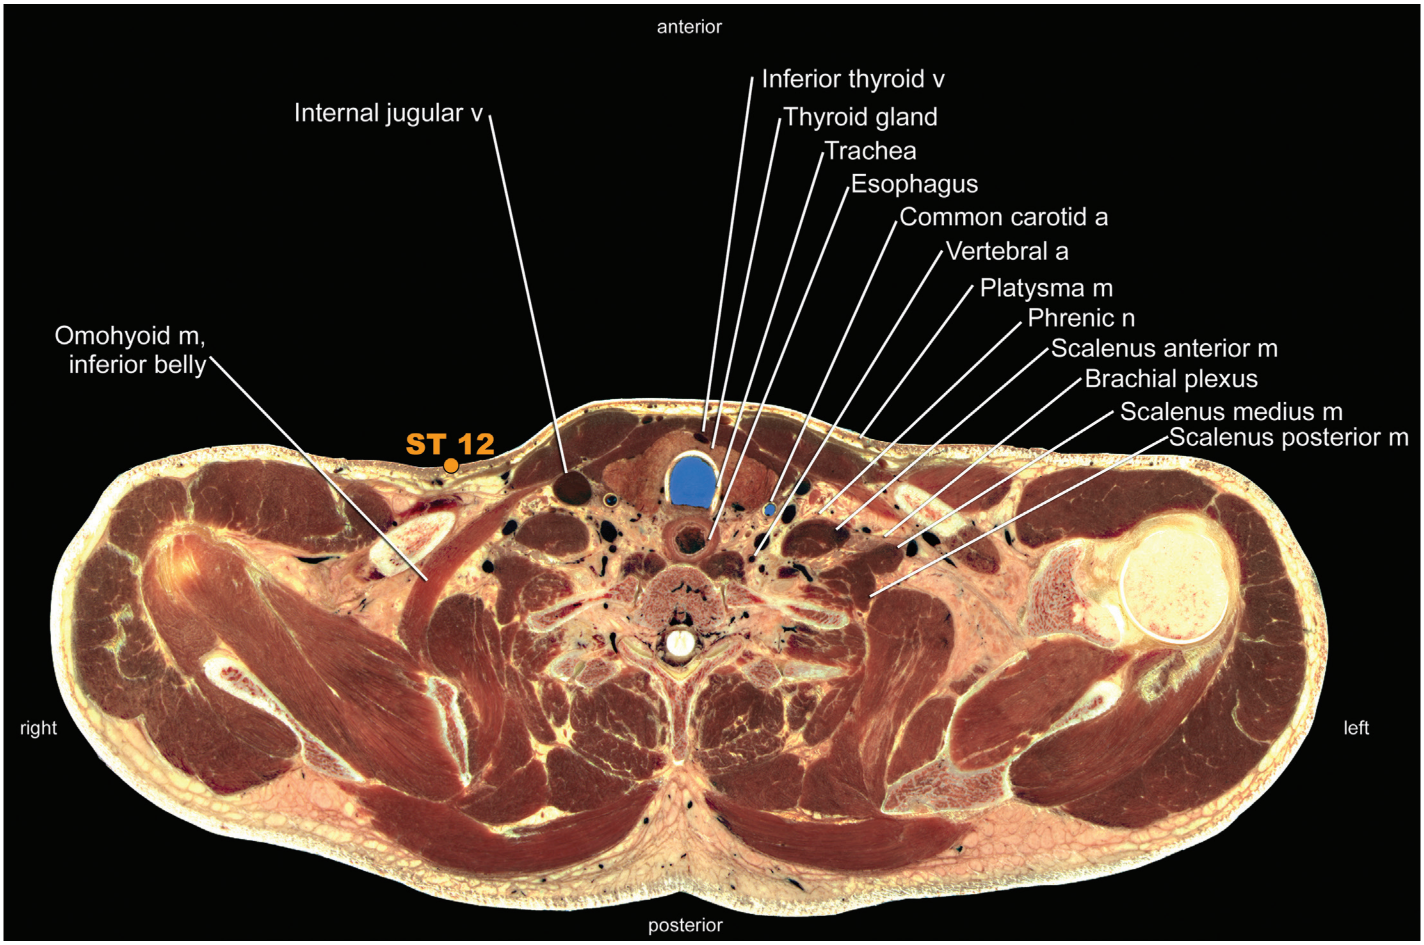

Figure 3-35. This cross section reveals the vital neurovascular structures within reach of a needle entering ST 12. This emphasizes the need for caution as well as portrays opportunities to influence respiratory function and blood supply to the head and neck.

Vessels

- **Transverse cervical artery:** Also known as transverse artery of the neck; originates from the thyrocervical trunk, which is a branch of the subclavian artery. The artery sends branches to muscles in the posterior cervical triangle, and the trapezius and rhomboid muscles. It crosses the phrenic nerve and anterior scalene muscle at nearly a 90 degree angle, 2-3 cm above the clavicle and then passes through the brachial plexus trunks, to which it supplies vasa nervorum. Damage to the transverse cervical artery may lead to adherence between the phrenic nerve and vessel. This may then cause vascular compression of the phrenic nerve following traumatic or iatrogenic injuries, including chiropractic manipulation of the neck. If this occurs, the patient may experience paralysis of the thoracic diaphragm.[6]
- **Suprascapular artery (from thyrocervical trunk):** Supplies muscles on the posterior scapula.

Clinical Relevance: Freeing myofascial restriction of the local vasculature may improve diaphragmatic excursion if mechanical compression from tissue adherence is resulting in phrenic nerve dysfunction.

Indications and Potential Point Combinations

- **Pain in supraclavicular fossa, supraclavicular nerve entrapment:**[3] ST 12, ST 13, LI 17.
- **Neck pain:** ST 12, ST 11, GB 21 acupressure.[7]
- **Shoulder pain involving the clavicle:** ST 12, ST 13, LI15, TH 14, LU 1, local trigger points.

ST 13

Qi Hu "Qi Door"

On the inferior border of the clavicle, along the midclavicular line, directly inferior to ST 12.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (clavicular part):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The clavicular head flexes the humerus, whereas the sternocostal head extends the humerus once it is flexed.
- **Subclavius muscle:** Depresses and anchors the clavicle, which helps stabilize it during arm movements.

Clinical Relevance: Tension in these structures flexes the upper back ventrally and rounds the shoulders. Releasing restriction facilitates fuller range of motion and better posture. Trigger points in the clavicular section of the pectoralis major muscle refer strongly to the deltoid and shoulder. Trigger points in the subclavius muscle, small as the structure is, refer along the caudal clavicle, along the biceps and the radial aspect of the antebrachium to the palmar surface of the first three digits of the hand. The trajectory of the subclavius referred pain pattern resembles the LU channel course.

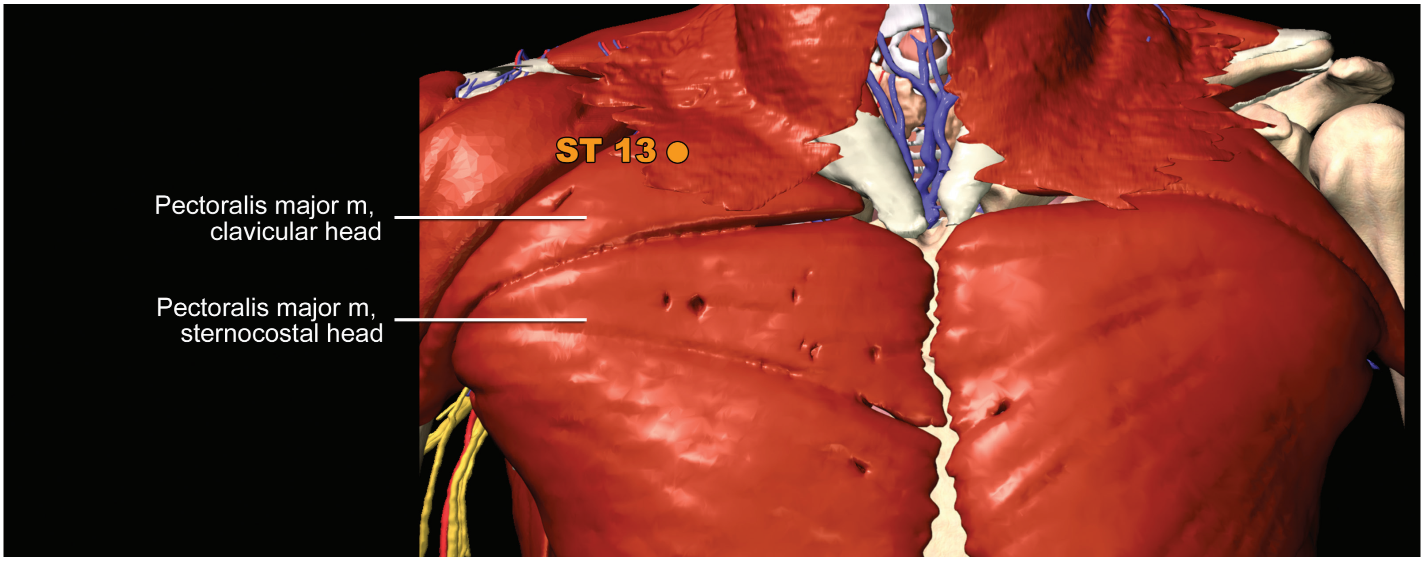
Nerves

- **Supraclavicular nerves (C3, C4):** Supply the skin of the neck, cranioventral thorax, and and shoulder. The supraclavicular nerve, a strictly sensory structure, arises from the superficial cervical plexus and divides into medial, intermediate, and lateral branches. The medial branch, closest to ST 11, courses caudal to the SCM to the clavicle where it crosses the platysma to provide sensation to the sternal notch. The intermediate branches travels along the lateral border of the SCM and continues in a caudal direction past the medial third of the clavicle. It then traverses the platysma muscle to reach the skin of the cranioventral thorax. The lateral branch meanders over the pectoralis major muscle and anterior part of the deltoid toward the second rib and scapular spine. However, three anatomic variants pose the possibility of nerve entrapment of the supraclavicular nerve.[2] Sources of compression include fibrous bands, muscles, tendons, or bone. Identification of the source of entrapment may require computed tomography, but neuropathic pain and non-bony sources of compression may respond to acupuncture. ST 13 affects the intermediate branches of the supraclavicular nerves.
- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head.
- **Nerve to the subclavius (C5 and C6):** Supplies the subclavius muscle.

Clinical Relevance: Entrapment of the nerves coursing through this region may irritate the axons and predispose the muscles to chronic pain and tension, stemming from neuropathic abnormalities.

Vessels

- **Thoracoacromial artery:** Supplies the breast and clavipectoral region.
- **Subclavian artery:** Supplies the arm, neck, and brain.



ST 13
Pectoralis major m, clavicular head
Pectoralis major m, sternocostal head

Figure 3-36. ST 13 lies inferior to the clavicle, atop the subclavius muscle. This muscle shortens with a "hunched up" or rounded shouldered position. This posture may be acquired from habit, work type, or organic causes of structural dysfunction. For example, patients with Scheuermann's disease (spinal osteochondrosis; juvenilekyphoscoliosis) may experience thoracic outlet syndrome/brachial plexopathy and migraine headache. The myofascial basis for these secondary afflictions relates to the thoracic kyphosis produced by this condition. Shortening of the anterior shoulder girdle musculature can lead to costoclavicular venous compression and brachial plexopathy. While acupuncture in this region will not reverse the spinal abnormalities, relaxing the regional muscle tension around these structures may offset the vascular compromise. That is, by relaxing the subclavius muscle, this will lessen compression of the subclavian vein against the anterior scalene muscle on the first rib. (Collins JD, Saxton EH, Miller TQ, et al. Scheuermann's disease as a model displaying the mechanism of venous obstruction in thoracic outlet syndrome and migraine patients: MRI and MRA. *J Natl Med Assoc.* 2003;95:298-306.)

Venae comitantes of axillary a
Basilic v
Brachial a

Figure 3-38. The Chinese name for the point ST 13, "Qi Door", bespeaks its location near the source for Qi as vital air, the lung.

- **Subclavian vein:** Joins with the internal jugular vein to form the brachiocephalic vein, a union called the "venous angle." This is where, on the left side, the thoracic duct drains lymph into the venous circulation; on the right side, the right lymphatic duct drains the lymph.

Clinical Relevance: Compressive myofascial restriction limits blood flow, facilitating neural sensitization and cultivating trigger point dysfunction.

Indications and Potential Point Combinations

- **Thoracic outlet syndrome:** ST 13, ST 12, ST 11, GB 21, LI 17. Local trigger points.
- **Supraclavicular nerve entrapment syndrome:** ST 11, ST 12, ST 13, local trigger points.

ST 14

Ku Fang “Storehouse” or “Storeroom”

In the first intercostal space on the midclavicular line. To find the first intercostal space, locate the sternal angle. This will link to the second rib. The first intercostal space lies above the second rib.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (clavicular or sternocostal head):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The clavicular head flexes the humerus, whereas the sternocostal head extends the humerus once it is flexed.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: Trigger points in the pectoralis muscle refer to the deltoid from the clavicular section and to the left breast/pectoral region and medial elbow from the sternocostal section. Tension in the region of the first and second ribs increases the likelihood of nerve entrapment and brachial plexopathy. Note the nerves and vessels coursing beneath ST 14 in Figure 3-39. The muscles in this region shorten when an individual recruits the accessory muscles of inspiration, or AMI (e.g., the pectoralis and trapezius muscles). This occurs when the demand for oxygen exceeds the pumping ability of the thoracic diaphragm. Patients with chronic obstructive pulmonary disease (COPD) and asthma often utilize their AMI. Intense exercise also activates the AMI; their muscle contraction coincides with that of the diaphragm during inspiration.[2]

Nerves

- **Intermediate and lateral supraclavicular nerves (C3, C4):** Supply the skin over the shoulder and clavicle.
- **Supraclavicular nerves (C3, C4):** Supply the skin of the neck, cranioventral thorax, and and shoulder. The supraclavicular nerve, a strictly sensory structure, arises from the superficial cervical plexus and divides into medial, intermediate, and lateral branches. The medial branch, closest to ST 11, courses caudal to the SCM to the clavicle where it crosses the platysma to provide sensation to the sternal notch. The intermediate branches travels along the lateral border of the SCM and continues in a caudal direction past the medial third of the clavicle. It then traverses the platysma muscle to reach the skin of the cranioventral thorax. The lateral branch meanders over the pectoralis major muscle and anterior part of the deltoid toward the second rib and scapular spine. However, three anatomic variants pose the possibility of nerve entrapment of the supraclavicular nerve.[3] Sources of compression include fibrous bands, muscles, tendons, or bone. Identification of the source of entrapment may require computed tomography, but neuropathic pain and non-bony sources of compression may respond to acupuncture. ST 14 affects the lateral branches of the supraclavicular nerves.
- **Ventral ramus of the 1st intercostal nerve:** The superior part of the ventral ramus joints the brachial plexus, whereas the inferior part becomes the 1st intercostal nerve. Supplies the local skin and musculature.
- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head.

Clinical Relevance: Tension in the upper thoracic musculature limits blood and oxygen delivery to local nerve supply. This perpetuates trigger point dysfunction and pain.

Vessels

- **Thoracoacromial artery and vein:** Supplies and drains, respectively, the breast and clavipectoral region.
- **1st anterior intercostal artery (from internal thoracic artery):** Distributes to intercostal muscles, the overlying skin, and the parietal pleura.

Clinical Relevance: Reduced blood supply from muscle tension and connective tissue fibrosis reduces arterial blood supply and venous and lymphatic drainage. This can compromise health of the regions supplied, including breast health.

Indications and Potential Point Combinations

- **Use if tender for relieving sadness and stress of an emotional shock:** ST 14, CV 17, HT 7.
- **Lung or bronchial problems: bronchitis, dyspnea, fullness and pain in the chest, cough, COPD:** ST 14, LU 1, LU 2, BL 13, BL 23.

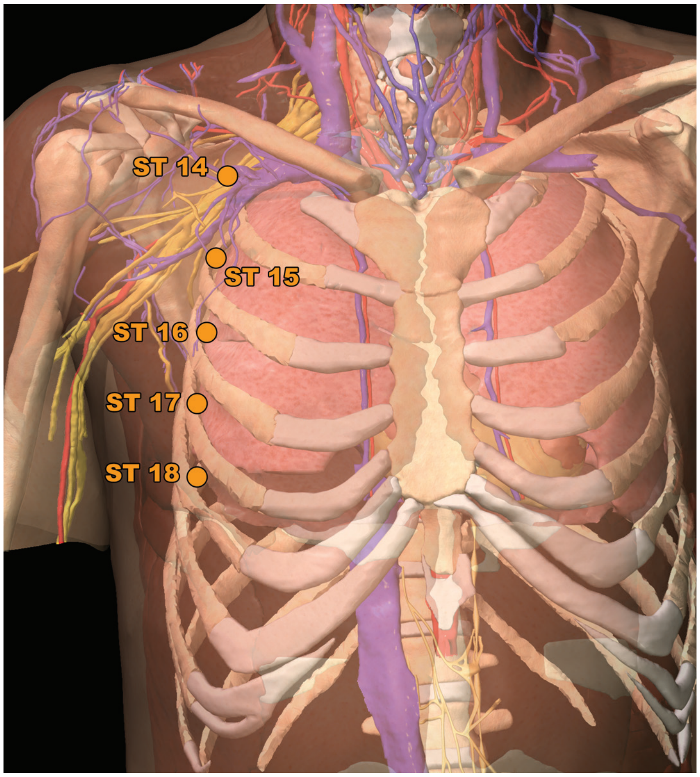

Figure 3-39. Treatment of myofascial restrictions and other sources of somatic dysfunction at ST 14 may improve movement of the thoracic cage. That is, by reducing tension in the pectoralis major, an accessory muscle of inspiration, a fuller incursion of air may result. This explains the point’s descriptive title, “Storehouse” of Qi (meaning vital air).

Figure 3-40. The centrality of the ST 14 atop the pectoralis major becomes apparent here. Note the location of the subclavius muscle deep to the pectoralis, as well as the adjacent pool of venous blood in the subclavian and the nearby brachial plexus.

- **Local pain:** ST 14 and other pectoralis major trigger points.

ST 15

Wu Yi "Room Screen" or "Roof"

On the pectoral region, in the second intercostal space, on the midclavicular line. To find the second intercostal space, locate the sternal angle. This will indicate the level of the second rib.

The second intercostal space lies below the second rib. One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (sternocostal head):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The clavicular head flexes the humerus, whereas the sternocostal head extends the humerus once it is flexed.
- **Pectoralis minor muscle:** By drawing the scapula anteriorly and inferiorly against the thoracic wall, the pectoralis minor muscle helps stabilize the scapula.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: The muscles in this region shorten when an individual recruits the accessory muscles of inspiration, or AMI (e.g., the pectoralis and trapezius muscles). This occurs when the demand for oxygen exceeds the pumping ability of the thoracic diaphragm. Patients with chronic obstructive pulmonary disease (COPD) and asthma often utilize their AMI. Intense exercise also activates the AMI; their muscle contraction coincides with that of the diaphragm during inspiration.

Trigger points in the pectoralis major muscle, sternocostal head, refer to the breast region, the medial brachium, medial elbow, and ulnar aspect of the hand, palmar surface, echoing the Heart (HT) and Pericardium (PC) channels. Pectoralis minor trigger points refer diffusely over the entire pectoral region, the deltoid muscle, and the medial brachium, ulnar surface of the antebrachium, and ulnar aspect of the palm and fingers, reminiscent as well of the PC and HT channels, like the pectoralis major muscle.

Nerves

- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head. The medial pectoral nerve (C8, T1) innervates the pectoralis minor muscle.
- **T2 intercostal nerve:** Supplies the local skin and musculature.

Clinical Relevance: Deactivating trigger points in the shoulder and upper thoracic region in the vicinity of ST 15 and nearby locations may help "disinhibit" the chest and reduce thoracic tension, from both emotional and physical etiologies.

Vessels

- **Thoracoacromial artery:** Supplies the breast and clavipectoral region.
- **Second anterior intercostal artery (from internal thoracic artery):** Distributes to intercostal muscles, the overlying skin, and the parietal pleura.

Clinical Relevance: Local vessels supply and drain the breast and nearby region. Normal circulation supports healthy tissue.

Indications and Potential Point Combinations

- **Lung or bronchial problems: Bronchitis, dyspnea, allergic manifestations, fullness and pain in the chest, cough:** ST 15, CV 17, BL 13, LU 7.
- **Somatic pain in the cranial thorax:** ST 15, other local trigger points in the pectoral and upper back region, CV 17.

References

Figure 3-42. This cross section shows how ST 15 rests on the chest like a roof over the lungs, true to its name, “Room Screen”. That is, the pectoralis major and minor together form a substantial roof over the lungs in this well-muscled individual.

ST 16

Ying Chuang "Breast (or Chest) Window"

In the third intercostal space, midclavicular line. To find the third intercostal space, locate the sternal angle. This will link to the second rib. The second intercostal space lies below the second rib; the third intercostal space is one space below.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (sternocostal head):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The sternocostal head extends the humerus once it is flexed.
- **Pectoralis minor muscle:** By drawing the scapula anteriorly and inferiorly against the thoracic wall, the pectoralis minor muscle helps stabilize the scapula.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: Myofascial dysfunction in the pectoral muscles refer to the breast, deltoid, and medial arm, ulnar aspect of the antebrachium, and ulnar aspect of the palm as well as the middle, ring, and pinkie fingers.

Nerves

- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head.
- **T3 intercostal nerve:** Supplies the local skin and musculature.

Clinical Relevance: Trigger point dysfunction in the cranial thoracic musculature may make the nerves in supplying the local tissues to become neuropathic, causing pain and further tension.

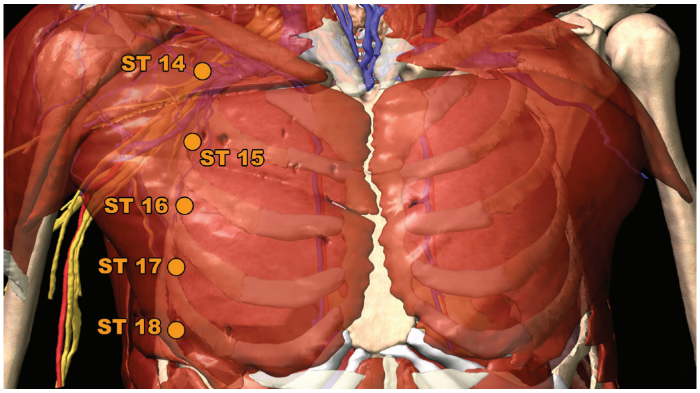

Figure 3-43. The transparent musculature in this image demonstrates the relationship of ST 16 to the third intercostal space and overlying pectoralis major muscle. The name "Chest Window" or "Breast Window", ST 16 connotes an entryway into either the breast or the lung itself. In the past, needling this site with an acupuncture needle may have promoted fuller respiration or lactation, thereby earning this point a reputation for benefiting breathing and milk let-down. Direct needling of the breast is less common with modern approaches.

Vessels

- **Thoracoacromial artery:** Supplies the breast and clavipectoral region.
- **Third anterior intercostal artery:** From the internal thoracic artery; supplies the intercostal muscles, overlying skin, and parietal pleura.

Indications and Potential Point Combinations

- **Intercostal pain, pectoralis trigger point: ST 16, other local tender points. Consider BL outer line points at same intercostal level.**

References

1. Lee WM, Leung HB, and Wong WC. Iatrogenic bilateral pneumothorax arising from acupuncture: a case report. *Journal of Orthopaedic Surgery.* 2005;13(3):300-302.

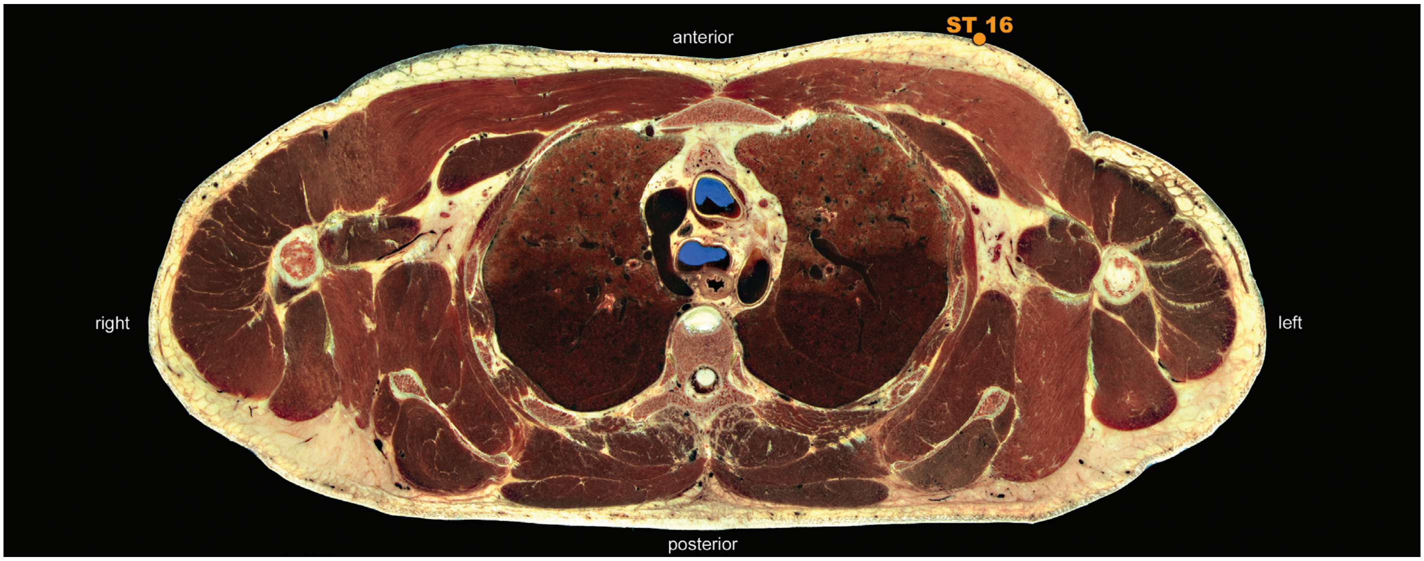

Figure 3-44. ST 16 sits upon the breast, which is not frequently needled. If attempting to deactivate a pectoralis trigger point, one should remain cognizant of the thickness of breast tissue that the needle must traverse. It would be wise to determine whether another method of resolving pectoralis tension (e.g., indirect needling or massage) might offer a better and safer approach.

ST 17

Ru Zhong "Breast Center"

On the pectoral region, in the fourth intercostal space, on the midclavicular line. In most males this location coincides with the nipple.

Acupuncture and moxibustion contraindicated.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (sternocostal head):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The clavicular head flexes the humerus, whereas the sternocostal head extends the humerus once it is flexed.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: Trigger points in the myofascial tissue deep to the breast are best approached with non-needle methods, given that needling through the nipple is not advised.

Nerves

- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head.
- **T4 intercostal nerve:** Supplies the local skin and musculature.

Clinical Relevance:

Vessels

- **Fourth anterior intercostal artery (from internal thoracic artery):** Distributes blood to the intercostal muscles, the overlying skin, and the parietal pleura.

Indications and Potential Point Combinations

- **This point serves as a landmark on the chest to determine the location of other points; it is not meant for needling.**

References

1. Lee WM, Leung HB, and Wong WC. Iatrogenic bilateral pneumothorax arising from acupuncture: a case report. *Journal of Orthopaedic Surgery.* 2005;13(3):300-302.

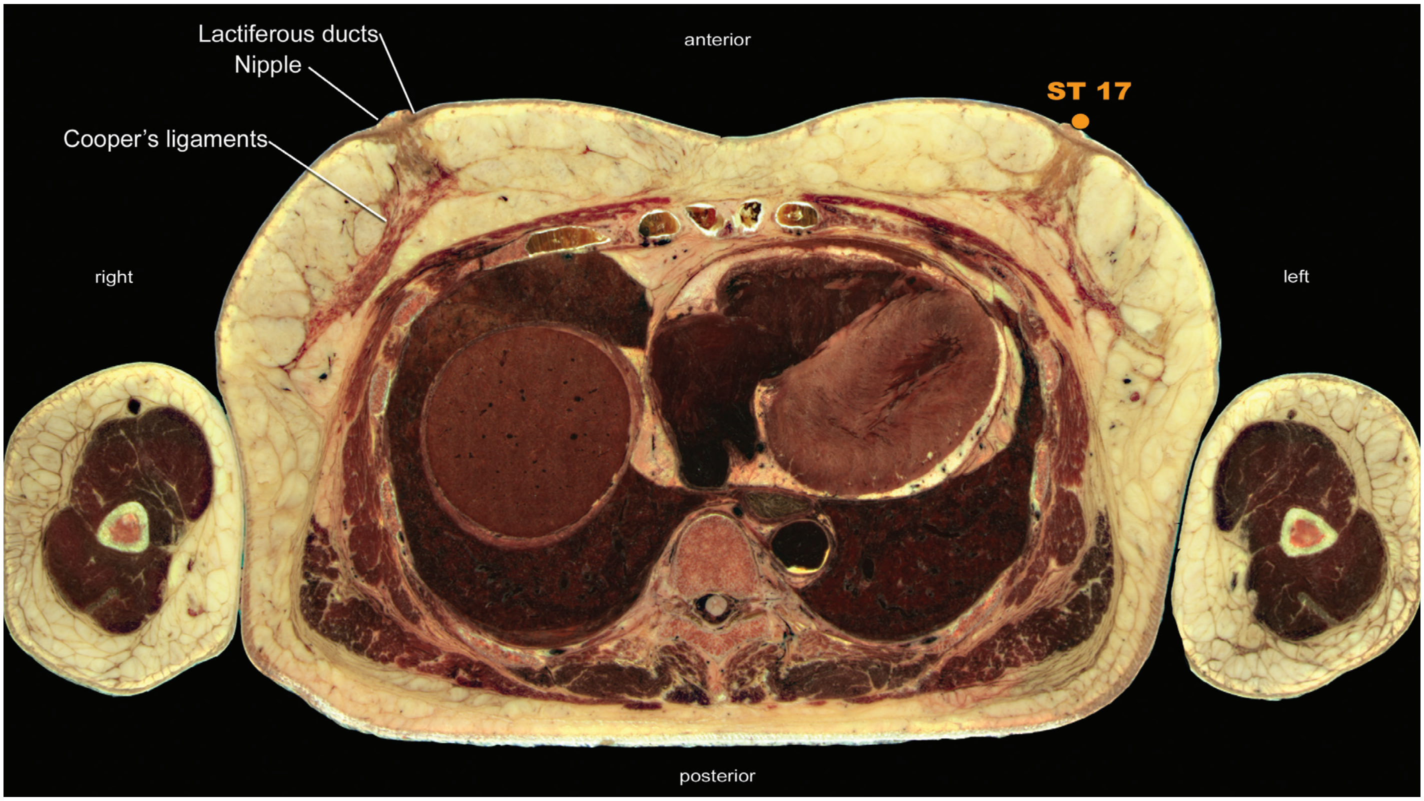

Figure 3-45. In this cross section from the Visible Woman, ST 17 centers on the nipple, explaining its name, "Breast Center". ST 17 serves as a landmark only, forbidden to needle.

ST 18

Ru Gen "Breast Root"

In the fifth intercostal space on the midclavicular line.

One of several acupuncture points (i.e., LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Pectoralis major muscle (sternocostal head):** The pectoralis powerfully adducts the arm and medially rotates the humerus. The clavicular head flexes the humerus, whereas the sternocostal head extends the humerus once it is flexed.
- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation.
- **External intercostal muscle:** Elevates the ribs.
- **Internal intercostal muscle:** Depresses the ribs.

Clinical Relevance: ST 18 lives at a busy intersection of muscular attachments where the pectoralis muscle terminates and the rectus abdominis begins. As such, patients may experience various pulls and twists below the breast and mistake pain in this vicinity as cardiogenic. Although pain in this area may indeed originate in the heart, stomach, other organs or myofascia, the latter should be included in the differential diagnosis.

Nerves

- **T5 intercostal nerve:** Supplies the local skin and musculature.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.
- **Lateral and medial pectoral nerves:** Supply the pectoralis major; the C5 and C6 portions innervate the clavicular head, whereas C7, C8, and T1 supply the sternocostal head.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery and vein:** Arises from the internal thoracic artery and vein to supply and drain the upper portion of the rectus abdominis muscle. Anastomose with the inferior epigastric artery and vein.
- **Fifth anterior intercostal artery and vein (from internal thoracic artery and vein):** Distributes to intercostal muscles, the overlying skin, and the parietal pleura.

Clinical Relevance: Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic, these superficial vessels on the abdominal wall provide collateral pathways for circulation.

Indications and Potential Point Combinations

- **Mastitis, problems with lactation:** ST 18, CV 17, SI 1.
- **Thoracic pain:** Locate source, ST 18 if tender or along dysfunctional intercostal segment. BL 15, BL 44, BL 14, BL 43, BL 16, BL 45.
- **Respiratory conditions:** cough, asthma: If rib cage restrictions prohibit full diaphragmatic excursion, palpate for trigger points and muscle tension; ST 18 if tender, along with associated regional trigger points, LI 4, ST 36, LU 7, GV 14, BL 13, ST 13.

Evidence-Based Indications

- A randomized, controlled clinical trial evaluated the effects of catgut embedded into acupuncture points for **"mammary gland hyperplasia"** in humans, as compared to an herbal patent medicine. Points employed were ST 18, ST 15, CV 17, SP 10, ST 36, and GB 34. The researchers reported value in acupuncture reducing hyperplastic lump size.[3]

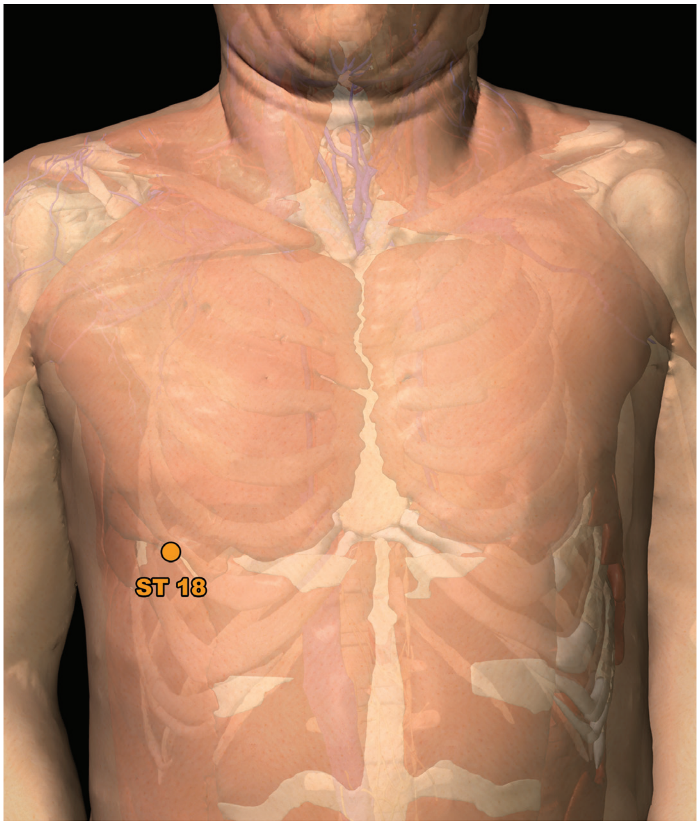

Figure 3-46. As the name "Breast Root" denotes, ST 18 resides below the breast, at its caudal "root".

Figure 3-47. ST 18 stimulation impacts several muscles involved in respiration; with overwork or cough, they may become tense and compress nerves coursing between and through the various layers. Muscles associated with respiration include the rectus abdominis, the external oblique, the diaphragm, and the serratus anterior muscles. Note the various slips of muscles underlying ST 18. The point's proximity to the breast supports its indications for mastitis and lactation disorders. Note, as well, that a deeply penetrating acupuncture needle at ST 18 on the right side of the body could enter the liver. ST 18 on the left lives close to the actual stomach organ, the channel's namesake.

ST 19

Bu Rong "Not Contained"

Immediately inferior to the costal arch, 6 cun above the umbilicus. Approximately 2 cun lateral to the anterior midline. In the rectus abdominis muscle, midway between its lateral border (linea semilunaris) and the linea alba. Level with CV 14 and KI 21.

Note: Deep needling may result in organ puncture.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation. Like the muscles in the cheek on the face, the rectus abdominis does not lie on any supportive skeletal structure. This lack of bony attachment makes the rectus abdominis vulnerable to sudden strains, as occur with coughing, straining to defecate, and sitting upright from a supine position.[1] The rectus abdominis can expand and contract up to nine of an individuals finger-breadths.
- **External oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels or cause somato-visceral discomfort such as a sense of abdominal fullness, nausea, and vomiting. Rectus abdominis myofascial dysfunction can be caused by internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can also produce visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery and vein:** Arises from the internal thoracic artery and vein to supply and drain the upper portion of the rectus abdominis muscle. Anastomose with the inferior epigastric artery and vein.

Clinical Relevance: Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic, these superficial vessels on the abdominal wall provide collateral pathways for circulation.

Indications and Potential Point Combinations

- **Problems with the diaphragm, esophagus, or upper digestive function: Nausea, vomiting, abdominal pain and distension, reflux esophagitis, hiatal hernia, poor appetite: ST 19, CV 12, CV 17, PC 6, ST 36.**

Structures that share overlapping spinal cord segments possess neuroanatomic relationships capable of causing somatovisceral and viscerosomatic reflexes between acupuncture points on the trunk and internal organs.

ST 20

Cheng Man "Supporting (or Assuming) Fullness"

On the abdomen, 5 cun above the umbilicus, approximately 2 cun lateral to the anterior midline, in the rectus abdominis muscle, midway between its lateral border (linea semilunaris) and the linea alba. Level with CV 13 and KI 20.

Note: Deep needling may result in organ puncture.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation. Like the muscles in the cheek on the face, the rectus abdominis does not lie on any supportive skeletal structure. This lack of bony attachment makes the rectus abdominis vulnerable to sudden strains, as occur with coughing or sitting upright from a supine position.[1]
- **External oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery and vein:** Arises from the internal thoracic artery and vein to supply and drain the upper portion of the rectus abdominis muscle. Anastomose with the inferior epigastric artery and vein.
- **Inferior epigastric artery and vein:** Terminal medial branch of the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath.

Rupture of the inferior epigastric artery following coughing episodes can cause acute abdominal pain and rectus sheath hematoma.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or

Figure 3-52. The anatomy and indications for ST 20 resemble those of ST 19, based on their similar cranial abdominal locations. This cross section emphasizes the need for caution in needling, as deeply inserting needles over the abdomen may enter internal organs. For example, note the rather superficial location of the transverse colon in the left medial hemi-abdomen.

anticoagulant therapy increases the risk.[3] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[4]

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

Indications and Potential Point Combinations

- **Problems with the diaphragm, esophagus, or upper digestive function:** Nausea, vomiting, abdominal pain and distension, reflux esophagitis, hiatal hernia, poor appetite: ST 19, CV 12, CV 17, PC 6, ST 36.
- **Cranial abdominal wall discomfort:** ST 20, KI 20, CV 13, BL 20, BL 49 and local trigger points; modify according to level(s) of involvement.

Evidence-Based Applications

- Acupuncture at LU 7, ST 40, GB 20, and GV 20, as well as plum-blossom hammer tapping at GV 14, alleviated vertigo and related symptoms in a majority of patients in a case series of patients with **vertebrobasilar ischemic vertigo.**[5]

ST 21

Liang Men "Beam Gate"

On the abdomen, 4 cun above the umbilicus, approximately 2 cun lateral to the anterior midline, in the rectus abdominis muscle, midway between its lateral border (linea semilunaris) and the linea alba. Level with CV 12 and KI 19.

Note: Deep needling may result in organ puncture.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation. Like the muscles in the cheek on the face, the rectus abdominis does not lie on any supportive skeletal structure. This lack of bony attachment makes the rectus abdominis vulnerable to sudden strains, as occur with coughing or sitting upright from a supine position.[1]
- **External oblique muscle**: Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves. See Figure 3-55 to examine the abdominal wall in cross section at the locus of ST 21.

Vessels

- **Superior epigastric artery and vein:** Arises from the internal thoracic artery and vein to supply and drain the upper portion of the rectus abdominis muscle. Anastomose with the inferior epigastric artery and vein.
- **Inferior epigastric artery and vein:** Terminal medial branch of the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath.

Rupture of the inferior epigastric artery following coughing episodes can cause acute abdominal pain and rectus sheath hematoma.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[3] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[4]

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

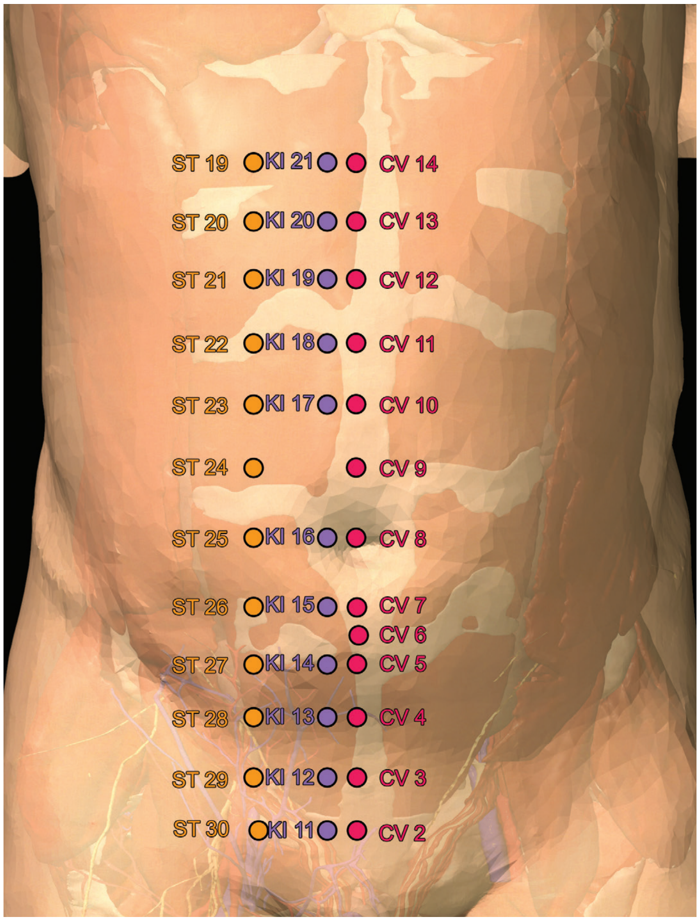

Figure 3-53. The ST, KI, and CV lines form a grid-like array on the abdomen. Note that each row of points corresponds to the same spinal nerve branch or dermatome.

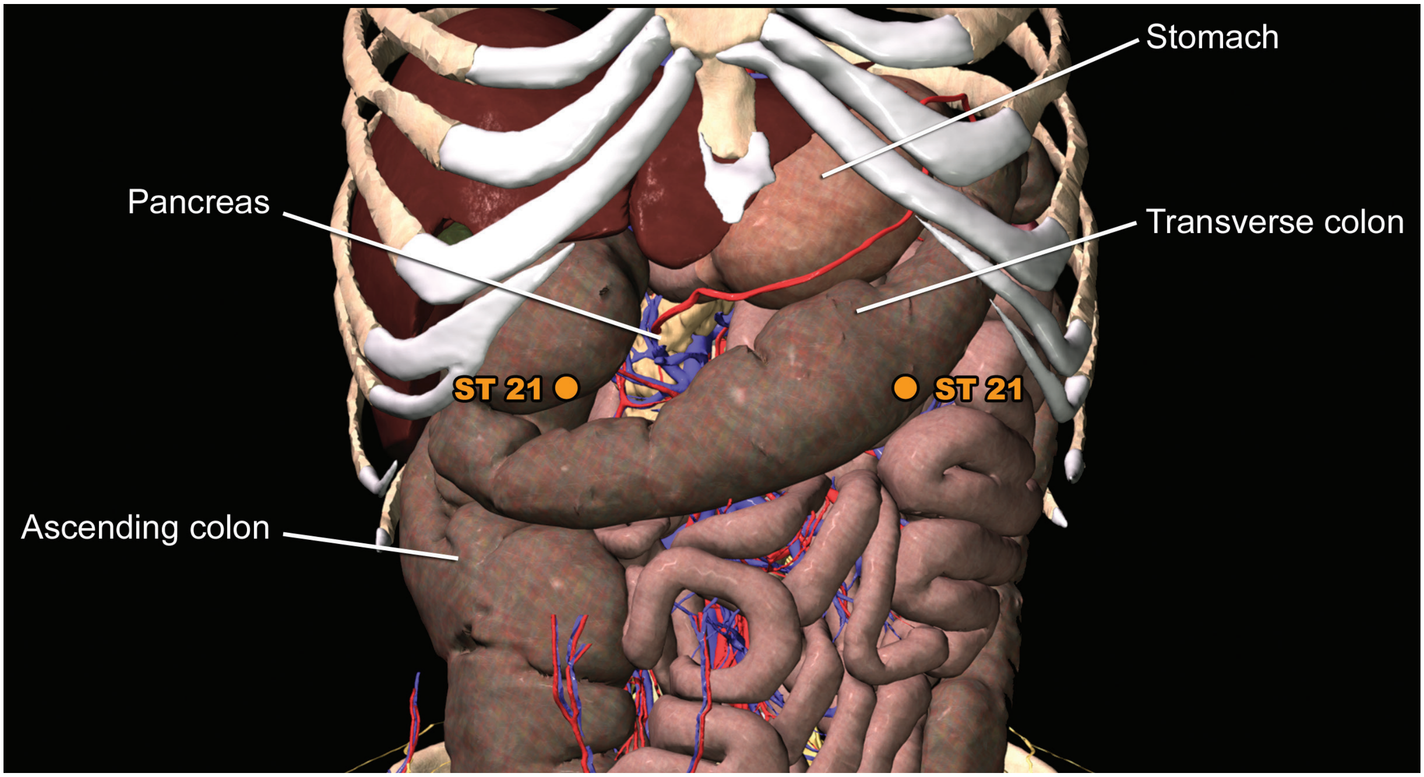

Figure 3-54. Most of the images in this text illustrate the points only on one side of the body, although all of the channels except for Governor Vessel (GV) and Conception Vessel (CV) are bilateral. The left sided points were usually omitted in order to allow unobstructed visualization of the anatomy. However, this image shows ST 21 bilaterally to illustrate the different organs the right and left points overlie. Chinese medicine refers to ST 21 as the "Gateway between the Upper and Lower Heaters". This organ layer reveals how ST 21 demarcates the transition between the upper and lower abdominal organs. Furthermore, the descriptive term "Beam Gate" harkens back to a condition called "deep-lying beam" in the *Classic of Difficulties* (Nan Jing) [See Ellis et al, *Grasping the Wind*, pp. 74-75]. One can imagine how a full and impacted, or possibly tumorous transverse colon may have given the impression that a "deep-lying beam" was occupying the cranial abdomen from ST 21 to ST 21, as shown in this image. Ellis et al describe this malady "as a condition in which a palpable mass the size of an arm located in the upper abdomen causes irritability and insomnia".

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

Indications and Potential Point Combinations

- **Gastrointestinal problems:** lack of appetite, indigestion, diarrhea, gastric ulcer, gastritis, vomiting: ST 21, CV 12, and ST 36. Add PC 6 for nausea/vomiting or gastritis; SP 6 for diarrhea.
- **Cranial abdominal wall discomfort:** ST 21, KI 19, CV 12, BL 21, BL 50 and local trigger points; modify according to level(s) of involvement.

Figure 3-55. Note how a needle entering ST 21, KI 19, and CV 12 would impact different portions of the rectus abdominis and surrounding connective tissue. This becomes clinically important if the patient is experiencing abdominal wall discomfort from nerves undergoing compression or irritation from myofascial restriction. According to Applegate, "The thoracoabdominal nerves, which terminate as the cutaneous nerves, are anchored at six points: 1) the spinal cord; 2) the point at which the posterior branch originates; 3) the point at which the lateral branch originates; 4) the point at which the anterior branch makes a nearly 90° turn to enter the rectus channel; 5) the point from which accessory branches are given off in the rectus channel; and 6) skin." The right angled turn made by the ventral branch takes place at the KI channel; the ventral rami branch at the KI points, sending one branch to the midline at the CV point and one toward the ST point. Thus, although the three points share a dermatome, each point has a particular relationship with unique anatomical sites along the ramus that may or may not be experiencing pressure from myofascial dysfunction on the abdominal wall.

ST 22

Guan Men "Pass Gate" or "Closed Gate"

On the abdomen, 3 cun above the umbilicus, approximately 2 cun lateral to the anterior midline, in the rectus abdominis muscle, midway between its lateral border (linea semilunaris) and the linea alba. Level with CV 11 and KI 18.

Note: Deep needling may result in organ puncture.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation. Like the muscles in the cheek on the face, the rectus abdominis does not lie on any supportive skeletal structure. This lack of bony attachment makes the rectus abdominis vulnerable to sudden strains, as occur with coughing or sitting upright from a supine position.[1]
- **External oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Superior epigastric artery and vein:** Arises from the internal thoracic artery and vein to supply and drain the upper portion of the rectus abdominis muscle. Anastomose with the inferior epigastric artery and vein.
- **Inferior epigastric artery and vein:** Terminal medial branch of

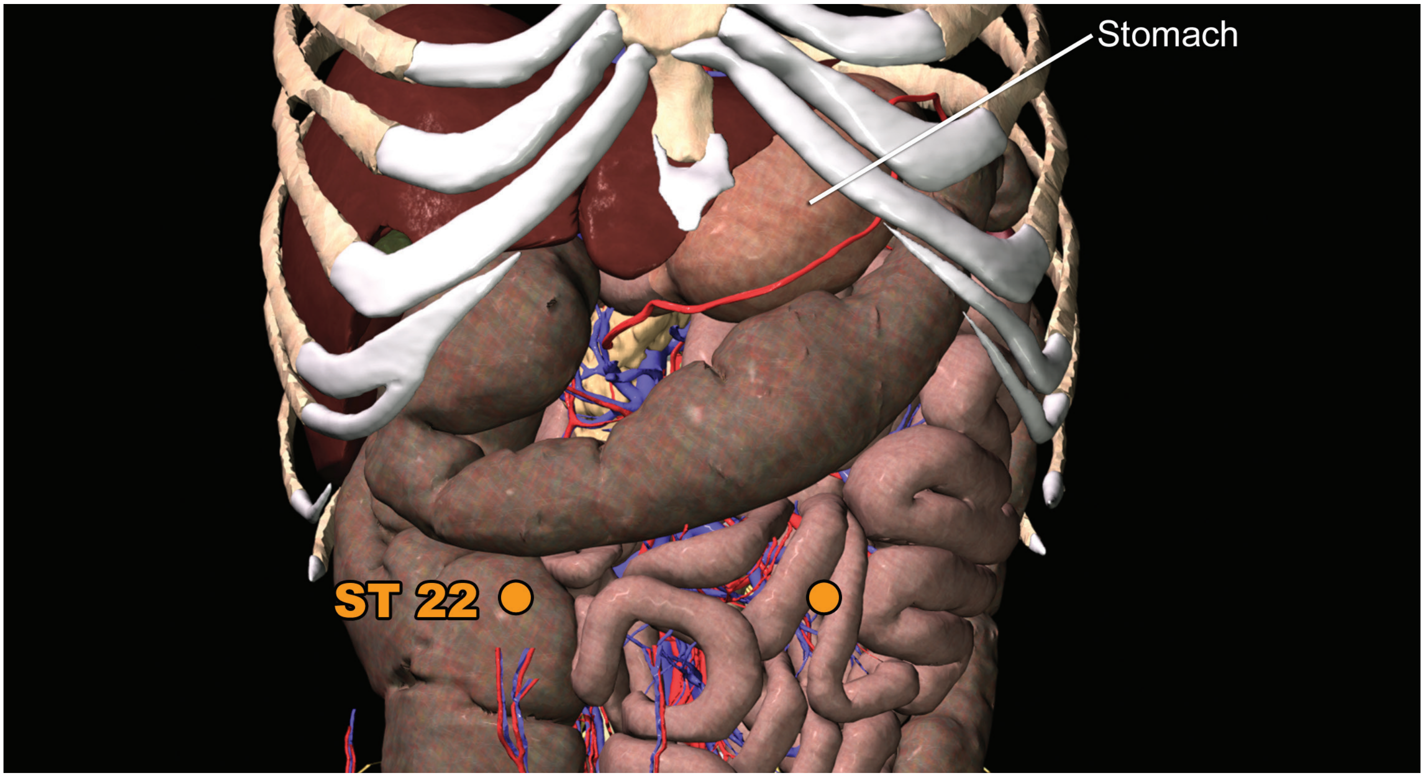

Figure 3-56. The name "Pass Gate" for ST 22 may apply to the junctures between the transverse colon and the ascending and descending colon on the right and left sides, respectively. Here, the right ST 22 resides near the right, or hepatic flexure where the colon makes a sharp turn. In cases of constipation or impaired motility, the alternative name of "Closed Gate" may seem more reasonable.

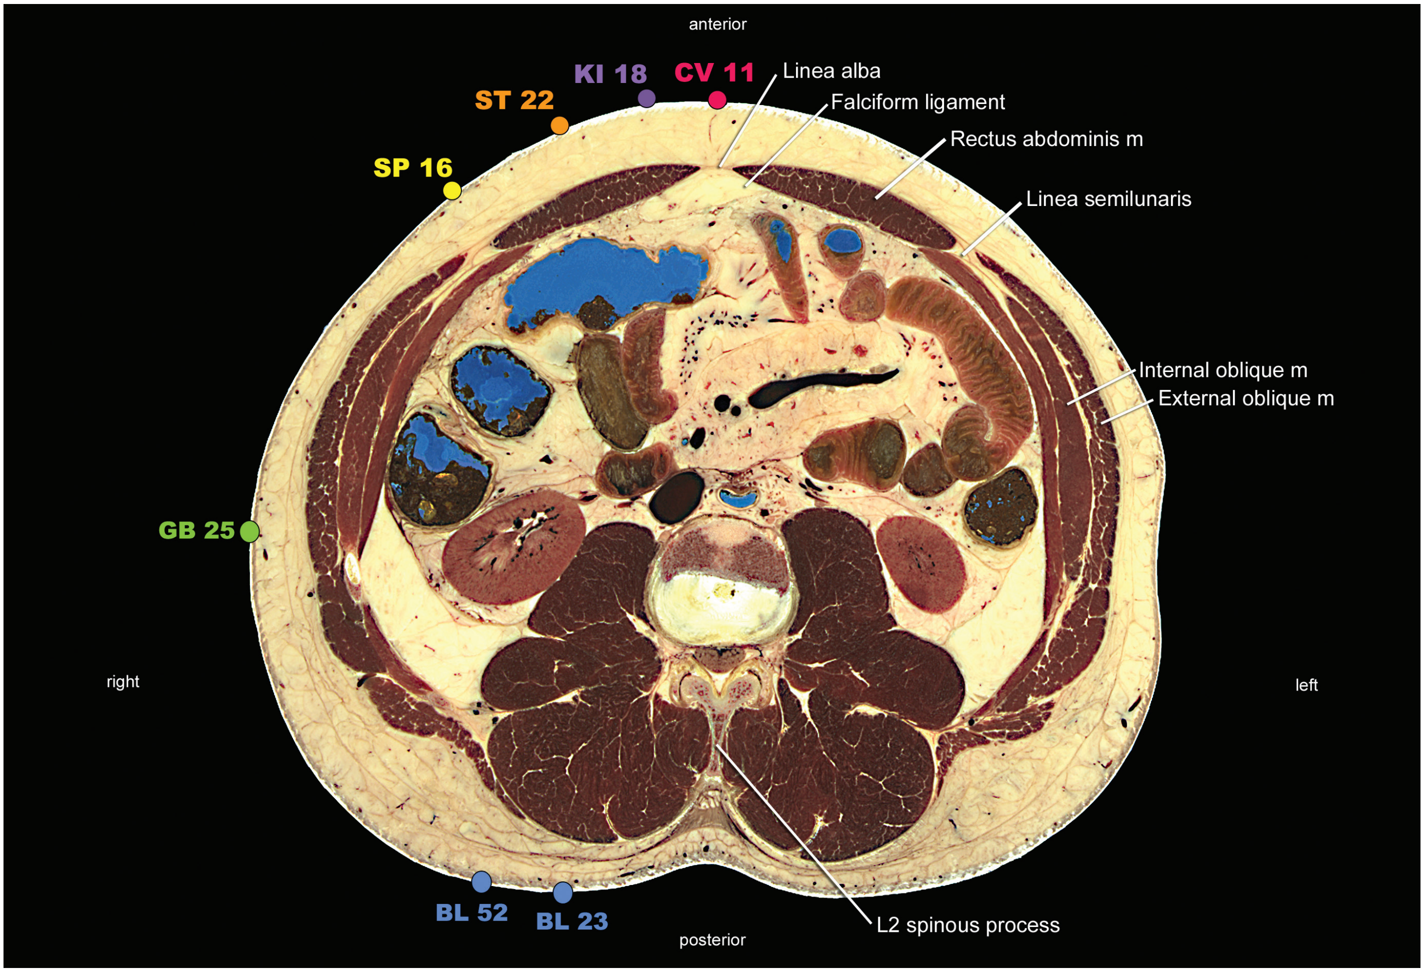

Figure 3-57. The L2/L3 level of the trunk demonstrates the co-existence of digestive and renal structures and points. For example, ST 22 ("Pass Gate") sits adjacent to KI 18, "Stone Pass".

the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath. Rupture of the inferior epigastric artery following coughing episodes can cause acute abdominal pain and rectus sheath hematoma.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[3] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[4]

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

Indications and Potential Point Combinations

- **Gastrointestinal indications: abdominal distension, dyspepsia, diarrhea, poor appetite:** ST 22, ST 36, PC 6, CV 12.
- **Cranial abdominal wall discomfort:** ST 22, KI 18, CV 11, BL 22, BL 51 and local trigger points; modify according to level(s) of involvement.

Evidence-Based Applications

- **Acupuncture at CV 4, BL 23, BL 25, and ST 25 offers an alternative to pharmacologic sedation and analgesics in patients receiving extracorporeal shockwave lithotripsy who are unable to tolerate medication.[2]**
- **Acupuncture at LI 4, LI 11, LR 3, SP 6, ST 25, ST 27, and ST 36 improved well-being and reduced bloating in patients with irritable bowel syndrome.[3]**
- **Daily electroacupuncture in obese women at LI 4, LI 11, ST 25, ST 36, ST 44, and LR 3 decreased total serum cholesterol, low-density lipoprotein (LDL), and triglyceride levels compared to control groups, possibly by increasing serum beta endorphin.[4]**
- **Moxibustion (using Artemisia vulgaris) at CV 12, ST 25, and ST 36 was effective in preventing acute gastric lesions induced by indomethacin in rats.[5]**
- **Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific ulcerative colitis in a case series.[6]**
- **A case series reported that acupuncture and moxibustion at ST 25 and CV 4 effectively improved symptoms in patients with chronic colitis.**
- **Stimulation of afferent nerves of the abdomen and lower chest by manual twisting of acupuncture needles nearly always inhibits gastric motility, in comparison to stimulation of afferent fibers in the limbs, which tend to increase motility.[7] Acupuncture-like stimulation of points in these caudal truncal segments activates lower thoracic spinal nerves, which produces an increase in gastric sympathetic efferent nerve activity and a simultaneous inhibition of gastric motility.**

ST 26

Wai Ling "Outer Mound"

On the abdomen, 1 cun below the umbilicus, approximately 2 cun lateral to the anterior midline, in the rectus abdominis muscle. Level with CV 7.

Note: Deep needling may result in organ puncture.

Muscles

- **Rectus abdominis muscle:** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, leading to exhalation. Like the muscles in the cheek on the face, the rectus abdominis does not lie on any supportive skeletal structure. This lack of bony attachment makes the rectus abdominis vulnerable to sudden strains, as occur with coughing or sitting upright from a supine position.[1]
- **External oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis muscle:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Entrapment of spinal nerves' ventral rami has been identified as the most common cause of abdominal wall pain.[2] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Vessels

- **Inferior epigastric artery and vein:** Terminal medial branch of the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath.

Rupture of the inferior epigastric artery following coughing episodes can cause acute abdominal pain and rectus sheath hematoma.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[3] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[4]

Should the major conduits of blood, i.e., the aorta and venae cavae, become obstructed or stenotic as in severe aortoiliac occlusive disease, these superficial vessels on the abdominal wall provide collateral pathways for circulation. These communicating vessels course within loose areolar tissue deep to the rectus abdominis muscle. They constitute a lengthy anastomosis between the femoral vessels of the pelvis and the internal thoracic (internal mammary) vessels of the chest.

Acupuncture should be avoided in an area of abdominal wall expansion if rectus hematoma is suspected. However, after appropriate measures have controlled the bleeding and hypotensive consequences, neuromodulation may be attempted with non-invasive means to improve recovery of the area. That is, while acupuncture, laser therapy, and massage would be contraindicated in the acute phase where bleeding is active, they may be appropriate after the risk of hemorrhage has passed and if employed cautiously and judiciously to avoid and prevent further vessels damage.

ST 29

Gui Lai "Return"

On the lower abdomen, 1 cun above the pubic symphysis, approximately 2 cun lateral to the anterior midline, in the lateral border of the rectus abdominis muscle. Level with CV 3.

Spermatic Cord

Contents include

- Testicular artery
- Deferential artery
- Cremasteric artery
- Nerve to the cremaster (genital branch of the genitofemoral nerve)
- Testicular nerves (sympathetic nerves)
- Vas deferens (ductus deferens)
- Pampiniform plexus
- Lymphatic vessels
- Tunica vaginalis
- External spermatic fascia (an extension of the fascia that overlies the aponeurosis of the external oblique muscle)
- Cremasteric muscle and fascia (a continuation of the internal oblique muscle and fascia)
- Internal spermatic fascia (continuous with the transversalis fascia)

Clinical Relevance: Although one's acupuncture needle should not reach the spermatic cord, ST 29 overlies this important structure. As such, point activation with electroacupuncture, manual therapy, needle manipulation, or laser therapy may influence the function and blood supply of the cord's contents. That is, the vessels may dilate, the nerves may modulate, and myofascial elements relax. The result would likely lead to improved testicular function and reproductive capacity. See Figures 3-71 and 3-72 for two view of the anatomical relationships between ST 29 and the spermatic cord.

Muscles

- **Rectus abdominis muscle (lateral margin):** Flexes the trunk via flexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, resulting in exhalation.
- **External oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique muscle:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Aponeurosis of the transversus abdominis muscle:** The transversus abdominis muscle compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the

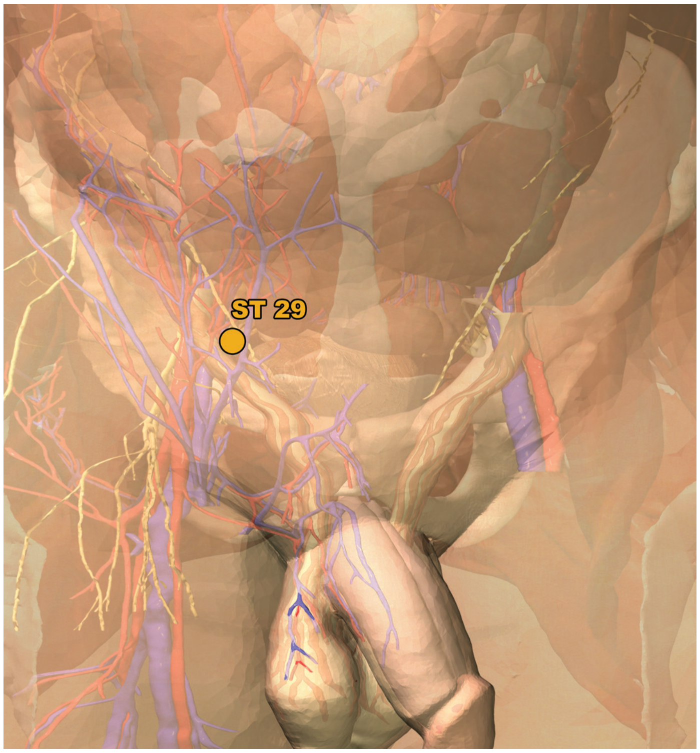

Figure 3-71. ST 29 resides close to the inguinal canal and spermatic cord,as seen here through semi-transparent skin. This helps to explain the ability of EA (10 Hz) to improve testicular artery blood flow when delivered to ST 29 but not ST 25, which does not share the same neurovascular supply. Impaired testicular artery blood flow may predispose men to reproductive organ dysfunction. Conditions impacted by reduced microcirculation in this artery include varicocele, reduced spermatogenesis, and infertility resulting from a prematurely aged testis. In another clinical scenario, the condition known as "acute scrotum", a syndrome afflicting neonates, children, and adolescents, involves torsion of the spermatic cord. Acute scrotum constitutes a surgical emergency; its after effects can compromise future fertility because prolonged periods of torsion damage tissue through generation of reactive oxygen species after reperfusion of the ischemic region. Given the aforementioned findings demonstrating improved testicular arterial blood flow following EA at ST 29, 10 Hz EA may maintain testicular function, at least in the contralateral testis while awaiting detorsion surgery for the ipsilateral organ. The singular vessel "Dai Mai", associated with L1 and the sympathetic/somatic activities of the iliohypogastric and ilioinguinal nerves, drops down in the front in the ST 29 region, draped like a belt around the caudal torso. As described elsewhere in the text, the neuroanatomic underpinnings of the Dai Mai "Vessel" relate not only to the subcostal artery and vein, but also to the autonomic activities overseen by the L! spinal cord segment. Specifically, this includes hemodynamics (specifically, vasoconstriction) to the buttocks, low back, and genitalia, as well as reproductive function and homeostasis.

periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3):**[4] The iliohypogastric nerve is the first nerve of the lumbar plexus.[5] The lumbar plexus if formed from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or caudal to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.

A mixed sensory and motor nerve, the iliohypogastric supplies the skin of the hypogastric region, the iliac crest area, the internal oblique muscle and the transversus abdominis.

The iliohypogastric nerve communicates with the subcostal and ilioinguinal nerves. The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[6] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

- **Ilioinguinal nerve (L1):** Travels through the inguinal canal. Innervates the skin of the upper scrotum or labium majus, root of the penis, mons pubis, and nearby medial thigh. Also supplies the internal oblique and transversus abdominis muscles. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with the genitofemoral nerve (L1,L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[7]
- **Spermatic ganglion:** Connected to the caudal (inferior) mesenteric plexus, likely sympathetic, supplying, at least in part, the testicular artery.[8]

Clinical Relevance: Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[9] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Furthermore, abdominal surgery can injure nerves traveling through one or more planes of the abdominal wall. Paresis of the rectus abdominis muscle may result, and bulging of the abdominal wall may ensue.[10] Paresis of the abdominal wall may cause large swelling and mechanical complaints. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation, including treatment at ST 29. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also be addressed with neuromodulation,

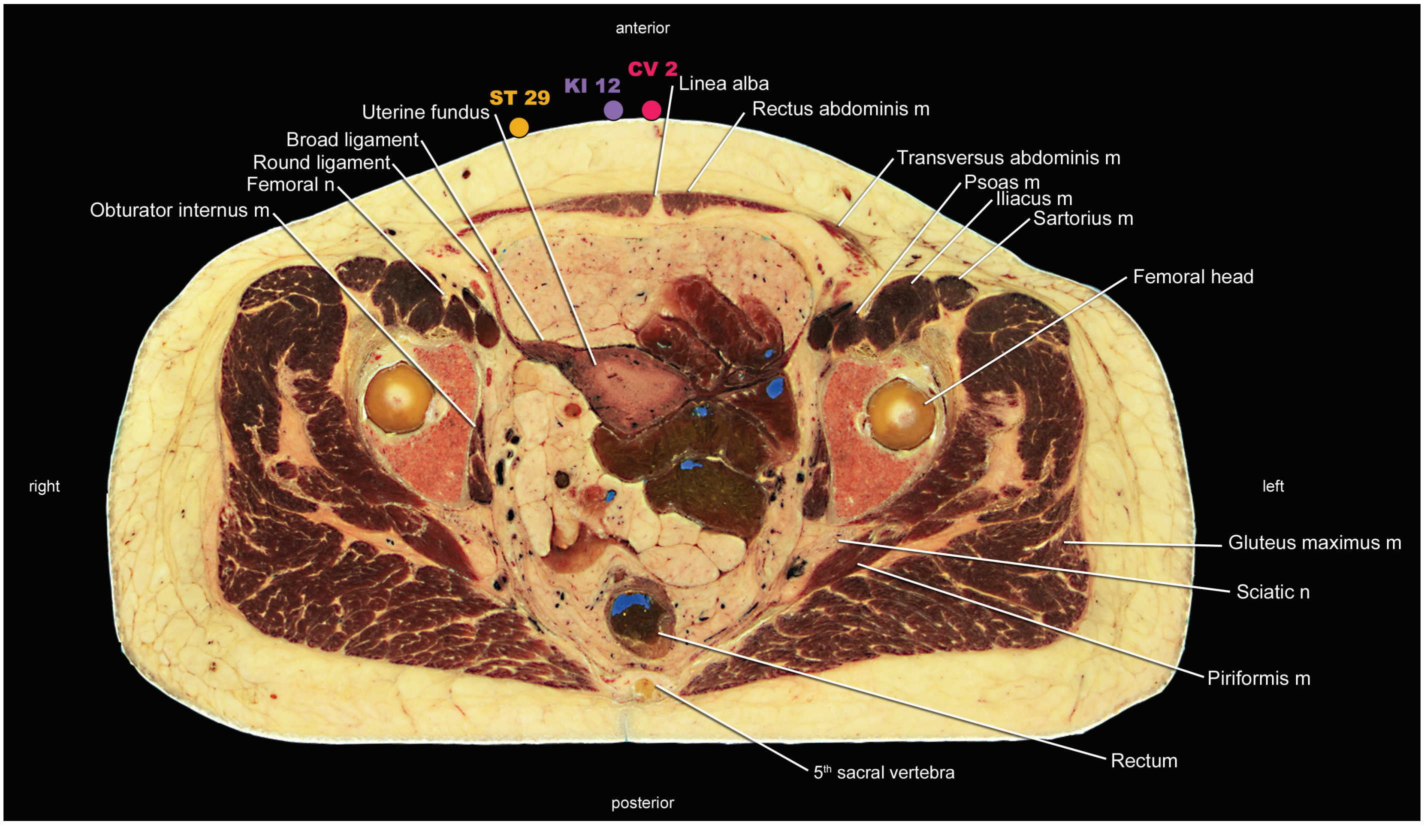

Figure 3-73. The descriptive name for this point, "Return" connotes the application of this point for uterine prolapse or restoration of menstruation in cases of amenorrhea. Note: this cross section depicts the female anatomy from the Visible Female project.

in addition to adjunctive abdominal support and multimodal analgesia.

The variability in spinal nerve origin for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy. Conversely, issues related to pain or dysfunction of somatic or visceral tissues served by the T12-L2 spinal segments may benefit from neuromodulation applied to ST 29, KI 12, and CV 3 (see Figure 3-72 for their placement on the caudal abdomen).

Vessels

- **Inferior epigastric artery and vein:** Terminal medial branch of the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath.

Rupture of the inferior epigastric artery following coughing episodes can cause acute abdominal pain and rectus sheath hematoma.

Clinical Relevance: Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[11] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.[12]

Indications and Potential Point Combinations

- **Amenorrhea, irregular menses, endometritis, infertility, uterine prolapse:** ST 29, ST 30, CV 4, SP 4, PC 6, BL 23
- **Orchitis:** ST 29, CV 2, LR 5.
- **Male infertility:** ST 29, BL 22, CV 4, SP 6.
- **Hernia:** ST 29, ST 30, BL 22, BL 23, CV 2.
- **Penile and scrotal problems:** pain, inflammation, retraction: ST 29, BL 22, CV 2, SP 6.

Evidence-Based Applications

- Electroacupuncture (at ST 29 and TH 5 to LI 4) with manual acupuncture at GV 20 and ST 36 serve as an **effective analgesic during oocyte aspiration;** these analgesic effects equal those of conventional analgesics.[1] Neuropeptide Y (NPY) concentrations in follicular fluid were higher in the electroacupuncture group than in the medication group; NPY may be important for human ovarian steroidogenesis.[2]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in improvement in **sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[3]
- Electroacupuncture (EA) at 10 Hz, applied to ST 29, increased **testicular blood flow** whereas dry needling and 2 Hz stimulation did not. In contrast, EA at 10Hz applied to ST 25 did not change testicular blood flow significantly. This finding emphasizes the need to consider neurovascular supply to a dysfunctional organ and the neuromodulatory pathways to affect that supply in order to achieve clinically significant outcomes.[13]

ST 30

Qi Chong "Surging Qi"

Level with the pubic symphysis and CV2, 2 cun lateral to the midline, just superior to the inguinal ligament, on the medial side of the femoral artery.

Spermatic Cord

Contents include

- Testicular artery
- Deferential artery
- Cremasteric artery
- Nerve to the cremaster (genital branch of the genitofemoral nerve)
- Testicular nerves (sympathetic nerves)
- Vas deferens (ductus deferens)
- Pampiniform plexus
- Lymphatic vessels
- Tunica vaginalis
- External spermatic fascia (an extension of the fascia that overlies the aponeurosis of the external oblique muscle)
- Cremasteric muscle and fascia (a continuation of the internal oblique muscle and fascia)
- Internal spermatic fascia (continuous with the transversalis fascia)

Clinical Relevance: Although one's acupuncture needle should not reach the spermatic cord, ST 29 overlies this important structure. As such, point activation with electroacupuncture, manual therapy, needle manipulation, or laser therapy may influence the function and blood supply of the cord's contents. That is, the vessels may dilate, the nerves may modulate, and myofascial elements relax. The result would likely lead to improved testicular function and reproductive capacity. See Figures 3-75 and 3-76 for two views of the anatomical relationships between ST 30 and the spermatic cord.

Connective Tissues

- **Round ligament of the uterus (ligamentum teres uteri) in females:** Connects the uterus to each labium majus. Each ligament exits the pelvis through the deep inguinal ring, passing through the inguinal canal to reach the labia majora. There, the ligaments' fibers spread and mix with tissue comprising the mons pubis.
- **Superficial (external) inguinal ring, or exit from the inguinal canal:** This aperture between the diagonal fibers of the external oblique aponeurosis transmits either the spermatic cord in males or the round ligament of the uterus in females.

Clinical Relevance: Round ligament varicosities may develop during pregnancy, leading to groin swelling. The varicosities arise from veins that drain the inguinal canal and round ligament. Because flow in these veins increases during pregnancy but venous wall tone decreases, these varicosities become more common in pregnant women. Due to its clinical resemblance with an inguinal hernia, misdiagnosis is common and unnecessary surgery may result.[5] "Round ligament syndrome" refers to a painful condition in the groin of pregnant women. Uterine growth in pregnancy stretches the ligaments, producing pain.[6] Releasing soft tissue strain with acupuncture and manual therapy at and around ST 30 may ease the pull on these pelvic ligaments and thereby alleviate pain.

Muscles

- **Rectus abdominis muscle (lateral margin):** Flexes the trunk viaflexing the lumbar vertebrae; compresses abdominal organs. Is a diaphragm antagonist, resulting in exhalation.
- **Aponeurosis of the internal and external oblique muscles:** The muscles flex and rotate the trunk, as well as support and compress the abdominal organs. The inferior margin of the external oblique aponeurosis thickens and folds over onto itself to create the inguinal ligament, which attaches to the anterior superior iliac spine and pubic tubercle.
- **Aponeurosis of the transversus abdominis muscle:** The transversus abdominis muscle compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress.

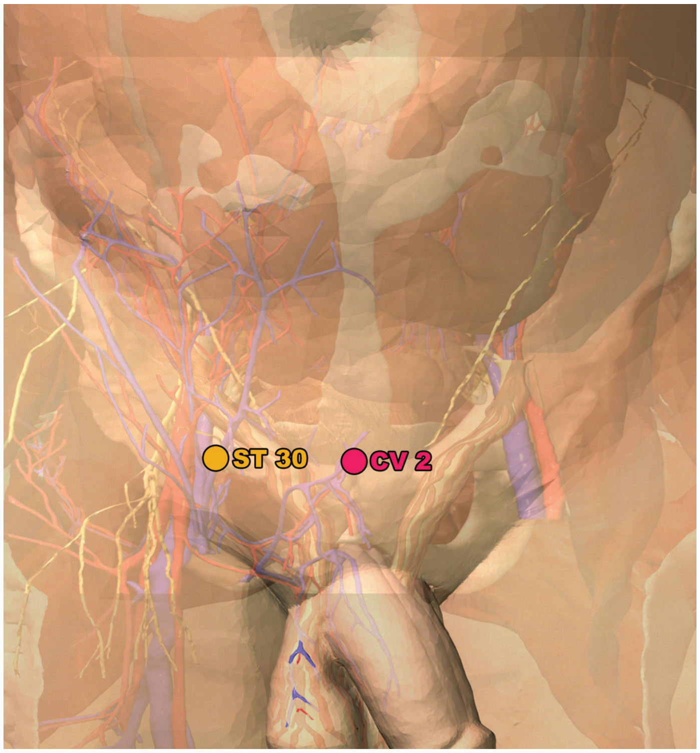

Figure 3-74. ST 30, "Qi Thoroughfare" or "Surging Qi", connotes the prominent neurovasculature ferrying blood and neural traffic, as seen through the transparent skin in this image.

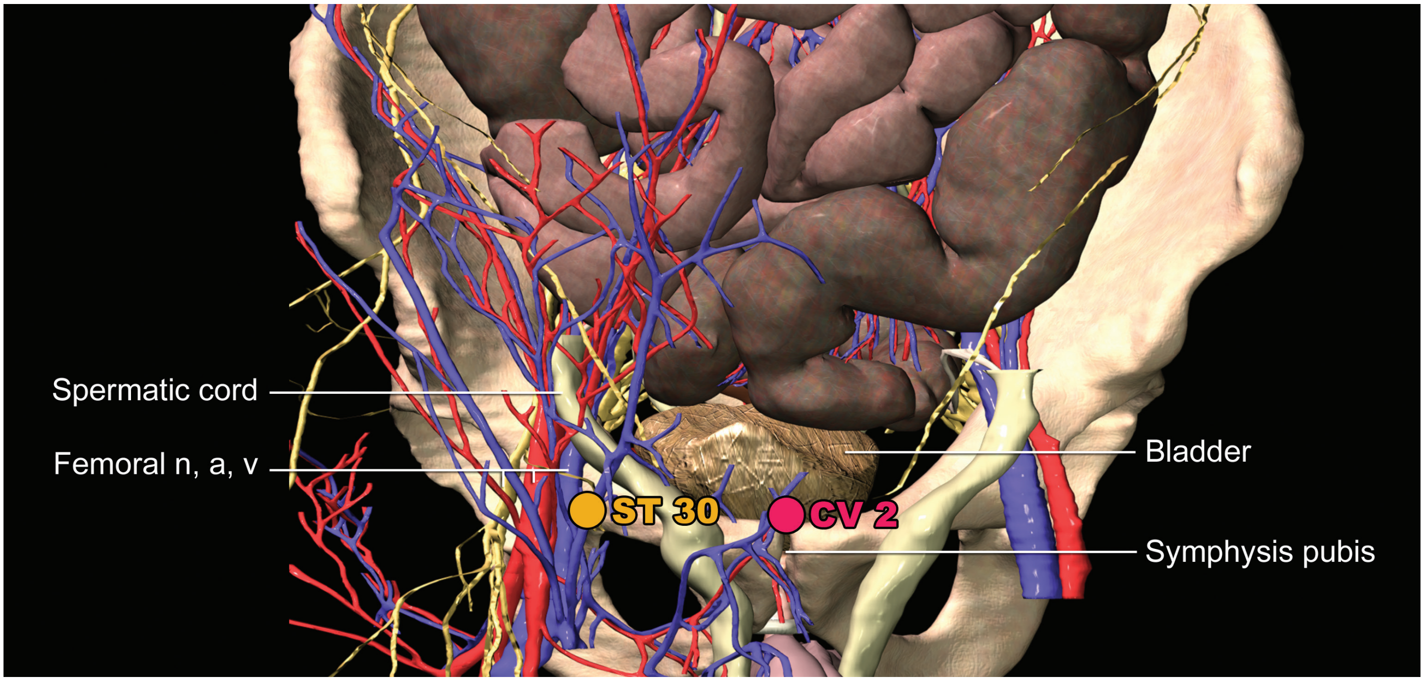

Figure 3-75. This neurovascular layer provides a clearer view of the femoral vein, artery, and nerve that reside close to ST 30. Note also the proximity of the spermatic cord.

Nerves

- **Genitofemoral nerve (L1, L2):** Provides afferent and efferent limbs of the cremasteric reflex. The ilioinguinal nerve (L1) helps with the afferent aspect. The genitofemoral nerve emerges on the ventral aspect of teh psoas major muscle. It divides into a femoral branch and a genital branch. The femoral branch supplies the skin over the femoral triangle. In males, the genital branch travels through the inguinal canal, accompanying the spermatic cord. It them supplies the skin of the scrotum and the cremaster muscle. In females, the genital branch of the genitofemoral nerve provides cutaneous sensation to the mons pubis and labia majora.

- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[7]):** The iliohypogastric nerve is the first nerve of the lumbar plexus.[8] The lumbar plexus if formed from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or caudal to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.

A mixed sensory and motor nerve, the iliohypogastric supplies the skin of the hypogastric region, the iliac crest area, the internal oblique muscle and the transversus abdominis.

The iliohypogastric nerve communicates with the subcostal and ilioinguinal nerves.The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[9] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

- **Ilioinguinal nerve (L1):** Travels through the inguinal canal. Innervates the skin of the upper scrotum or labium majus, root of the penis, mons pubis, and nearby medial thigh. Also supplies the internal oblique and transversus abdominis muscles. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with the genitofemoral nerve (L1, L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[10]

- **Spermatic ganglion:** Connected to the caudal (inferior) mesenteric plexus, likely sympathetic, supplying, at least in part, the testicular artery.[11]

Clinical Relevance: Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[12] The nerves become entrapped where they move through a fibrous or osseofibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can contribute to nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

Abdominal surgery can injure nerves traveling through one or more planes of the abdominal wall. Paresis of the rectus abdominis muscle may result, and bulging of the abdominal wall may ensue.[13] Paresis of the abdominal wall may cause large swelling and mechanical complaints. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation, including treatment at ST 29. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also

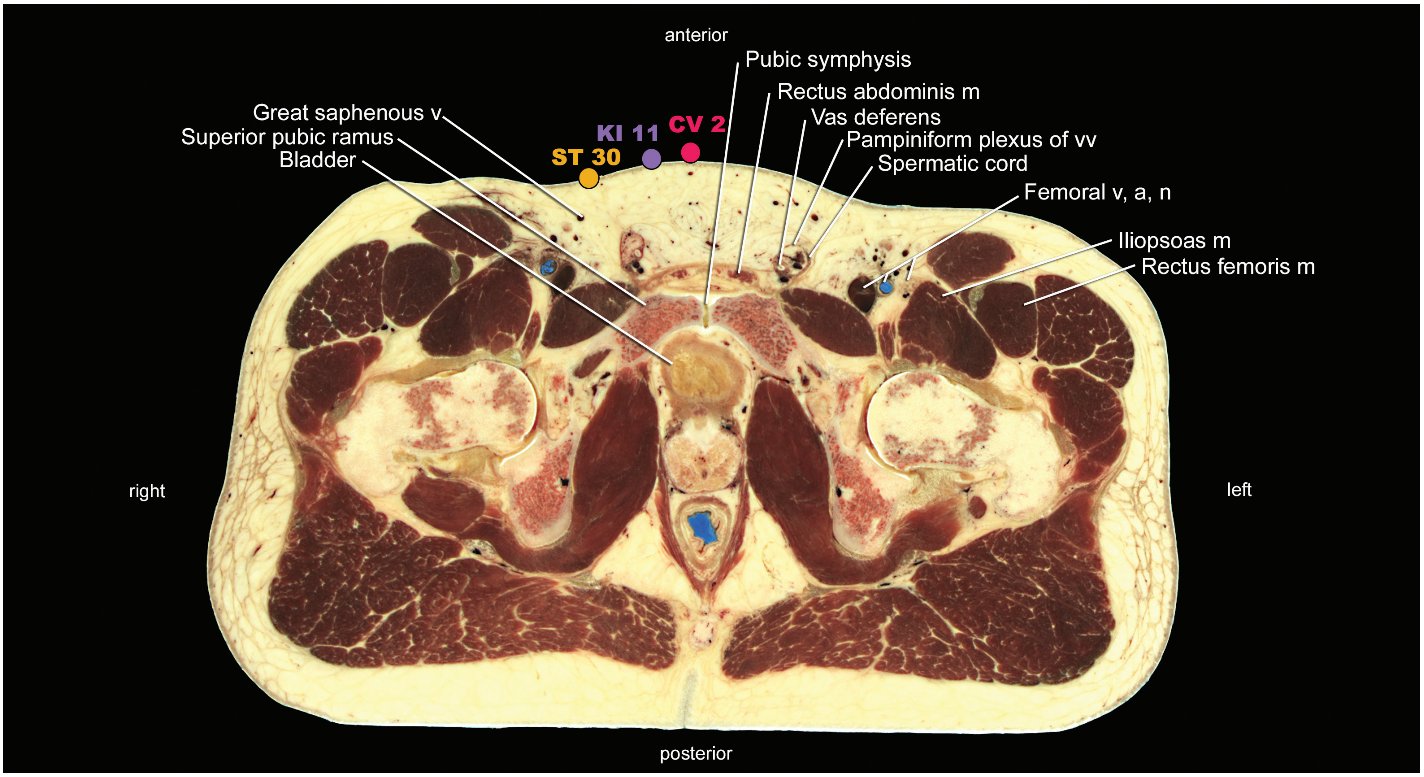

Figure 3-76. ST 30 in the male sits in a nook between the femoral vessels and the spermatic cord.

be addressed with neuromodulation, in addition to adjunctive abdominal support and multimodal analgesia.

The variability in spinal nerve origin for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy. Conversely, issues related to pain or dysfunction of somatic or visceral tissues served by the T12-L2 spinal segments may benefit from neuromodulation applied to ST 29, KI 12, and CV 3 (see Figure 3-72 for their placement on the caudal abdomen).

Neuromodulation to the territories supplied by the genitofemoral and pudendal nerves may offer analgesia for various types of pelvic pain. For example, transcutaneous electrical nerve stimulation (TENS) provided low cost, easily applied analgesia for primiparous puerpere post-episiotomy.[14]

Genitofemoral neuralgia, post-operative pain, and dyspareunia may occur following transobturator midurethal sling placement for stress urinary incontinence.[15] Although midurethral slings are mainstay treatments for stress urinary incontinence, postoperative pain may occur and require neuromodulation, trigger point injections, and other approaches for multimodal analgesia. Acupuncture applied to genitofemoral nerve territories may aid in the resolution of pain resulting from this condition.

Vessels

- **Inferior epigastric artery and vein:** Terminal medial branch of the external iliac artery; distributes blood to the rectus abdominis muscle and the medial part of the anterolateral abdominal wall. The inferior epigastric vessels send branches to the rectus abdominis, especially evident at the tendinous inscriptions. The vessels course along the retroperitoneal space until they enter the rectal sheath.

Lymphatic Tissue

- Superficial and deep lymphatic pathways course from the lateral heel to the inguinal lymph nodes.[16]

Indications and Potential Point Combinations

- **Genitourinary and reproductive problems:** ST 30, ST 36, SP 6, CV 3, CV 4, BL 23, BL 25, BL 28.

Evidence-Based Applications

- Acupuncture at ST 30 may impact reproductive function through its effects on afferent sensory signal transmission via the **ilioinguinal nerve**, which serves the roots of the penis and the scrotum.[1]
- A case series reported that massage at ST 30 effectively resolved **hydrocele**.[2]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia (OAT syndrome)**.[3]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[4]

ST 31

Bi Guan "Thigh Joint"

On the anterior thigh, directly inferior to the anterior superior iliac spine (ASIS), in a depression lateral to the sartorius muscle when the thigh is flexed. Approximately level with the inferior margin of the pubic symphysis.

Muscles

- **Rectus femoris muscle:** Extends the leg at the knee, and steadies the hip joint. Helps the iliopsoas muscle flex the thigh.
- **Sartorius muscle:** Acts across two joints, serving to flex the hip and help flex the knee. The sartorius muscle laterally rotates the thigh and weakly abducts it. Both sartorius muscles, acting together, bring the lower extremities into the cross-legged position.
- **Tensor fasciae latae muscle:** Inserts onto the iliotibial tract after joining fibers from the gluteus maximus muscle. Acts as a flexor of the thigh, usually in conjunction with the iliopsoas muscle. Helps medially rotate the thigh in conjunction with the gluteus medius and gluteus minimus muscles. Contracts during hip abduction, most likely acting as a synergist or fixator muscle.

Clinical Relevance: ST 31 coincides coincides with a trigger point in the rectus femoris m. Myofascial dysfunction at this site can radiate pain to the knee, following the muscle belly to its attachments at the patella.

Nerves

- **Femoral nerve (L2-L4):** Innervates the quadriceps femoris muscle group, which extends the leg at the knee. Also supplies the iliacus, pectineus, and sartorius muscles. The femoral nerve provides articular branches to the hip joint and the knee joint, and provides a number of cutaneous branches that serve the anteromedial thigh region. The femoral nerve terminates as the saphenous nerve, a cutaneous branch. The saphenous nerve supplies the skin and fascia of the anteromedial portions of the knee, leg, and foot.
- **Superior gluteal nerve (L4, L5):** Innervates the tensor fasciae latae muscle.
- **Lateral femoral cutaneous nerve (L2, L3):** Provides sensation to the skin on the lateral and anterior thigh. The nerve travels beneath the psoas major muscle and enters the thigh region after it passes beneath the inguinal ligament in the groin. At this point, it pierces the fascia lata to divide into anterior and posterior branches.[3] Anatomical variations may cause certain nerve branches to be more susceptible to impingement in some individuals than in others.

Clinical Relevance: Entrapment mononeuropathy of the lateral femoral cutaneous nerve has been implicated in meralgia paresthetica, a clinical syndrome involving burning pain and/or dysesthesia in the anterolateral thigh.[1]

Contributing factors to meralgia paresthetica include 1) Repetitive or continuous contraction or pathological shortening of the iliopsoas and sartorius muscles, 2) Pelvic tilt and limb length discrepancy that place heightened tension on the inguinal ligament, and 3) Anatomic variations that make the lateral femoral cutaneous nerve more vulnerable to compression.[4]

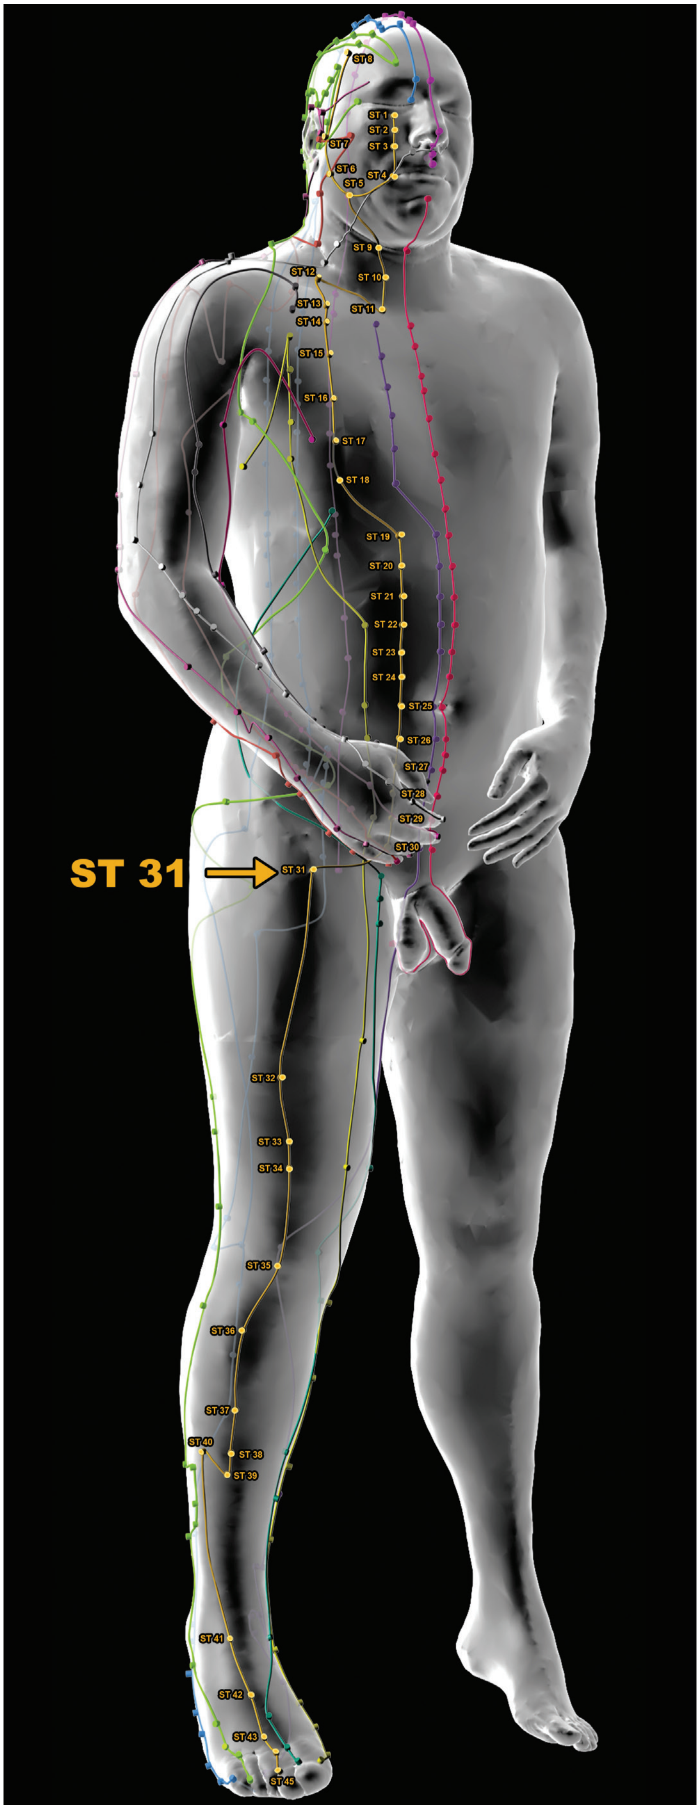

Figure 3-77. ST 31, "Thigh Joint", as shown here, stands level with the inferior border of the pubic symphysis, on the lateral edge of the sartorius muscle and directly inferior to the anterior superior iliac spine. Its name aptly describes its location.

In addition to treating local points with acupuncture, one might consider addressing spinal cord segments that give rise to this nerve (L2-L3), inspired by the approach involving spinal cord stimulation for this condition.[2]

Vessels

- **Superior gluteal artery:** Supplies the tensor fasciae latae muscle.
- **Lateral circumflex femoral artery, ascending and transverse branches:** Supply the femoral head and lateral thigh musculature.

Clinical Relevance: Improving circulation through the lateral circumflex femoral artery aids in supplying blood to the hip joint.

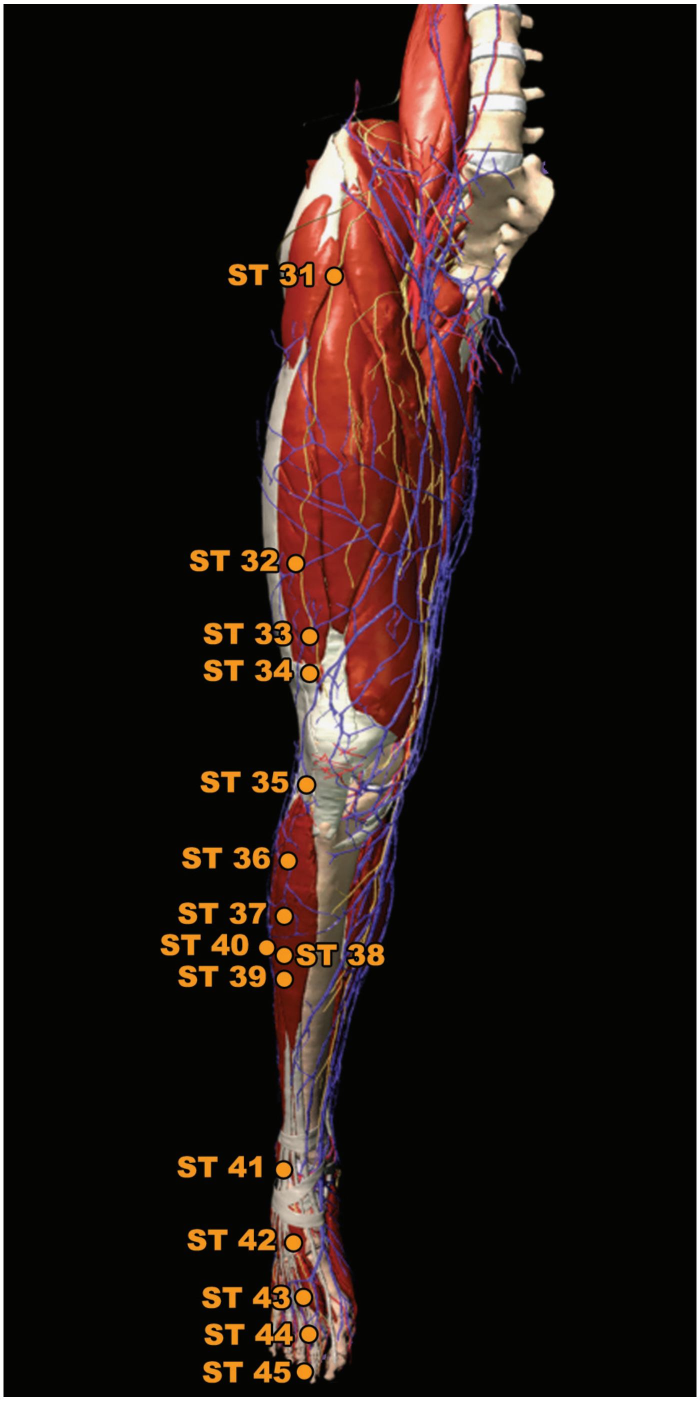

Figure 3-78. ST 31 appears here in relation to other points on the ST line of the pelvic limb.

Rupture of the superior gluteal artery can lead to gluteal compartment syndrome subsequent to hip dislocation.[5] The superior gluteal artery is the most commonly injured artery from stab wounds and other penetrating injuries to the gluteal region, so caution is advised when needling deeply in the hip area.

Indications and Potential Point Combinations

- **Muscle tension (local), thigh pain, hip pain:** ST 31, other local trigger points in muscles responsible for generating the pain pattern; check quadriceps femoris group (that Travell and Simons call the" four-faced trouble maker") and sartorius muscles.
- **Thigh pain**
- **Hip pain and reduced range of motion**
- **Pelvic limb paresis or paralysis**

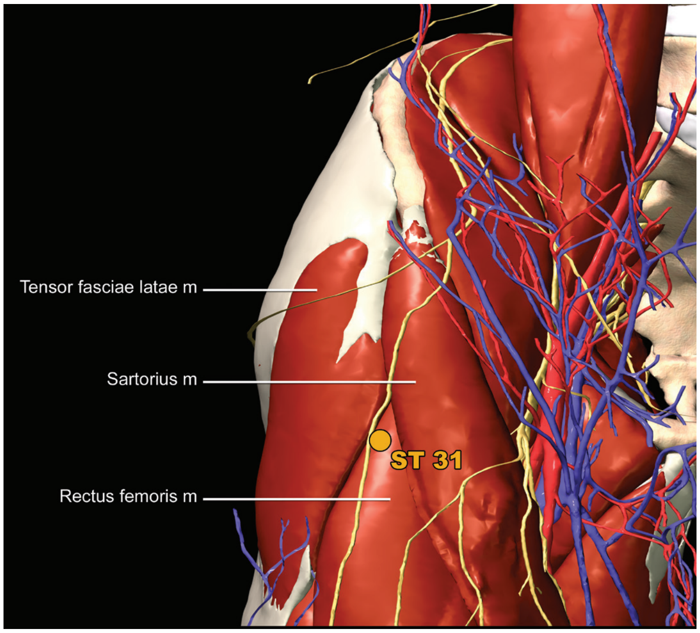

Figure 3-79. This image illustrates the relationship between the sartorius muscle and ST 31, as well as the other nearby muscles: the rectus femoris and tensor fasciae latae. Trigger points in the rectus femoris muscle at ST 31 refer strongly to the knee, earning this muscle the moniker "two joint puzzler", connoting its capacity to induce discomfort in both the hip and knee.

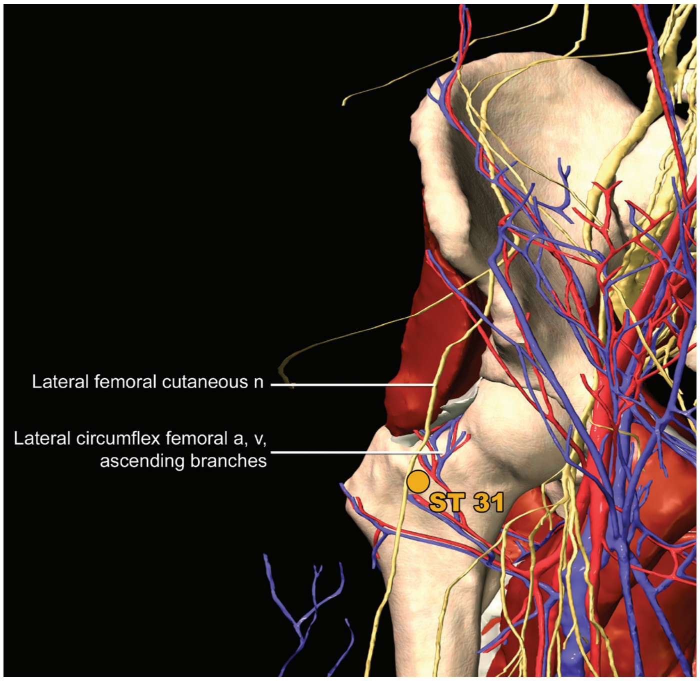

Lateral femoral cutaneous n
Lateral circumflex femoral a, v, ascending branches
ST 31

Figure 3-80. Note the proximity of ST 31 to the ascending branches of the lateral circumflex femoral artery and vein. These vessels supply and drain blood, respectively, from the femoral head region and nearby musculature. This image also reveals the proximity of ST 31 to the lateral femoral cutaneous nerve. Compressive clothing such as low-slung specific duty uniform belts, protective body armor worn by soldiers, or low-cut trousers, can injure the nerve and lead to the condition called “meralgia paresthetica”.

Figure 3-82. The “Thigh Joint” point, ST 31, associates not only with the hip joint, but also large movers acting on the thigh, including the sartorius, tensor fasciae latae, and the rectus femoris muscles.

ST 32

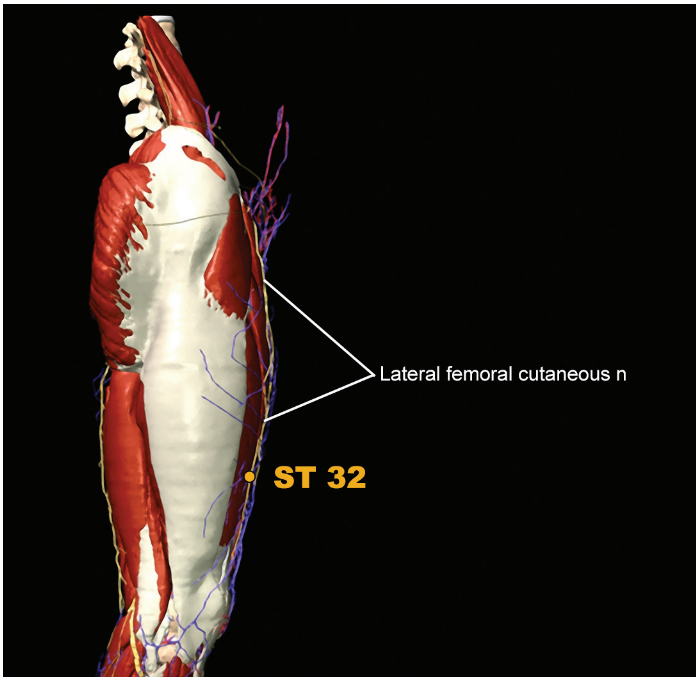
Fu Tu "Crouching Rabbit"

On the anterior thigh region, 6 cun proximal to the superolateral angle of the patella, on the line connecting the ASIS and the superolateral patella. The point can also be found by dividing into thirds the distance between the prominence of the greater trochanter and the superolateral patella. ST 32 occurs just superior to the junction of the lower and middle thirds.

Muscles

- **Rectus femoris muscle ("the two-jointed puzzler"):** Extends the leg at the knee, and steadies the hip joint. Helps the iliopsoas muscle flex the thigh.
- **Vastus intermedius muscle ("the frustrator"):** Extends the leg at the knee.
- **Vastus lateralis muscle ("stuck patella muscle"):** Extends the leg at the knee.

Clinical Relevance: A number of trigger points in the quadriceps group cause problems in the cranial thigh. In particular, trigger points in the vastus lateralis that abut the fascia lata can issue a pain sensation described as akin to a "bolt of lightning".
As noted above, each of the quadriceps components in the vicinity of ST 32 has acquired a nickname due to the diagnostic confusion to which they contribute. Muscles affected by needling ST 32 depend on the depth of needle insertion.



Lateral femoral cutaneous n
ST 32

Figure 3-83. ST 32 earned the name "Crouching Rabbit" for the bulge that appears in the living individual who is actively contracting the vastus lateralis muscle. The prominence in this bulge resembles the kyphotic spinal curvature of a rabbit crouching. While the Chinese name, "Futu", for ST 32, means "Crouching Rabbit", Futu for LI 18 means, "Support the Prominence".

Nerves

- **Anterior cutaneous branches of femoral nerve (L2-L4):** Supplies the skin on the anterior and medial parts of the thigh.
- **Lateral femoral cutaneous nerve (L2, L3):** Provides sensation to the skin on the lateral and anterior thigh.
- **Femoral nerve (L2-L4):** Innervates the quadriceps femoris muscle group, which extends the leg at the knee. Also supplies the iliacus, pectineus, and sartorius muscles. The femoral nerve provides articular branches to the hip joint and the knee joint, and provides a number of cutaneous branches that serve the anteromedial thigh region. The femoral nerve terminates as the saphenous nerve, a cutaneous branch. The saphenous nerve supplies the skin and fascia of the anteromedial portions of the knee, leg, and foot.

Clinical Relevance: Entrapment mononeuropathy of the lateral femoral cutaneous nerve has been implicated in meralgia paresthetica, a clinical syndrome involving burning pain and/or dysesthesia in the anterolateral thigh.

Contributing factors to meralgia paresthetica include 1) Repetitive or continuous contraction or pathological shortening of the iliopsoas and sartorius muscles, 2) Pelvic tilt and limb length discrepancy that place heightened tension on the inguinal ligament, and 3) Anatomic variations that make the lateral femoral cutaneous nerve more vulnerable to compression.[1]

Input from Group III- and Group IV-mediated afferent feedback through the femoral nerve influences the voluntary termination of exercise. This suggests that somatic afferent stimulation in the quadriceps muscle group may reduce peripheral fatigue and improve muscular adaptation to exercise.[2]

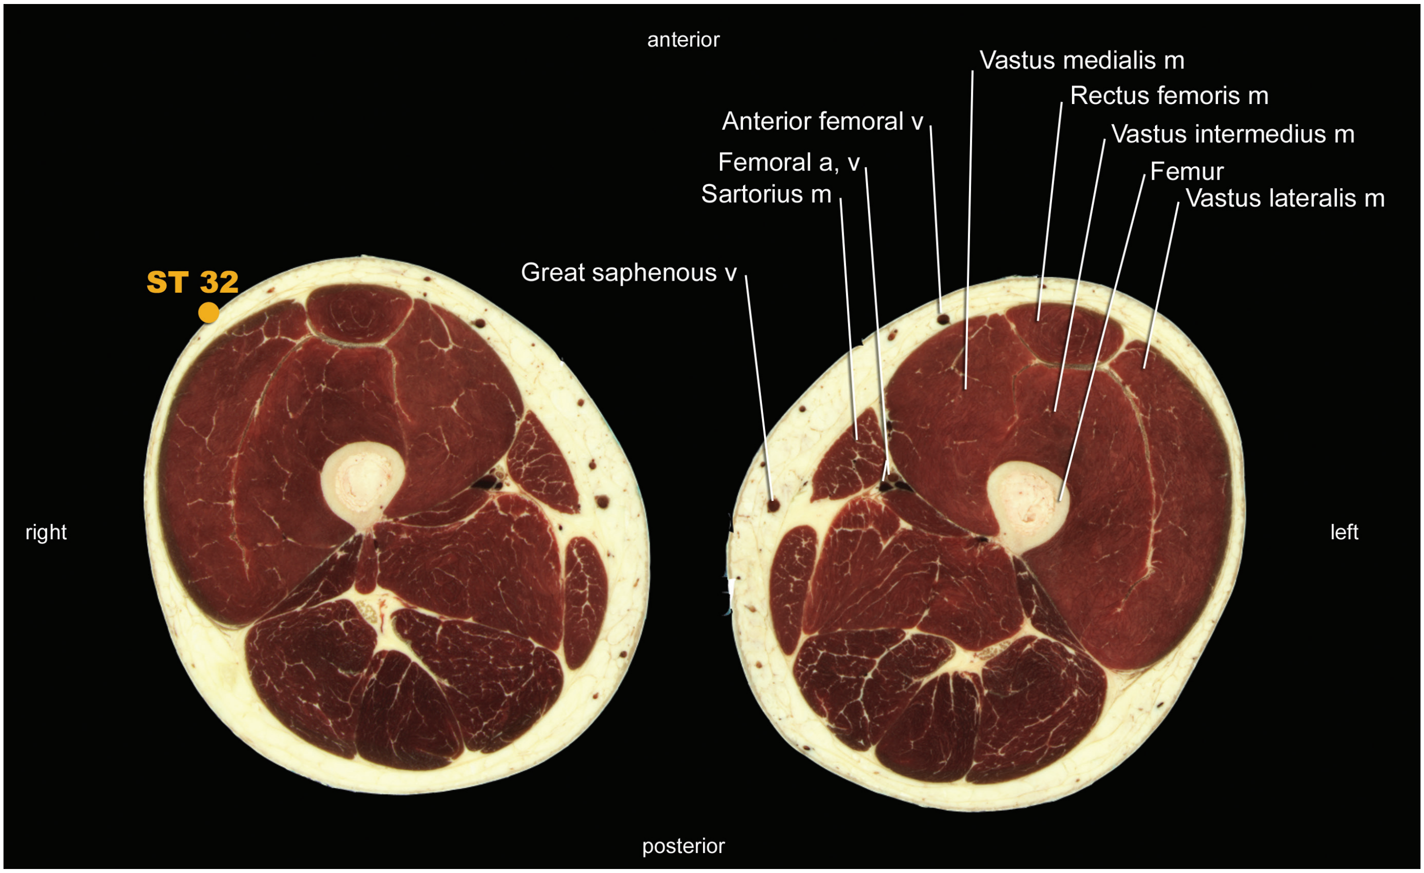

Figure 3-85. The cross section at ST 32 indicates the profound muscularity at this point. The underlying vastus lateralis muscle boasts the greatest muscle bulk of any of the quadriceps group and, as such, is responsible for a panoply of referred pain patterns, constituting a "hornet's nest" of problems, according to Travell and Simons. (Travell JG and Simons DG. *Volume 2. Myofascial Pain and Dysfunction. The Trigger Point Manual. The Lower Extremities.* Baltimore: Williams & Wilkins, 1983, p. 253.) Pain from myofascial trigger points in the vastus lateralis extends from the iliac crest to the lateral patella. Travell and Simons' nickname for the vastus intermedius muscle is "the frustrator" because its trigger points often elude direct palpation due to its central location. Pain patterns from vastus intermedius trigger points overlap with those of the vastus lateralis muscle. Both induce pain along the ST channel.

Vessels

- **Lateral circumflex femoral artery, descending branch:** Supplies the femoral head and lateral thigh musculature.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Pelvic somatic pain, anterior iliac region:** ST 32; palpate for myofascial trigger point contributors to palpatory tenderness, in addition to the vastus lateralis muscle, GB 26, GB 27, GB 28, GB 29; ST 36.
- **Pain, weakness, or paralysis of the legs (pelvic limbs) related to the femoral nerve distribution or midlumbar spinal segmental dysfunction:** ST 32,ST 36, Bafeng (web spaces between the toes), BL 23, BL 24, BL 25, GV 3, GV 4.

ST 33

Yin Shi "Yin Market"

On the anterior thigh, on the line connecting the ASIS with the superolateral angle of the patella, 3 cun proximal to the patella, along the lateral border of the rectus femoris muscle. ST 33 occurs midway between ST 32 and the superolateral patella.

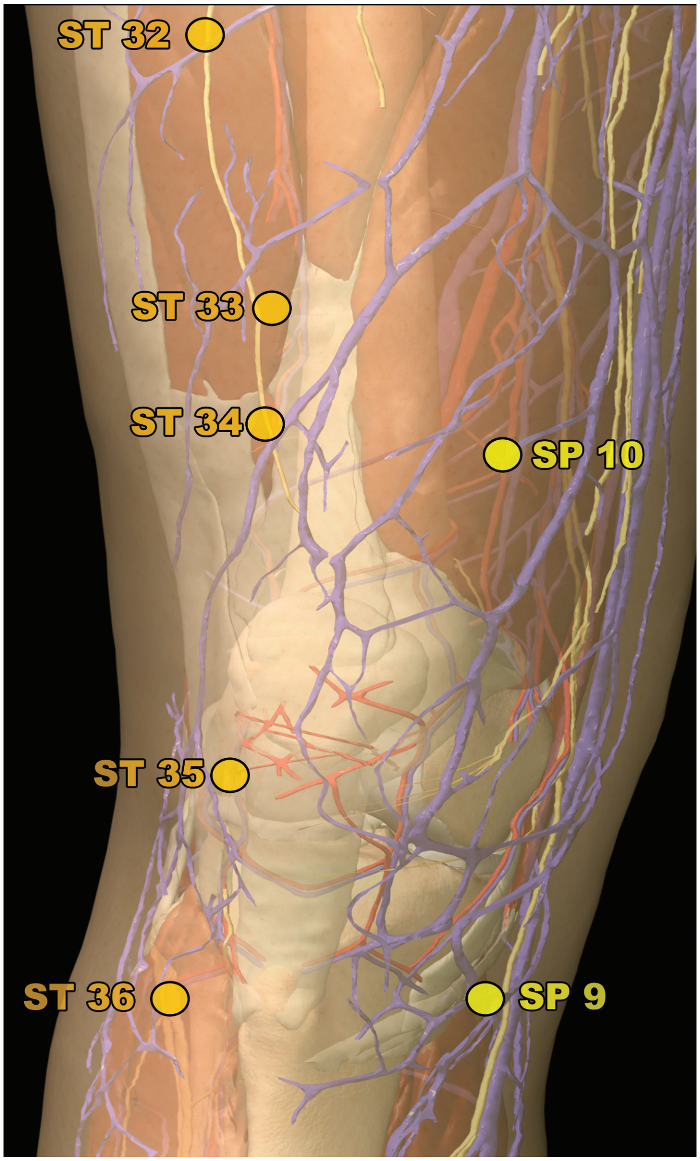

Figure 3-86. In Chinese medicine, climatic conditions of cold and damp (both "Yin" type pathogenic factors) are responsible for swelling and pain in the joint. These Yin pathogenic factors constitute a "Yin Market", i.e., the descriptive term for ST 33.

Muscles

- **Vastus lateralis muscle:** Extends the leg at the knee.
- **Rectus femoris muscle:** Extends the leg at the knee, and steadies the hip joint. Helps the iliopsoas muscle flex the thigh.

Clinical Relevance: A number of trigger points in the quadriceps group cause problems in the cranial thigh. Muscles affected by needling ST 33 depend on the depth and direction of needle insertion.

Nerves

- **Lateral femoral cutaneous nerve (L2, L3):** Provides sensation to the skin on the lateral and anterior thigh.
- **Femoral nerve (L2-L4):** Innervates the quadriceps femoris muscle group, which extends the leg at the knee. Also supplies the iliacus, pectineus, and sartorius muscles. The femoral nerve provides articular branches to the hip joint and the knee joint, and provides a number of cutaneous branches that serve the anteromedial thigh region. The femoral nerve terminates as the saphenous nerve, a cutaneous branch. The saphenous nerve supplies the skin and fascia of the anteromedial portions of the knee, leg, and foot.

Clinical Relevance: The femoral and lateral femoral cutaneous nerves govern strength and sensation, respectively, in the caudolateral thigh.

Vessels

- **Lateral circumflex femoral artery, descending branch:** Supplies the femoral head and lateral thigh musculature.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Knee pain, swelling, restriction in range of motion:** ST 33; palpate for myofascial trigger point contributors in the vastus lateralis muscle. Also evaluate ST 34 for tenderness to palpation, other trigger points in the region, and consider adding ST 35, ST 36, SP 9, SP 10, GB 34 for anterior knee pain.
- **Posterior knee pain:** ST 33, ST 34, and relevant KI, BL points.

ST 34

Liang Qiu "Ridge Mound", "Hill Ridge"

Above the knee, 2 cun proximal to the superolateral angle of the patella, along the lateral border of the tendon of the rectus femoris muscle. Because the height of the patella equals 2 cun, one can find ST 34 at the length of one patella above its superior border, along the line between the ASIS and the patella.

Muscles

- **Vastus lateralis muscle:** Extends the leg at the knee.
- **Rectus femoris muscle:** Extends the leg at the knee, and steadies the hip joint. Helps the iliopsoas muscle flex the thigh.

Clinical Relevance: A number of trigger points in the quadriceps group cause problems in the cranial thigh. Muscles affected by needling ST 34 depend on the depth and direction of needle insertion.

Nerves

- **Lateral femoral cutaneous nerve (L2, L3):** Provides sensation to the skin on the lateral and anterior thigh.
- **Femoral nerve (L2-L4):** Innervates the quadriceps femoris muscle group, which extends the leg at the knee. Also supplies the iliacus, pectineus, and sartorius muscles. The femoral nerve provides articular branches to the hip joint and the knee joint, and provides a number of cutaneous branches that serve the anteromedial thigh region. The femoral nerve terminates as the saphenous nerve, a cutaneous branch. The saphenous nerve supplies the skin and fascia of the anteromedial portions of the knee, leg, and foot.

Clinical Relevance: The femoral and lateral femoral cutaneous nerves govern strength and sensation, respectively, in the caudolateral thigh.

Vessels

- **Lateral circumflex femoral artery, descending branch**: Supplies the femoral head and lateral thigh musculature.

Clinical Relevance: Muscular compression and/or myofascial restriction in the anterolateral thigh may impede blood supply and drainage, facilitating the development and maintenance of myofascial trigger points in the region.

Indications and Potential Point Combinations

- **Anterior knee pain:** ST 34, ST 36, SP 10, SP 9. Consider myofascial trigger points referring to the knee, especially from the vastus lateralis (the "stuck patella" muscle), the rectus femoris (the "two-jointed puzzler"), the vastus intermedius (the "frustrator"), and the vastus medialis (the "buckling knee" muscle).
- **Leg pain or poor circulation in the pelvic limbs:** ST 34, after identifying the pain or impairment in circulation as originating from fascial restriction affecting the anterior pelvic limb. Release fascial restriction and trigger -point-generated tension. Add ST 36 as a distal point for cranial limb pain, or BL 40 for caudal limb pain.

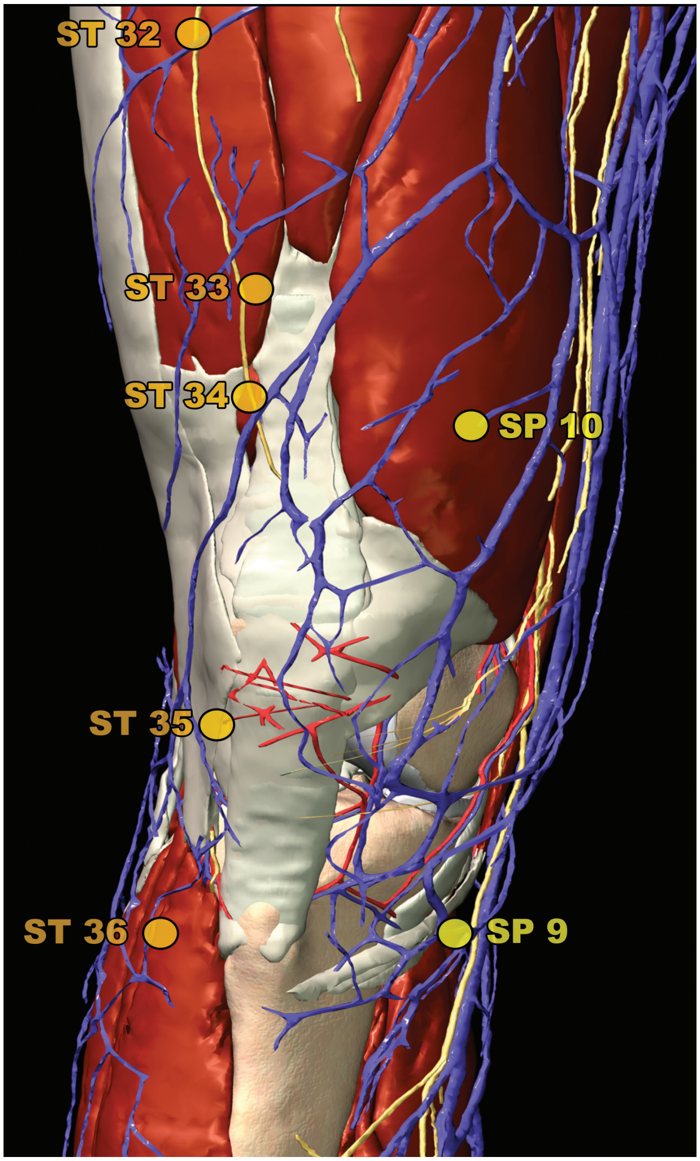

Figure 3-87. "Ridge Mound", or ST 34, sits at the lower limit of the mound produced by the vastus lateralis muscle.

Evidence-Based Applications

- Unilateral acupuncture for **advanced osteoarthritis of the knee** was effective as bilateral acupuncture, using SP 9, SP 10, ST 34, ST 36, and LI 4 on the ipsilateral hand.[1]
- Stimulation of ST 34 in geriatric individuals **improved gait performance** significantly better than a control point along the iliotibial band.[2] This is consistent with the finding that input from Group III- and Group IV-mediated afferent feedback through the femoral nerve influences the voluntary termination of exercise. Somatic afferent stimulation of the quadriceps muscle group may reduce peripheral fatigue and improve muscular adaptation to exercise.[1]

left
posterior

Figure 3-88. The suprapatellar bursa adjacent to ST 34 may help explain the point's indication for knee pain and arthritis. However, one should remain cautious when needling ST 34 so as not to cause suprapatellar bursitis.

ST 35

Du Bi "Calf's Nose"

In the depression below the patella and lateral to the patellar ligament, at approximately the level of the joint line of the knee.

Connective Tissues

- **Superficial infrapatellar bursa:** Sits between the patellar ligament and the skin, allowing mobility between the ligament and the skin.
- **Deep infrapatellar bursa:** Found at the lateral aspect of the patellar ligament, just proximal to the tibial tubercle. Allows for movement of the patellar ligament over the tibia.

Clinical Relevance: Disorders affecting the deep infrapatellar (also called retropatellar) bursa include calcification, inflammation, septic bursitis, gout, and traumatic hemorrhage.[2] The deep infrapatellar bursa can cause anterior knee pain in patients following patellectomy. Scarring of this bursa can lead to infrapatellar contraction syndrome. Acupuncture treatment of pain from infrapatellar bursitis can involve ST 35 due to its anatomic proximity to infrapatellar bursae.

Nerves

- **Anterior cutaneous branches of femoral nerve (L2-L4):** Supplies the skin on the anterior and medial parts of the thigh.
- **Infrapatellar branch of saphenous nerve:** The infrapatellar branch of the saphenous nerve provides cutaneous sensation to the anterior aspect of the knee as well as sensation to the anterior inferior knee capsule.
- **Recurrent articular nerve from common fibular (peroneal) nerve (from sciatic):** Supplies the knee joint. Branches of this nerve extend to the proximal anterior tibial muscle as well as the superior tibiofibular and knee joints.[3]

Clinical Relevance: Injury of the infrapatellar branch of the saphenous nerve may lead to anterior knee pain following various surgical procedures to the knee, including intramedullary nailing during repair of tibial shaft fracture. This neuropathic pain, including hyperalgesia, dysesthesia, and allodynia, may persist despite the absence of peripheral noxious stimulation or ongoing inflammation. In addition, surgical trauma may result in neuroma formation and reflex sympathetic dystrophy. Acupuncture may alleviate this neuropathic pain through local and regional influences.

Fibular intraneural cysts may affect motor and/or sensory branches of the fibular nerve. A cystic branch to the patellar tendon may cause disturbances in the region of ST 35.

Vessels

- **Lateral genicular anastomosis, joining the superior and lateral genicular arteries on the lateral aspect of the knee:** The arteries supplying the knee joint (and which form the arterial anastomoses around the knee) include genicular branches of the popliteal and femoral arteries as well as posterior recurrent branches of the anterior tibial recurrent and circumflex fibular arteries.

Clinical Relevance: Each of the contributing vessels to the genicular anastomoses provides the major source of blood to its respective region and supplies blood to the bony, ligamentous, meniscal, and regional soft tissues. Acupuncture at ST 35 may improve blood flow to regions in which vascular support has been impaired.

Indications and Potential Point Combinations

- **Knee joint pain:** ST 35, often combined with Xiyan (on medial border of patellar tendon) for knee problems. Together, these are known as the "Eyes of Knee."
- **Superficial infrapatellar bursitis ("clergyman knee"):** ST 35, Xiyan, ST 34, ST 36, SP 9, SP 10.

Evidence-Based Applications

- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis**, using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[1]
- Electroacupuncture (EA) and transcutaneous electrical nerve stimulation applied to painful **osteoarthritic knees** effectively reduced pain; EA also improved the "Timed Up-and-Go Test" (TUGT) scores.[5]

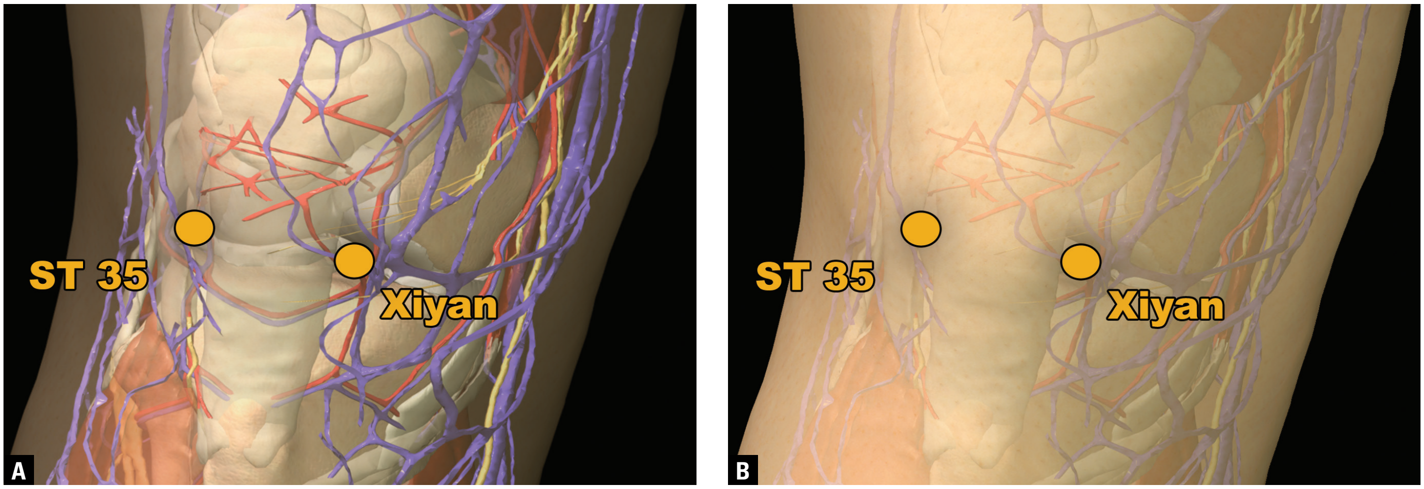

Figure 3-89A and B. When the knee extends, two depressions appear on either side of the patellar ligament, resembling the nose of a calf. Another term for this appearance is "Xiyan", meaning "Eyes of the Knee". ST 35 refers to the lateral eye of the knee.

- Laser acupuncture at ST 35 reduced pain in patients with **osteoarthritis in the knee.**[6]

ST 36

Zu San Li "Leg 3 Miles"

Below the knee, 3 cun distal to the apex of the patella and one finger-breadth lateral to the tibial tuberosity. Another point location method involves first finding GB 34; ST 36 lives 1 cun below GB 34 and 1 fingerbreadth lateral to the tibial tuberosity, or anterior crest of the tibia.

Connective Tissues

- **Interosseous membrane (IOM):** Separates the leg into an anterior and posterior compartment.

Clinical Relevance: The IOM of the leg and forearm share striking similarities, in light of the recognition that ankle and wrist injuries, respectively, simultaneously cause problems in the IOM, knee or elbow, and nerves that course between the tibia/fibula and radius/ulna.[75] Acupuncture at points such as ST 36 may improve the function and facilitate the repair of injured nerves, i.e., the fibular nerve in this case.

Muscles

- **Tibialis anterior muscle:** Inverts the foot and dorsiflexes the ankle.
- **Extensor digitorum longus muscle:** Dorsiflexes the ankle and extends the lateral four pedal digits.

Clinical Relevance: Muscle afferent activation in the anterior tibial and extensor digitorum longus muscles can affect organ function through a variety of neurologic connections, reflexes, and possibly also the release of "chaperone" proteins and their phosphorylation. Specifically, heat shock proteins (HSP), released after fatiguing stimulation of muscles in the anterior compartment of the crus, may constitute one potential pathway that affects cytoskeletal assembly and remodeling. Circulating HSP may alter metabolism and function of distant structures, including respiratory muscles, kidney, and brain.[76]

From a myofascial perspective, trigger point pathology in the anterior tibialis muscle at ST 36 leads to a descending pain referral pattern that proceeds directly down the shaft of the tibia, over the anterior ankle joint, and centered substantially over and within the great toe.

Manual acupuncture needle stimulation delivered to ST 36 activates every type of muscle afferent in the anterior tibialis muscle; i.e., groups I, II, III, and IV.[77] This finding provides insight into why stimulating ST 36 imparts such a wide variety of physiologic responses.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular nerve (L4, L5, S1):** Supplies skin on the anterior ankle and dorsum of the foot (except for the interdigital cleft). Also supplies the fibularis (peroneus) longus and brevis muscles.
- **Lateral sural cutaneous nerve (L4, L5, S1; branch of common fibular):** Supplies skin on the posterolateral portion of the lower leg.
- **Recurrent articular nerve from common fibular nerve:** Supplies the knee joint.

Clinical Relevance: Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[78]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of sympathetic nervous system activity.[79,80] It is also important to note that, while acupuncture at ST 36 can facilitate recovery from fibular nerve injury,[81] too vigorous and deep needling could also injure the nerve.[82]

Afferent input from the fibular nerve at ST 36 and ST 37 ascends to the nucleus tractus solitarius (NTS) and dorsal motor nucleus of the vagus nerve (DMNV); EA at both of these sites regulates gastric motility.[83,84] However, activation of nerves at ST 37 demonstrated a less pronounced effect.

Compared to stimulation at ST 25, ST 36 activates the DMNV, while ST 25 influences activity in the rostral ventrolateral medulla (RVLM).[85] This emphasizes how acupuncture induces the regional specific effects that can preferentially modulate parasympathetic or sympathetic activity, respectively.

Vessels

- **Anterior tibial recurrent artery (ATRA):** Connects the anterior tibial artery to the genicular anastomosis and supplies structures in this region, including the lateral tibial condyle.[85] That ATRA anastomoses with the inferior lateral genicular artery (a branch of the popliteal artery) with branches surrounding the lateral intercondylar tubercle and the femoro-tibial joint capsule.

Clinical Relevance: The ATRA branches off of the anterior tibial artery (ATA) in the vicinity of ST 36. Thus, improving circulation

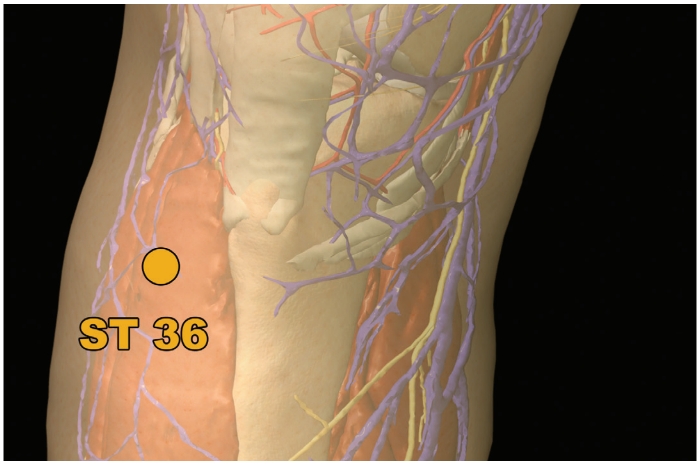

Figure 3-92. ST 36, "Leg Three Li", takes the lead for the amount of research performed on a single acupuncture point as well as its frequency of use in treatment. Its capacity to promote homeostasis makes it both an ancient and modern favorite. The name "Leg Three Li" implies its capacity to allow patients to walk longer distances with "li" equating to approximately 360 meters. Alternatively, "Leg Three Li" may simply indicate how one locates the point 3 cun, or 3 fingerbreadths, distal to the inferior border of the patella.

through acupuncture at ST 36 not only influences multiple levels of nerve function, but it also may improve hemodynamics of knee and surrounding structures. Arthroscopy of the joint, tibial fracture repair, and sub-meniscal arthrotomy may damage these fine vessels, requiring support through neuro- and circulatory modulation by means of acupuncture and related techniques.

Indications and Potential Point Combinations

- **As one of the most important acupuncture points in the body, ST 36 is worth considering as a supportive adjunct for nearly every condition. For some conditions, such as gastrointestinal motility disorders, its significance to modulate function makes its inclusion paramount. Its effects extend from the knee and pelvic limb as a whole to the lumbosacral spinal cord segments, brainstem (nucleus tractus solitarius and dorsal motor nucleus of the vagus nerve), limbic system, psychoneuroimmunologic regulation, and beyond.**
- **Gastrointestinal problems:** appendicitis, nausea and vomiting, gastritis, pain, diarrhea, constipation, dyspepsia, gastric ulcer: ST 36, BL 21, CV 12, PC 6.
- **Hepatitis and cholecystitis:** ST 36, GB 24, LR 14, CV 12.
- **All pain problems:** Combine with any pain management protocol to help counter the sympathetic overactivation associated with both acute and chronic pain.
- **Lower leg pain:** ST 36, pertinent trigger points. Specifically, myofascial trigger points in the tibialis anterior muscle refer to the cranial ankle (ST 41) and the big toe.
- **Fatigue, dizziness:** ST 36, GB 20, BL 10, GV 20.
- **Seizures:** ST 36, GB 20, Sishencong (GV 20 plus the four extra points 1 cun in either cardinal direction from GV 20; alternatively, GV 20 plus BL 7, BL 8). Add HT 7 for stress-induced seizures; LR 3 for nighttime seizures.
- **Asthma and breathing problems:** ST 36, BL 13, BL 23, LU 1, LU 2, LU 5, CV 17.
- **Immune stimulation:** ST 36, LI 4, LI 11, SP 6, GV 14.
- **Hypertension:** ST 36, ear points in the auricular branch of the vagus nerve distribution.
- **Hemiplegia:** ST 36, LI 4, points related to dysfunctional musculature to stimulate nerve function and release contraction, GV 20.
- **Metabolic disorders:** ST 36, ST 37, LI 4, GV 20, BL 22, BL 23; target additional points to specific dysfunction.

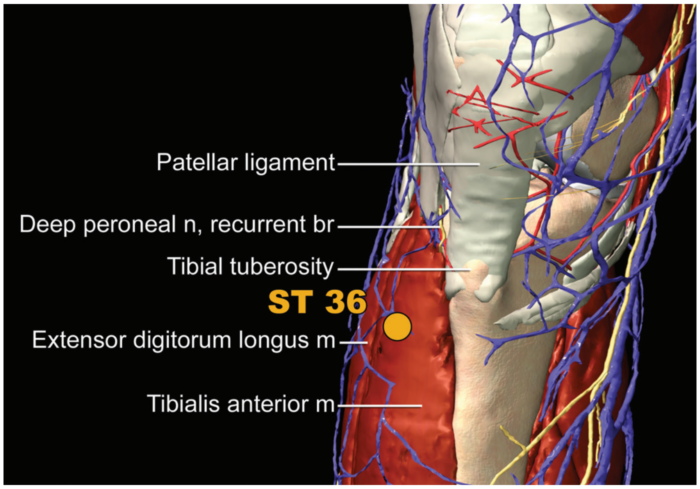

Figure 3-93. ST 36's location deep within the tibialis anterior muscle gives the acupuncturist ample opportunities to stimulate many types of afferents residing in this region. Stimulated somatic afferents in muscle from Groups I, II, III, and IV elicit widespread and diverse effects on the autonomic and central nervous systems. (Kagitani F, Uchida S, Hotta H, et al. Manual acupuncture needle stimulation of the rat hindlimb activates groups I, II, III and IV single afferent fibers in the dorsal spinal roots. Japanese Journal of Physiology. 2005;55(3):149-155.) Too, a rich supply of autonomic fibers from genicular arterial and venous anastomoses provide means of improving blood supply and drainage.

Evidence-Based Applications

Note: The number of studies on the physiology and clinical benefits of ST 36 seems endless and ever-growing. What appears below constitutes a mere snapshot of the times ST 36 has been tested clinically and experimentally. The main thing to remember regarding ST 36 is its capacity to neuromodulate not only from a musculoskeletal/somatic perspective but also in an autonomic/parasympathomimetic manner.

- Regarding the effects of acupuncture on canine **gastric motility** using ST 36, ST 40, ST 41, ST 42, ST 45, BL 12, or CV 12, only stimulation of ST 36 or BL 21 promoted gastric motility, whereas motility decreased with CV 12 stimulation. No significant changes in motility occurred after acupuncture at ST 40, ST 41, ST 42, or ST 45.[1]
- Acupuncture at LI 4, ST 36, SP 6, and SP 9 **reduced discomfort** and anxiety in patients undergoing colonoscopy.[2]
- Acupuncture at LI 4, LI 11, LR 3, SP 6, ST 25, ST 27, and ST 36 improved well-being and reduced bloating in patients with **irritable bowel syndrome.**[3]
- Transcutaneous electrical nerve stimulation (TENS) at LI 4, LU 10, BL 57, and ST 36 effectively **reduced rectal hypersensitivity** in diarrhea-predominant **irritable bowel syndrome.**[4]
- Electroacupuncture at ST 36 and PC 6 **enhances gastric motility** by affecting the migrating myoelectrical complex.[5]
- Electroacupuncture at ST 36 altered the expression of nitric oxide synthase in the hypothalamus and adrenal gland, conferring **protective effects against ulcer** in a rat model.[6]
- Electroacupuncture simultaneously at both PC 6 and ST 36 has a synergistic effect on **gastric myoelectrical activity.**[7]
- Moxibustion (using *Artemisia vulgaris*) at CV 12, ST 25, and ST 36 was effective in **preventing acute gastric lesions** induced by indomethacin in rats.[8]
- Acupuncture at ST 36, CV 12, and PC 6 served as an effective short- and medium-term treatment for **chronic idiopathic dyspepsia**, with fewer adverse effects and longer effectiveness than treatment with the prokinetic agent, domperidone.[9]
- Acupuncture at LI 4, ST 36, PC 6, LR 3, CV 12, CV 17, and CV 22 successfully **treated sleep-related laryngospasm with gastroesophageal reflux**, refractory to current medical treatment; results were maintained at a 1-year follow-up assessment, and no evidence of reflux was detected upon repeated upper gastrointestinal study.[10]
- **Hypoglycemic** effects of ST 36 may involve serotonin.[11]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[12]

- Acupuncture at ST 36 exerted **dual effects (i.e., either stimulatory or inhibitory) on gastric motility depending on pre-treatment motility.** Stimulatory effects were mediated via vagal efferent and opioid pathways.[13]

- Acupuncture at ST 36 and LR 3 significantly **reduced liver injury** markers when rats were acupunctured after, but not before, CCL_4-induced hepatotoxicity.[14]

- Electroacupuncture at ST 36 influences **adrenal function.**[15]

- Acupuncture at LR 3, SP 6, SP 9, and ST 36 benefited patients with **chronic painful peripheral diabetic neuropathy.**[16]

- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis.**[17]

- Acupuncture and electroacupuncture at BL 17, BL 17.5, BL 20, BL 23, ST 36, and SP 6 effectively regulated levels of glucagon and immune factors, reduced blood coagulability, improved microcirculation, and heightened insulin sensitivity in **Type-II diabetics.**[18]

- Acupuncture at BL 32, TH 6, and ST 36 improved **constipation due to diabetes mellitus** in a report on a series of cases.[19]

- Electroacupuncture at ST 36 enhanced the regularity of gastric myoelectric activity in **diabetic patients with gastric dysrhythmia.**[20]

- Electroacupuncture at PC 6 and ST 36 helps control **chemotherapy-induced emesis.**[21]

- Acupuncture at ST 36 and GB 34 may exert their **hypotensive effects** by decreasing renin secretion.[22]

- Electroacupuncture at ST 36 **lowers blood pressure** in dogs, possibly in part by acting on opioid receptors on blood vessels.[23]

- Following **acute myocardial infarction,** patients receiving acupuncture at CV 14, CV 17, ST 36, PC 6, and SP 6 demonstrated the following changes: reduced blood viscosity and myocardial oxygen consumption, improved microcirculation and left ventricular function, improved collateral circulation, and reduced the area of infarction.[24]

- Electroacupuncture at ST 36 and ST 38 potentiated the **hypotensive effect** of nitroglycerin, which helped achieve the target mean arterial pressure during microscope middle ear surgery under general anesthesia with halothane.[25]

- Acupuncture at ST 36, BL 15, BL 20, HT 5, and PC 6 reduced the number of attacks per week in **angina** patients and reduced ST-segment depression during exercise, possibly indicating protection of the myocardium from ischemia.[26]

- A case report indicated that acupuncture at ST 36, KI 3, and LR 3 produced dramatic improvement in **chronic venous ulceration.**[27]

- Acupuncture at LI 4, LI 11, B 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[28]

- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud's syndrome**, demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[29]

- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with **keratoconjunctivitis sicca** (KCS, or dry eye).[30]

- The four points LI 11, SP 10, SP 6, and ST 36 treat **acute urticaria.**[31]

- May improve hypertension by **benefiting microcirculation;** studied with LI 11, LR 3, and LI 4.[32]

- Case report of improvement with acupuncture at LR 3, KI 3, SP 6, and ST 36 for **sweating associated with malignancy,** unresponsive to other measures.[33]

- Acupuncture-like transcutaneous nerve stimulation at SP 6, ST 36, LI 4, and CV 24 improves whole saliva production in patients with radiation-induced **xerostomia** in head-and-neck cancer patients treated with radical radiotherapy.[34]

- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4,

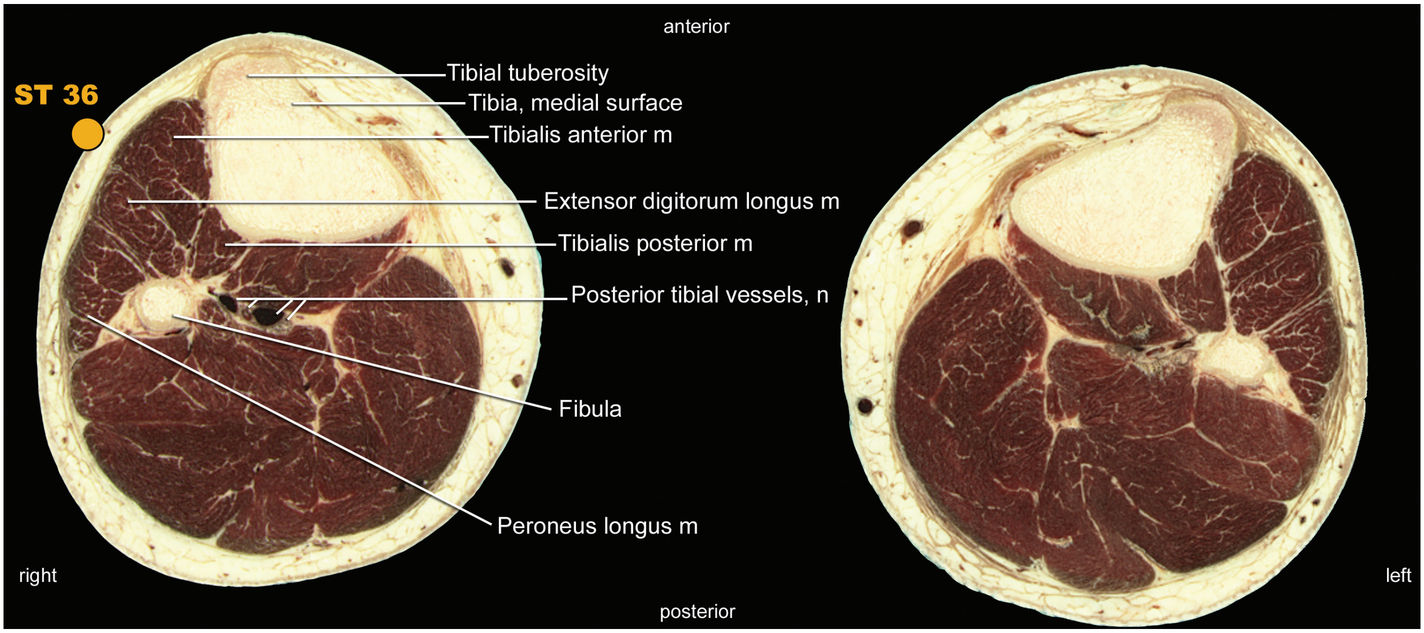

Figure 3-94. A needle inserted into ST 36 could penetrate either the tibialis anterior muscle, the extensor digitorum longus muscle, or both, depending on the angle of entry, as demonstrated by this cross section. That is, directing the needle toward the tibial tuberosity would select the tibialis anterior. A right-angle insertion method would impact the intermuscular cleavage plane, while a more lateral approach would target more the extensor digitorum longus muscle.

LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[35]

- Both manual acupuncture and low-frequency EA to LI 4, ST 4, ST 7, ST 36, HT 7, SP 6, and KI 5 caused significant increases in local blood flow overlying the parotid gland, suggesting a mechanism for increased salivary flow in **xerostomia** patients.[36]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with **Sjögren's syndrome.**[37]
- Acupuncture stimulation of GV 14 caused hypothermia via a decrease in metabolic rate, an increase in cutaneous circulation on the back, and perspiration. In contrast, acupuncture stimulation of PC 6 or ST 36 produced a slight **hyperthermia,** putatively due to a decrease in cutaneous circulation.[38]
- Acupuncture at SP 6 produced a strong vasoconstriction in the ipsilateral leg and a slight vasoconstriction in the contralateral leg with no change in the arms Stimulation of ST 36 produced a **superficial vasoconstriction** in the skin of both legs but no change in the arms. Stimulation of PC 6 or LI 11 caused ipsilateral vasoconstriction in the arms only. This information suggests a topographical representation in the neural segments responsible for the change in sympathetic activity.[39]
- Repeated acupuncture at ST 36, LI 11, SP 10, and GV 14 significantly decreased leukocyte and lymphocyte values in healthy humans, although cortisol and norepinephrine plasma levels remained unchanged. The mechanism whereby acupuncture affected **leukocyte circulation** was unknown.[40]
- A case series involving acupuncture at ST 36 supported its effectiveness in treating **leukopenia.**[41]
- Electroacupuncture at ST 36 **enhanced splenic natural killer (NK) cell cytotoxicity,** interleukin-2, and interferon-γ in rats.[42,43] The anterior hypothalamus may be at least partly responsible for modulating NK cell activity.[44]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with **Sjögren's syndrome.**[45]
- A case series evaluating acupuncture for **poison ivy contact dermatitis** reported effectiveness with the acupuncture points SP 10, LI 11, and ST 36.[46] These points were also effective in reducing the severity and preventing recurrences of **herpes simplex infections**[47] and in clearing **psoriasis lesions.**[48]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia (OAT syndrome).**[49]
- Needling GB 34, ST 36, SP 6, and BL 67 may help **decrease the need for labor induction and cesarean section.**[50]
- Electroacupuncture (at ST 29 and TH 5 to LI 4) with manual acupuncture at GV 20 and ST 36 serve as an effective **analgesic during oocyte aspiration;** these analgesic effects equal those of conventional analgesics.[51] Neuropeptide Y (NPY) concentrations in follicular fluid were higher in the electroacupuncture group than in the medication group; NPY may be important for human ovarian steroidogenesis.[52]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[53]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in **improvement in sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[54]
- Acupressure at KI 1, GB 34, ST 36, and SP 6 helped relieve **fatigue** in patients with **end-stage renal disease.**[55]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis** in women.[56]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[57]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 7, ST 6, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[58]
- Unilateral acupuncture for advanced **osteoarthritis of the knee** was effective as bilateral acupuncture, using SP 9, SP 10, ST 34, ST 36, and LI 4 on the ipsilateral hand.[59]
- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis,** using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[60]
- Acupuncture at LR 3, SP 6, ST 36, CV 12, LI 4, PC 6, GB 20, GB 14, Taiyang, and GV 20 provided greater effectiveness in **prophylaxis of migraine** compared to flunarizine.[61]
- **HIV-related peripheral neuropathy** improved with electroacupuncture on BL 60, ST 36, KI 1, and LR 3.[62]
- Electroacupuncture at ST 36 and ST 44 **affected monoamine (serotonin, dopamine, and norepinephrine) levels in the corpus striatum of obese rats** and increased ATPase activity in the striatum.[63]
- EA at GV 2, GV 14, GV 20, GV 24.5, prevented tissue shrinkage of the dorsal hippocampus, basolateral nucleus of the amygdala, substantia nigra, and perirhinal cortex. EA at ST 36 and SP 6 prevented tissue shrinkage in all of the aforementioned regions except for the dorsal hippocampus. EA to GV 2 + GV 14 + GV 20 + GV 24.5 or ST 36 + SP 6 reduced the cognitive deficits in pilocarpine-epileptic rats. Administration of p-chlorophenylalanine, a compound that depletes serotonin, negated the behavioral and some of the histologic changes due to EA. This suggests that the functional recovery exhibited by the rats may have been influenced through serotonergic pathways affected by acupuncture and subsequent **neuroprotective benefits.**[64]
- Electroacupuncture at ST 36 and ST 44 increased the frequency of spontaneous discharges of neurons in the ventromedial nucleus of the hypothalamus (VMH) in obese rats. It also increased the levels of tyrosine, dopamine, tryptamine, while lowering serotonin levels. This suggested that acupuncture may be beneficial for **weight reduction** by influencing the satiety center – the VMH.[65]
- Electroacupuncture at GV 2, GV 14, and ST 36 markedly **suppressed cortical epileptiform discharges** in rats. Possible mechanisms involved include alterations of opioid, serotonin, and

gamma-aminobutyric acid (GABA) levels and recurrent inhibition of the cortex and hippocampus.[66]

- Acupuncture at LI 4 and ST 36 **activated the hypothalamus and nucleus accumbens.** Both of these brain structures are important in mediating acupuncture analgesia. Acupuncture at LI 4 and ST 36 **deactivated areas within the limbic system,** including the rostral part of the anterior cingulate cortex, amygdala formation, and hippocampal complex. Limbic deactivation may play a role in acupuncture analgesia by affecting pain perception – in particular, its affective-cognitive aspect.[67]

- Electroacupuncture at ST 36 + SP 6 was compared to GB 34 + BL 57, in order to study differences in brain activation from acupuncture points located in the same spinal segments. Both overlapping and distinct cerebral response patterns from stimulation of the two pairs were observed. Both pairs of points (ST 36/SP 6 and GB 34/BL 57) activated the primary and secondary somatosensory areas, insula, ventral thalamus, parietal Brodmann Area 40, temporal lobe, putamen, and cerebellum; both deactivated the amygdala. However, ST 36/SP 6 **specifically activated the orbital frontal cortex and deactivated the hippocampus,** while GB 34/BL 57 activated the dorsal thalamus and inhibited the primary motor area and premotor cortex. These cerebral response differences may help explain why ST 36/SP 6 is indicated more for visceral disorders and pain while GB 34/BL 57 are important points for modulation of muscle and tendon function and motor output.[68]

- **Electroacupuncture at ST 36 (especially at low frequency) produced more widespread fMRI signal increase than manual acupuncture.** Hemodynamic signal increases from acupuncture were noted in the anterior insula, while decreases were noted in limbic and paralimbic structures: the amygdala, anterior hippocampus, subgenual cortex, retrosplenial cingulate cortex, ventromedial prefrontal cortex, frontal pole, and temporal pole. Electroacupuncture, but not manual acupuncture, produced a significant signal increase in the anterior middle cingulate cortex. Only low frequency (i.e., 2 Hz) electroacupuncture produced a signal increase in the pontine raphe area. These findings are concordant with those of other researchers indicating that the limbic system plays an important role in mediating the effects of acupuncture on the central nervous system.[69]

- Input from ST 36 converges on the **nucleus tractus solitarius (NTS),** which may account for the autonomic effects of stimulating this point.[70]

- Pre-injury electroacupuncture at GB 20 or ST 36 can partly regulate the lipid peroxidation occurring as a consequence of **cerebral ischemia.**[71]

- Electroacupuncture at ST 36 or GB 20 may increase thioredoxin expression which could minimize oxidative modifications of thiol groups of surrounding proteins, thereby helping reduce oxidative damage following **brain ischemia.**[72]

- Acupuncture at CV 17, CV 12, CV 6, ST 36, and SP 10 conferred protective effects on **cognitive impairments** caused by multi-infarction dementia in rats, suggesting it may benefit patients with vascular dementia.[73]

- Neuroanatomical tracers have demonstrated commonality of central nervous system cell groups in the brain that control the stomach and the limb at ST 36. Overlapping neurons showed up in the dorsal motor nucleus of the vagus nerve, the nucleus raphe magnus, the nucleus gigantocellularis, the locus coeruleus, and hypothalamic nuclei, in addition to several other locations.[74]

ST 37

Shang Ju Xu "Upper Great Hollow"

On the anterolateral aspect of the leg, 3 cun below ST 36 or 6 cun below ST 35; one finger-breadth lateral to the anterior margin of the tibia.

Connective Tissues

- **Interosseous membrane (IOM):** Separates the leg into an anterior and posterior compartment.

Clinical Relevance: The IOM of the leg and forearm share striking similarities, in light of the recognition that ankle and wrist injuries, respectively, simultaneously cause problems in the IOM, knee or elbow, and nerves that course between the tibia/fibula and radius/ulna.[2] Acupuncture at points such as ST 37 may improve the function and facilitate the repair of injured nerves, i.e., branches of the fibular nerve in this case.

Muscles

- **Tibialis anterior muscle:** Inverts the foot and dorsiflexes the ankle.
- **Extensor digitorum longus muscle:** Dorsiflexes the ankle and extends the lateral four pedal digits.

Clinical Relevance: Muscle afferent activation in the anterior tibial and extensor digitorum longus muscles can affect organ function through a variety of neurologic connections, reflexes, and possibly also the release of "chaperone" proteins and their phosphorylation. Specifically, heat shock proteins (HSP), released after fatiguing stimulation of muscles in the anterior compartment of the crus, may constitute one potential pathway that affects cytoskeletal assembly and remodeling. Circulating HSP may alter metabolism and function of distant structures, including respiratory muscles, kidney, and brain.[3]

From a myofascial perspective, trigger point pathology in the anterior tibialis muscle at ST 36 and ST 37 leads to a descending pain referral pattern that proceeds directly down the shaft of the tibia, over the anterior ankle joint, and centered substantially over and within the great toe.

Trigger point provocation in the extensor digitorum longus muscle near ST 37 can cause pain to radiate from the mid-crus down the dorsum of the foot to digits II through IV.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular nerve (L4, L5, S1):** Supplies skin on the anterior ankle and dorsum of the foot (except for the interdigital cleft). Also supplies the fibularis (peroneus) longus and brevis muscles.
- **Lateral sural cutaneous nerve (L4, L5, S1; branch of common fibular):** Supplies skin on the lateral lower leg.

Clinical Relevance: Stimulation of the fibular nerve with functional electrical stimulation (which possesses similar mechanisms of action to electroacupuncture) reduces foot drop and increases walking speed in patients with spastic paraparesis.[4]

Fibular nerve connections to the brain and spinal cord produce autonomic neuromodulation and pro-homeostatic influences when activated. The effects commonly involve reduction of

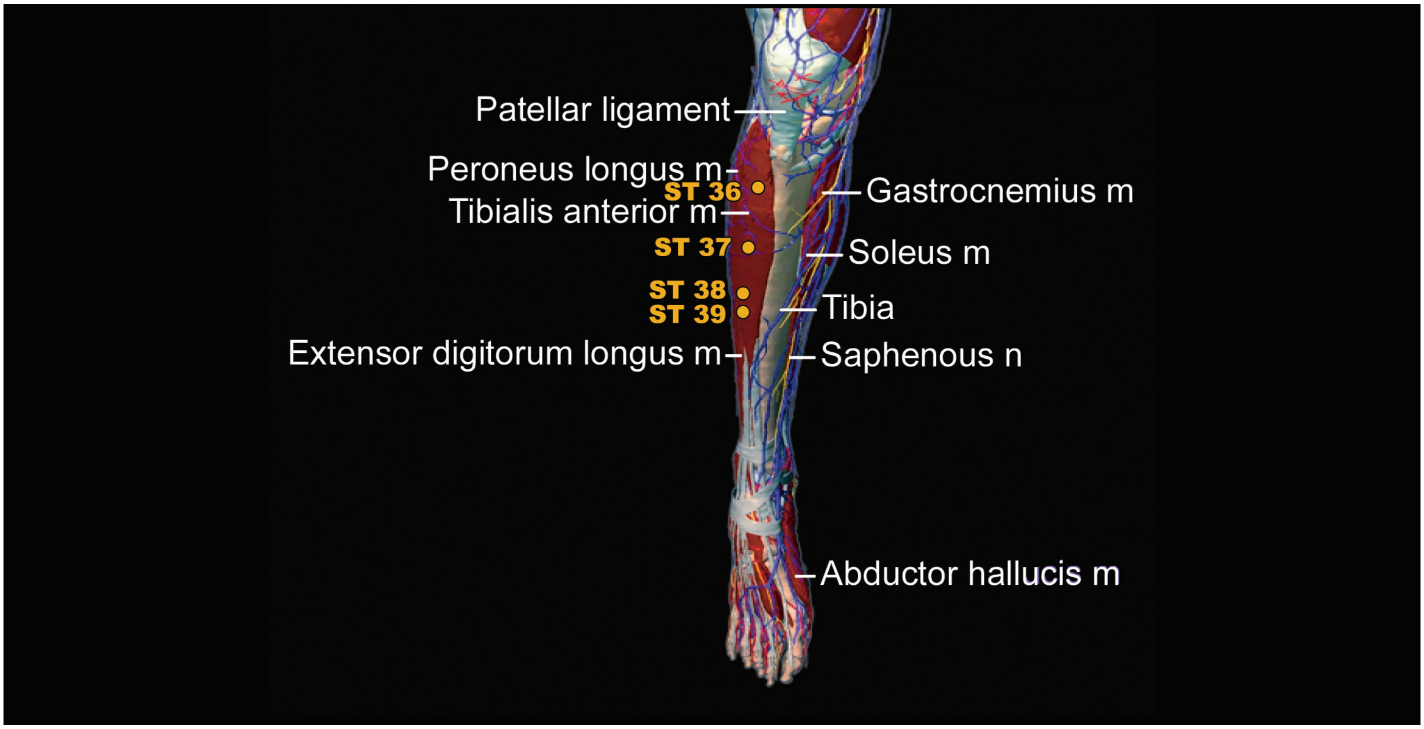

Figure 3-95. ST points on the anterior crus relate to the deep peroneal (fibular) nerve, and, as such, share common indications related to digestion. That is, they connect to the nucleus tractus solitarius in the brainstem but may have differing amplitudes of effects thereon.

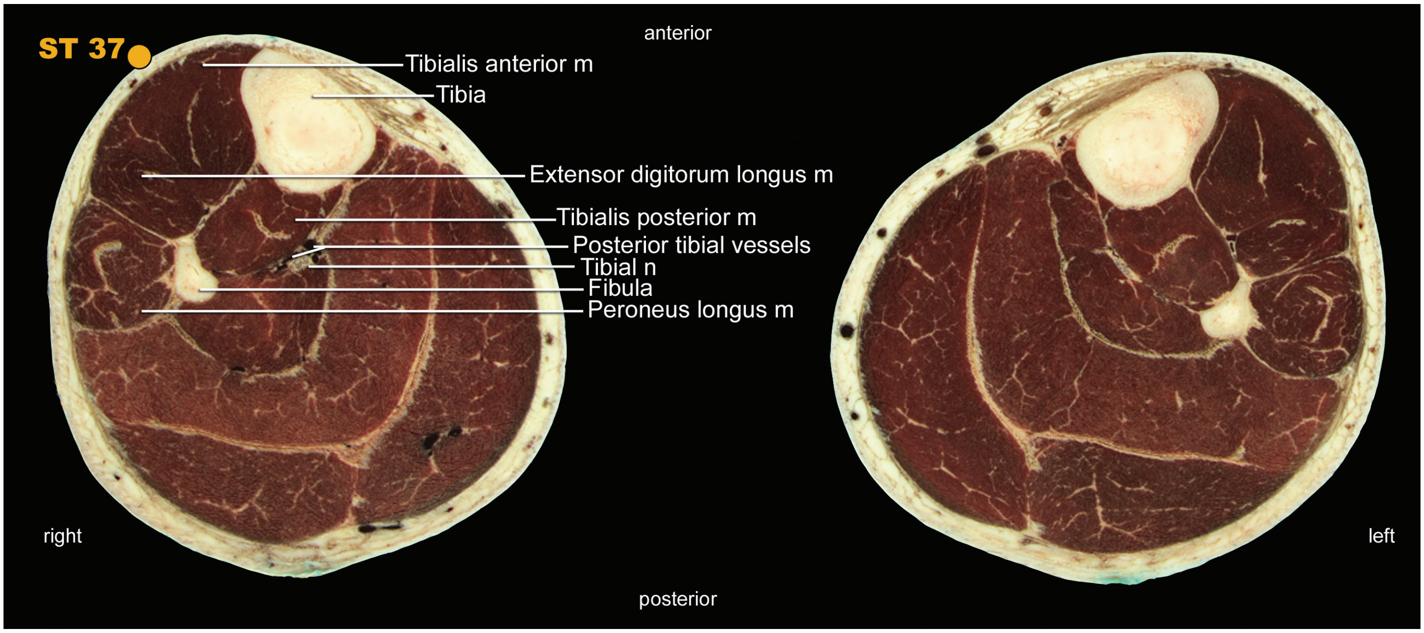

Figure 3-96. ST 37, the "Upper Great Hollow", compares to ST 39, the "Lower Great Hollow", connoting the gulley that sometimes forms along the myofascial cleavage plane between contracting anterior tibialis and extensor digitorum muscles on the anterolateral shin.

sympathetic nervous system activity.[5,6] It is also important to note that, while acupuncture at ST 36 (and, likely, ST 37 as well) can facilitate recovery from fibular nerve injury,[7] too vigorous and deep needling could also injure the nerve.[8]

Afferent input from the fibular nerve at ST 36 and ST 37 ascends to the nucleus tractus solitarius (NTS) and dorsal motor nucleus of the vagus nerve (DMNV); EA at both of these sites regulates gastric motility.[9,10] However, activation of nerves at ST 37 demonstrated a less pronounced effect.

Vessels

- **Anterior tibial artery (ATA):** Distributes blood to the anterior compartment of the leg.

Clinical Relevance: Inferolateral arteries such as the ATA are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[11] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Indications and Potential Point Combinations

- **Diarrhea:** ST 37, ST 36, SP 6, LI 4.
- **Abdominal pain and distension:** ST 37, ST 36, CV 10, CV 12.

Evidence-Based Applications

Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[1]

ST 38

Tiao Kou "Tight Mouth", "Ribbon Opening"

On the anterolateral leg, 8 cun below ST 35 or 8 cun above the lateral malleolus (i.e., halfway between), one finger-breadth lateral to the anterior margin of the tibia.

Connective Tissues

- **Interosseous membrane (IOM):** Separates the leg into an anterior and posterior compartment.

Clinical Relevance: The IOM of the leg and forearm share striking similarities, in light of the recognition that ankle and wrist injuries, respectively, simultaneously cause problems in the IOM, knee or elbow, and nerves that course between the tibia/fibula and radius/ulna.[3] Acupuncture at points such as ST 38 may improve the function and facilitate the repair of injured nerves, i.e., branches of the fibular nerve in this case.

Muscles

- **Tibialis anterior muscle:** Inverts the foot and dorsiflexes the ankle.
- **Extensor digitorum longus muscle:** Dorsiflexes the ankle and extends the lateral four pedal digits.

Clinical Relevance: Muscle afferent activation in the anterior tibial and extensor digitorum longus muscles can affect organ function through a variety of neurologic connections, reflexes, and possibly also the release of "chaperone" proteins and their phosphorylation. Specifically, heat shock proteins (HSP), released after fatiguing stimulation of muscles in the anterior compartment of the crus, may constitute one potential pathway that affects cytoskeletal assembly and remodeling. Circulating HSP may alter metabolism and function of distant structures, including respiratory muscles, kidney, and brain.[4]

From a myofascial perspective, trigger point pathology in the anterior tibialis muscle at ST 36 and ST 37 leads to a descending pain referral pattern that proceeds directly down the shaft of the tibia, over the anterior ankle joint, and centered substantially over and within the great toe. It is conceivable that trigger points further down could produce a similar pain referral pattern.

Trigger point provocation in the extensor digitorum longus muscle near ST 37 and ST 38 can cause pain to radiate from the mid-crus down the dorsum of the foot to digits II through IV.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular nerve (L4, L5, S1):** Supplies skin on the anterior ankle and dorsum of the foot (except for the interdigital cleft). Also supplies the fibularis (peroneus) longus and brevis muscles.
- **Lateral sural cutaneous nerve (L4, L5, S1; branch of common fibular):** Supplies skin on the lateral crus.

Clinical Relevance: The superficial fibular nerve may experience compression where it pierces the crural fascia and branches into cutaneous nerves.[5] Typically, nerve entrapment syndromes manifest as burning or "pins and needles" sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial fibular nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem.

Vessels

- **Anterior tibial artery (ATA):** Distributes blood to the anterior compartment of the leg.

Clinical Relevance: Inferolateral arteries such as the ATA are vulnerable to damage during surgical procedures such

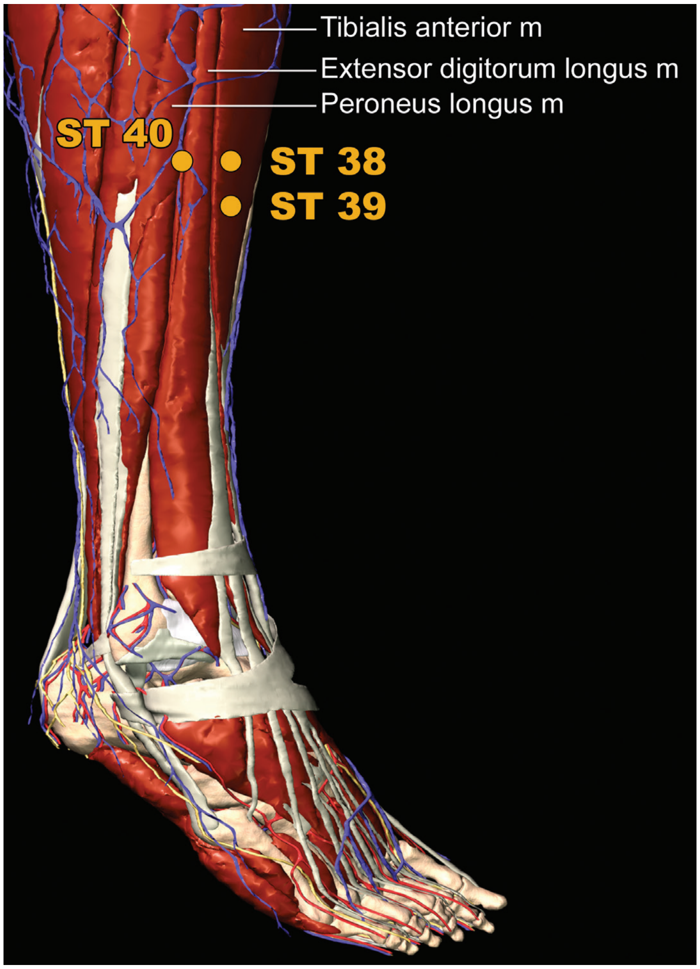

Figure 3-97. The anatomy associated with ST 38, "Tight Mouth" or "Ribbon Opening", hints at the name's origin. That is, as the extensor digitorum longus muscle ascends toward the knee, its width appears to narrow. In contrast, the tibialis anterior muscle looks like a ribbon unfurling toward the knee.

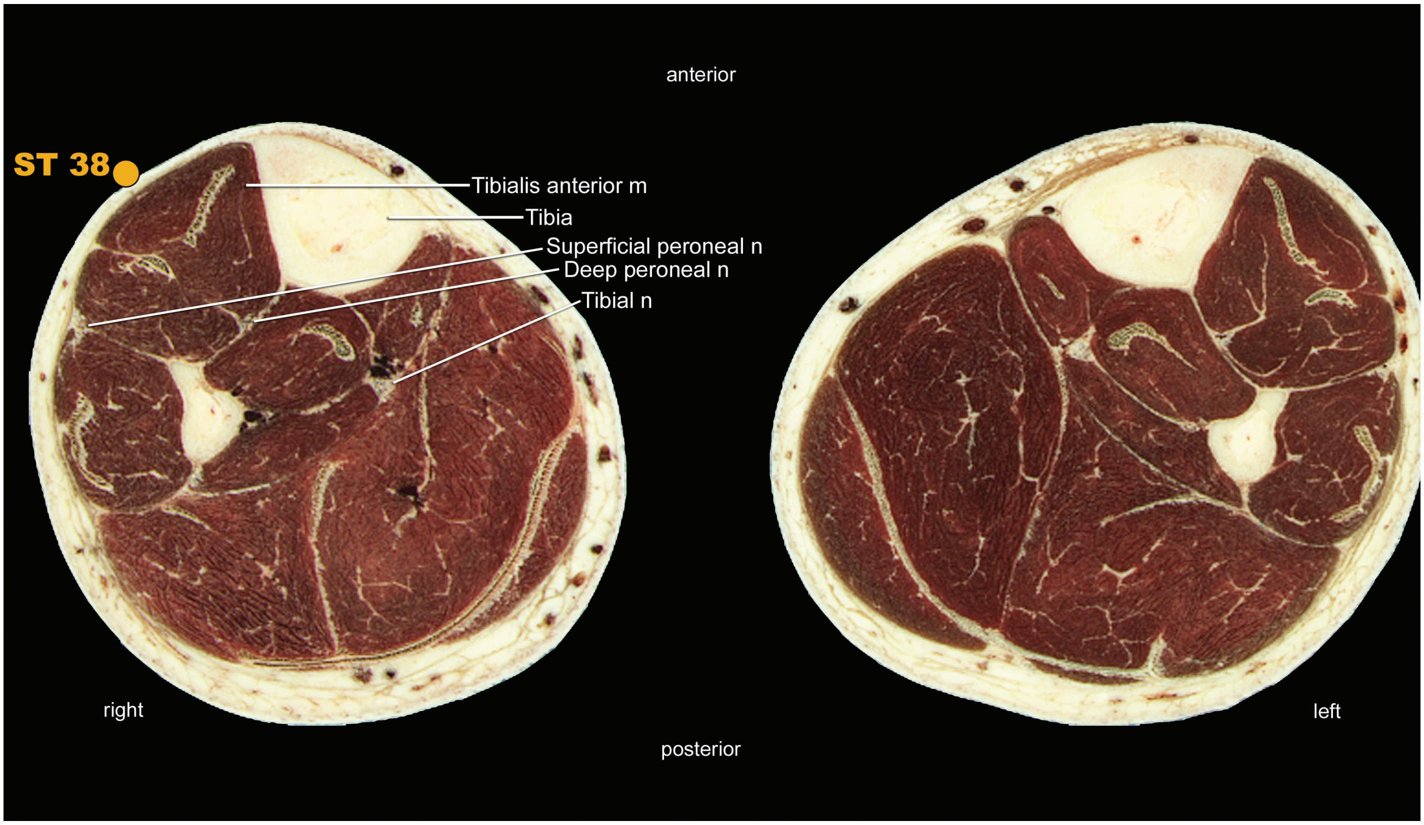

Figure 3-98. This depiction of the limb transected at ST 38 indicates the disparity in location of the superficial and deep peroneal (fibular) nerves, illustrating pictorially how the structures that they supply will differ as well.

as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[6] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Indications and Potential Point Combinations

- **Pain or paralysis in the leg:** ST 38, ST 36, Bafeng (web spaces between the toes); identify dysfunctional nerves and spinal cord segments. BL 23, BL 25, BL 27.
- **Anterolateral leg pain:** ST 38. Check for trigger points in the tibialis anterior and extensor digitorum longus muscles.

Evidence-Based Applications

- Electroacupuncture at ST 38 and GB 34 provided significantly more relief for patients with **tennis elbow** than did manual acupuncture.[1]
- Electroacupuncture at ST 36 and ST 38 potentiated the **hypotensive** effect of nitroglycerin, which helped achieve the target mean arterial pressure during microscope middle ear surgery under general anesthesia with halothane.[2]

ST 39

Xia Ju Xu “Lower Great Hollow”

On the anterolateral surface of the leg, 1 cun below ST 38 and one finger-breadth lateral to the anterior margin of the tibia.

Three cun below ST 37.

Connective Tissues

- **Interosseous membrane (IOM):** Separates the leg into an anterior and posterior compartment.

Clinical Relevance: The IOM of the leg and forearm share striking similarities, in light of the recognition that ankle and wrist injuries, respectively, simultaneously cause problems in the IOM, knee or elbow, and nerves that course between the tibia/fibula and radius/ulna.[1] Acupuncture at points such as ST 39 may improve the function and facilitate the repair of injured nerves, i.e., branches of the fibular nerve in this case.

Muscles

- **Tibialis anterior muscle:** Inverts the foot and dorsiflexes the ankle.
- **Extensor digitorum longus muscle:** Dorsiflexes the ankle and extends the lateral four pedal digits.
- **Extensor hallucis longus muscle:** Extends the big toe and dorsiflexes the ankle.

Clinical Relevance: A trigger point in the extensor hallucis longus muscle coincides with ST 39. Myofascial dysfunction in this region can cause a pain referral pattern to emanate from this site to the groove between the 1st and 2nd metatarsals, on the dorsum of the foot.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Muscles supplied include the tibialis anterior, extensor digitorum longus, and extensor hallucis longus. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular nerve (L4, L5, S1):** Supplies skin on the anterior ankle and dorsum of the foot (except for the interdigital cleft). Also supplies the fibularis (peroneus) longus and brevis muscles.
- **Lateral sural cutaneous nerve (L4, L5, S1; branch of common fibular):** Supplies skin on the lateral crus.

Clinical Relevance: The superficial fibular nerve may experience compression where it pierces the crural fascia and branches into cutaneous nerves.[2] Typically, nerve entrapment syndromes manifest as burning or “pins and needles” sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial fibular nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem. Entrapment of the deep fibular nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis, further distal on the limb.

Vessels

- **Anterior tibial artery (ATA):** Distributes blood to the anterior compartment of the leg.

Clinical Relevance: Inferolateral arteries such as the ATA are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[3] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Figure 3-99. This cross section illustrates how the muscular anatomy of the distal limb is becoming more complex, as myofascial structures narrow and become more numerous. ST 39, the “Lower Great Hollow”, resides at the distal limit of the groove created between the tibialis anterior and extensor digitorum/extensor hallucis longus muscles. ST 37, the “Upper Great Hollow”, sits at the gulley’s proximal end.

Indications and Potential Point Combinations

- **Small Intestine disorders: enteritis, abdominal pain with borborygmi, flatulence:** ST 39, ST 36, LI 4, LI 11, CV 10.
- **Leg weakness:** ST 39, ST 36, additional points pertaining to cause of weakness, including BL points related to impaired spinal cord segments.
- **Pain in the first metatarsal and first metatarsophalangeal joint:** Check for trigger points in the extensor hallucis longus muscle that refer to this region; add LR 2, LR 3.

ST 40

Feng Long “Bountiful Bulge”

On the lateral surface of the leg, 8 cun below ST 35 or 8 cun above the lateral malleolus (i.e., halfway between), two finger-breadths lateral to the anterior margin of the tibia Level with ST 38.

Muscles

- **Extensor digitorum longus muscle:** Dorsiflexes the ankle and extends the lateral four pedal digits.
- **Extensor hallucis longus muscle**: Extends the big toe and dorsiflexes the ankle.
- **Fibularis (peroneus) brevis muscle:** Weakly plantarflexes the ankle and everts the foot.

Clinical Relevance: The trigger point associated with the fibularis brevis muscle occurs in the vicinity of ST 40 The referred pain pattern issues to the lateral malleolus and along the lateral aspect of the dorsum of the foot. More distal trigger points in the fibularis brevis instead focus on the anterior angle and posterolateral heel.

Nerves

- **Lateral sural cutaneous nerve – a branch of the common fibular (peroneal) nerve:** Supplies skin on the posterolateral portion of the leg.
- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular (peroneal) nerve:** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.

Clinical Relevance: The superficial fibular nerve may experience compression where it pierces the crural fascia and branches into cutaneous nerves.[4] Typically, nerve entrapment syndromes manifest as burning or “pins and needles” sensations, loss of coordination and proprioception in the limbs, system symptoms that include dysfunctional thermoregulation, pain at night or at rest, pelvic limb or gluteal pain that worsens with movement, and/or unilateral pain or swelling in the limb. The superficial fibular nerve syndrome causes pain or sensory loss over the lateral calf and/or dorsum of the foot, accentuated with resistive dorsiflexion and eversion of the ankle. Acupuncture and related techniques applied to the site of constriction or compression should help alleviate the problem. Entrapment of the deep fibular nerve can occur where the nerve travels under the extensor retinaculum at the ankle or where it travels beneath the extensor hallucis brevis muscle.

Vessels

- **Anterior tibial artery (ATA):** Distributes blood to the anterior compartment of the leg.

Clinical Relevance: Inferolateral arteries such as the ATA are vulnerable to damage during surgical procedures such as cutting of the tibia or retracting soft tissues away from the edge of the tibia.[5] Neuromodulation may assist with circulatory benefits and, in the case of laser therapy, angiogenesis and neovascularization.

Indications and Potential Point Combinations

- **Gastrointestinal problems, especially with fluid retention or swelling:** ST 40, ST 36, SP 9, SP 6, CV 6.
- **Chest pain, asthma:** ST 40, ST 36, ST 13, BL 13, LU 1, LU 7.

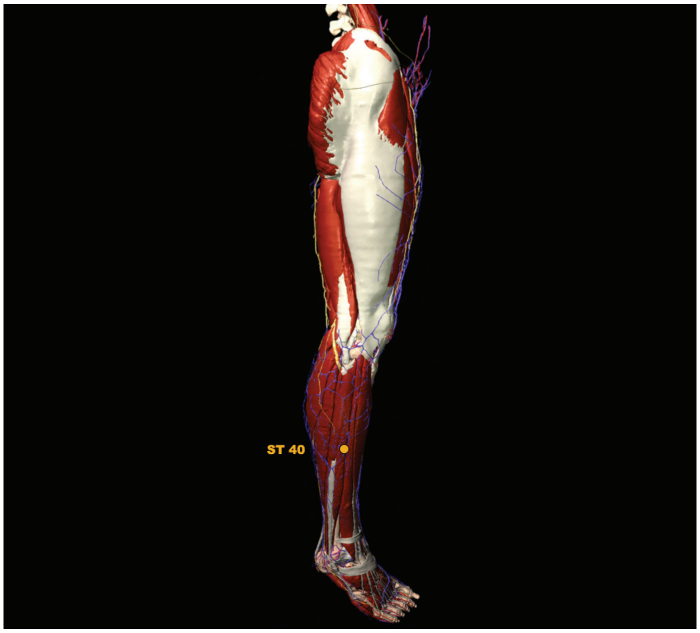

Figure 3-100. The name “Bountiful Bulge” for ST 40 describes the mound produced by the nearby gastrocnemius muscle. This contrasts sharply with the nearby “Great Hollow” described by ST 37 at one end and ST 39 at the other.

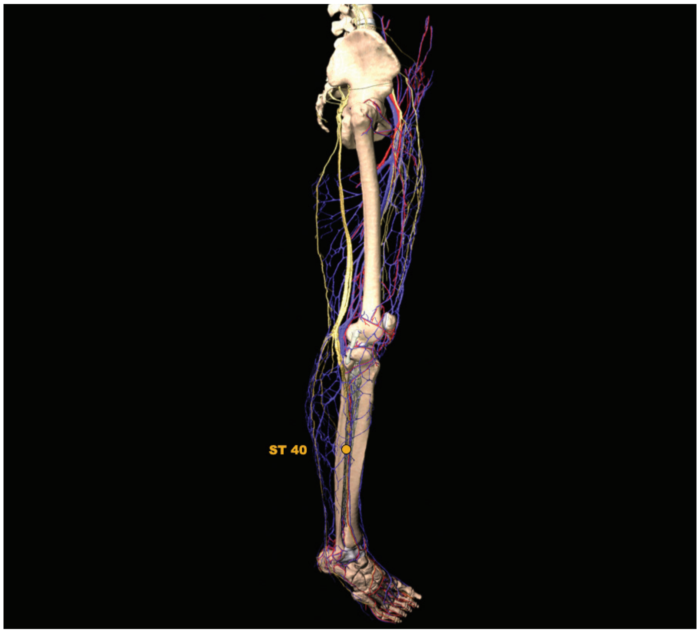

Figure 3-101. ST 40 overlies a rich neurovascular passageway, as seen in this image.

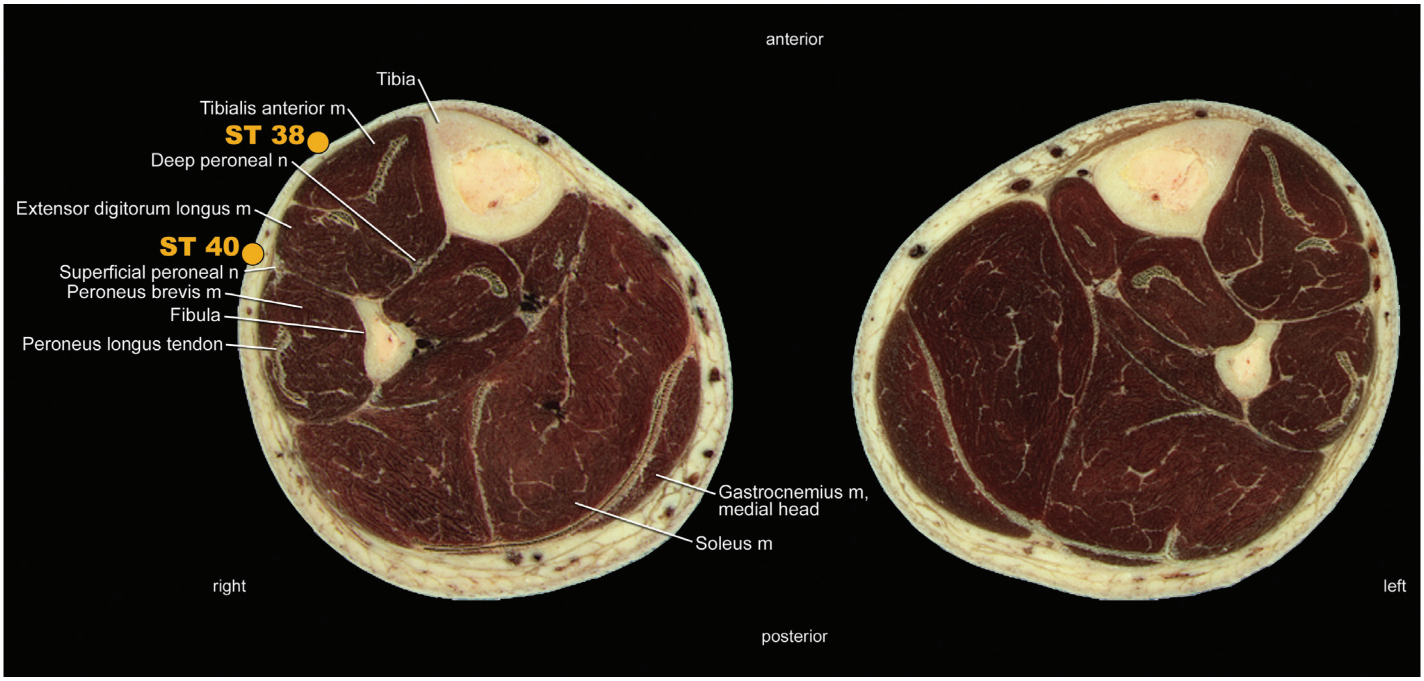

Figure 3-102. ST 40 and ST 38 lie within the same cross-section. ST 40 lives one fingerbreadth lateral to ST 38.

- **Pain or swelling of pelvic limbs:** ST 40, SP 6, SP 9, LR 8.
- **Migraine:** ST 40, LI 4, LR 3, GV 20.
- **Vertigo, dizziness:** ST 40, GB 20, BL 10, GV 20.
- **Epilepsy:** ST 40, ST 36, LR 3, LI 4, HT 7, GV 20.

Evidence-Based Applications

- Acupuncture using magnetic needles at LI 11, ST 40, and LR 3 lowered endothelin-1, a potent **vasoconstrictive peptide.**[1]
- Regarding the effects of acupuncture on canine **gastric motility** using ST 36, ST 40, ST 41, ST 42, ST 45, BL 12, or CV 12, only stimulation of ST 36 or BL 21 promoted gastric motility, whereas motility decreased with CV 12 stimulation. No significant changes in motility occurred after acupuncture at ST 40, ST 41, ST 42, or ST 45.[2]
- Acupuncture at LU 7, LI 4, LI 11, ST 40, PC 3, and PC 6 resulted in immediate improvement in forced expiratory volume in 1 second (FEV1) in **asthma patients.**[3]
- Acupuncture at ST 40, GB 20, GV 20, and LU 7, as well as dermal needle tapping at GV 14 improved symptoms in a majority of cases of patients with **vertebrobasilar ischemic vertigo,** as reported in a case series from China.[6]

ST 41

Jie Xi "Stream Divide"

On the dorsum of the foot, between the tendons of the extensor digitorum longus muscle (lateral) and the extensor hallucis longus muscle (medial), level with the prominence of the lateral malleolus.

Identify the extensor hallucis longus tendon by asking the patient to extend the big toe against resistance; this reveals the tendon of the extensor hallucis longus. Do the same for the other digits to identify the extensor digitorum longus tendon.

An alternate name for this point, Xie Dai, means "shoelaces", providing a mnemonic of sorts as to its location.

Note: Avoid needling deeply; the joint and dorsalis pedis artery sit beneath this point.

Muscles

- **Extensor hallucis longus tendon:** Extends the big toe and dorsiflexes the ankle.
- **Extensor digitorum longus tendon:** Dorsiflexes the ankle and extends the lateral four pedal digits.

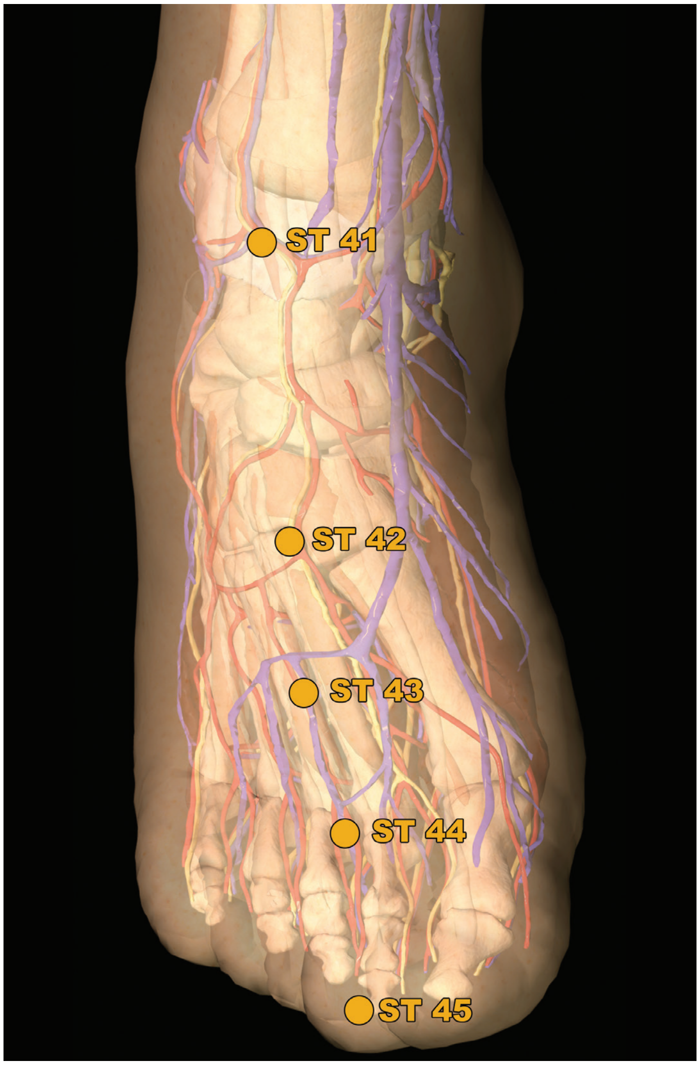

Figure 3-103. This image illustrates the proximity of ST 41 to the joint capsule.

Clinical Relevance: These two extensor tendons and accompanying neurovasculature are vulnerable to compression placed on them by the extensor retinacula of the ankle and foot. The transverse crural ligament (also known as the transverse extensor retinaculum or superior retinaculum), appears in Figure 3-104 as the uppermost of the extensor retinacula present on the dorsal ankle. This ligament binds the extensor digitorum longus, the extensor hallucis longus, the peroneus (fibularis) tertius, and tibialis anterior tendons. It is continuous with the fascia of the leg and attaches to both the tibia and fibula. Fascial restriction may compress branches of the deep fibular nerve that supply each muscle as the nerve descends along the anterior compartment. Ill-fitting shoes that compress these structures can cause pain and myofascial or neuromuscular dysfunction.[2] Instead of cutting the crural fascia with invasive approaches, acupuncture and related techniques should be tried to help reduce the pressure and relax the myofascia.

Afferent input from the skin and muscle of the ankle encode ankle joint movements.[3] Altered input from compression or stretch can disturb joint function and make the ankle more susceptible to injury. Acupuncture can modify mechanoreceptor input to correct aberrancies in neuromuscular control.[4]

Figure 3-104. At ST 41, "Ravine Divide", the tendons of the extensor hallucis longus and extensor digitorum longus tendons diverge to form the walls of a metaphorical ravine that ferries blood from the dorsalis pedis artery.

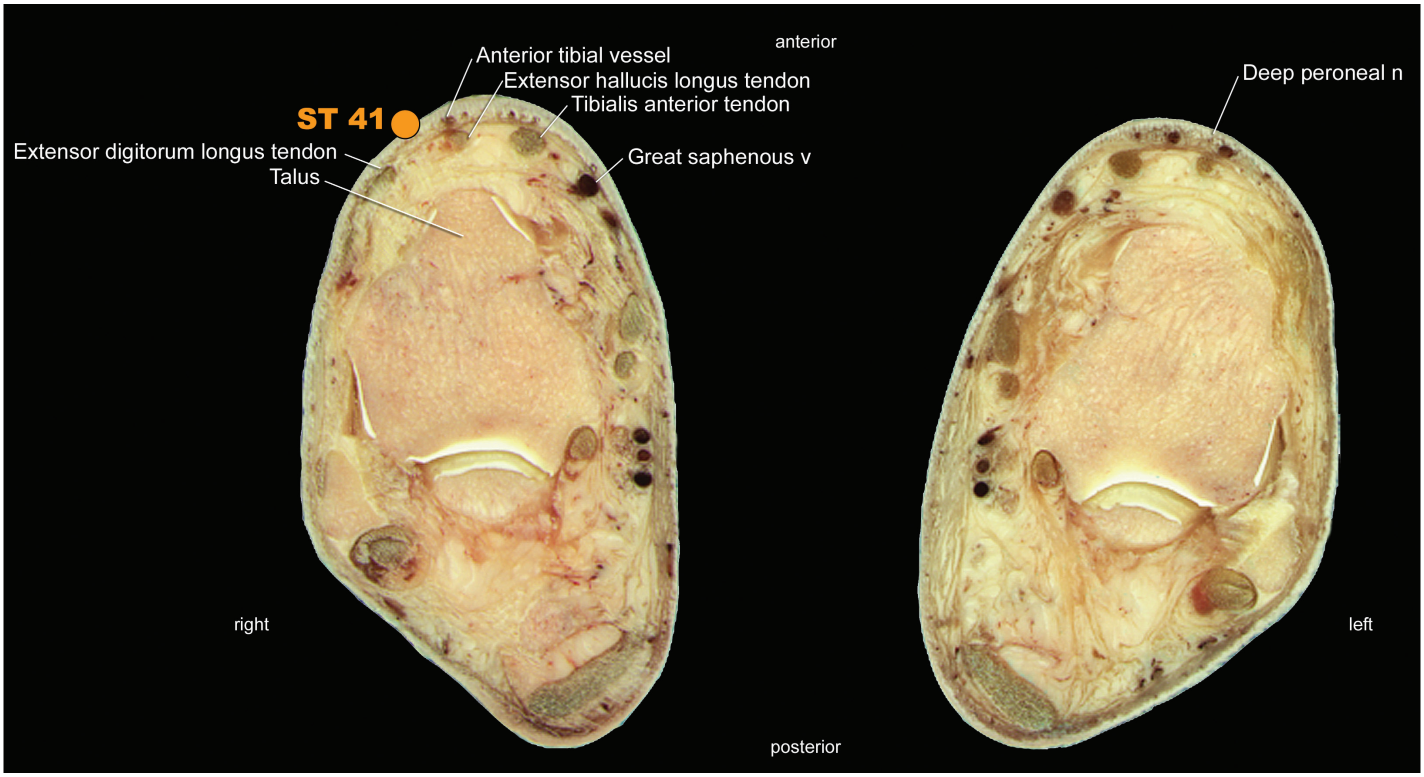

Figure 3-105. The shallow ravine in which ST 41 sits emphasizes the need to needle this point careful to avoid injuring the joint and/or nearby vessels.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular (peroneal) nerve (L4, L5, S1):** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.

Clinical Relevance: Torsional injury to the ankle can damage the common fibular nerve and its terminal branches, including the articular branch. Acupuncture in this instance may assist in improving nerve health and function.

Vessels

- **Dorsalis pedis artery:** Supplies the muscles on the dorsum of the foot. The dorsalis pedis artery pierces the first dorsal interosseous muscle and becomes the deep plantar artery, which becomes part of the plantar arterial arch.

Clinical Relevance: Avoid deep needling that might injure the dorsalis pedis artery or other vessels in this vicinity. Neuromodulation via acupuncture of the nervi vasorum may improve regional circulation.

Indications and Potential Point Combinations

- **Local inflammation, ankle pain, ankle instability:** ST 41, BL 59, BL 60, KI 3, KI 7, GB 39, GB 40, tender areas.
- **Pain or paralysis of lower extremities:** ST 41. Check for trigger-points (ST 36) in the tibialis anterior muscle which may refer pain to the region around ST 41 and the big toe (LR 2, LR 1, SP 2, SP 1). Identify other trigger points, such as extensor digitorum longus in the ST 36 region that may refer pain to GB 41-GB 44 region and the extensor hallucis longus that may send pain to the first metatarsal. For paralysis or paresis, identify dysfunctional neuroanatomic tracts and treat accordingly, not forgetting the paraspinal points addressing dysfunctional spinal cord segments. Bafeng (webspaces between toes) to encourage neural communication to digits.

Evidence-Based Applications

- Regarding the effects of acupuncture on canine gastric motility using ST 36, ST 40, ST 41, ST 42, ST 45, BL 12, or CV 12, only stimulation of ST 36 or BL 21 promoted **gastric motility**, whereas motility decreased with CV 12 stimulation. No significant changes in motility occurred after acupuncture at ST 40, ST 41, ST 42, or ST 45.[1]

ST 42

Chong Yang "Surging Yang"

On the highest part of the dorsum of the foot, approximately 1.5 cun distal to ST 41, in a depression between the tendons of the extensor hallucis longus and the extensor digitorum muscles, located over the pulsation of the dorsalis pedis artery. Can also be located on the line drawn between ST 41 and ST 43, where the dorsalis pedis artery can be palpated.

Note: References differ about the location of this point, with some placing it distal to the intermediate and lateral cuneiform bones (as shown on the CD). Another lists the location "between the first and second cuneiform bones and the scaphoid [navicular]." Because the point's name, "Surging Yang", refers to the pulse palpable at the dorsalis pedis artery, an anatomically correct location would keep it over the artery and over an accessible high point of the foot, as depicted in Figure 3-106.

Muscles

- **Extensor hallucis brevis muscle:** Part of the extensor digitorum brevis, the extensor hallucis brevis muscle extends the great toe and assists the long extensor muscles in extending the toes.
- **Extensor digitorum longus tendon:** Dorsiflexes the ankle and extends the lateral four pedal digits.

Clinical Relevance: The extensor hallucis brevis muscle may entrap the deep fibular nerve as it courses through the tight tunnel between the 1st and 2nd tarsometatarsal joints. See Figures 3-106 and 3-107 to view the relationship between the extensor hallucis brevis muscle, the aforementioned joints, and ST 42.

Nerves

- **Deep fibular (peroneal) nerve (L4, L5, S1):** Supplies motor to the anterior muscles of the leg and the dorsum of the foot. Provides sensation to the skin of the foot in the region of the first interdigital cleft. Also innervates the anterior part of the interosseous membrane while the tibial nerve innervates its posterior aspect.
- **Superficial fibular (peroneal) nerve (L4, L5, S1):** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.

Clinical Relevance: Acupuncture at ST 42 may improve the function of the deep fibular nerve in the case of entrapment or compression.

Vessels

- **Arcuate artery:** The 2nd, 3rd, and 4th metatarsal arteries arise from the arcuate artery, and divide into two dorsal digital arteries that course along the sides of adjoining toes. The metatarsal arteries are, in turn, connected to the plantar arch and plantar metatarsal arteries via the perforating arteries. The arcuate artery is not always present, but instead a dorsal arterial network consisting of the lateral tarsal artery and dorsal metatarsal arteries and proximal perforating arteries may[1] contribute to the blood supply of metatarsal arteries II through IV.

Clinical Relevance: The nervi vasorum associated with the arcuate artery may be responsible for autonomic neuromodulation derived from needling this site.

Indications and Potential Point Combinations

- **Hypertension:** ST 42, LI 11, ST 9.
- **Migraine prophylaxis:** ST 42, ST 36, LI 6, and ST 8 for headache along the LI and ST lines of the head.

Evidence-Based Applications

- **Migraine prophylaxis:**[2] Though not as effective as TH 5, GB 34, GB 40, and GB 20, ST 8, LI 6, ST 36, and ST 42 offered minor benefits for migraine prophylaxis.

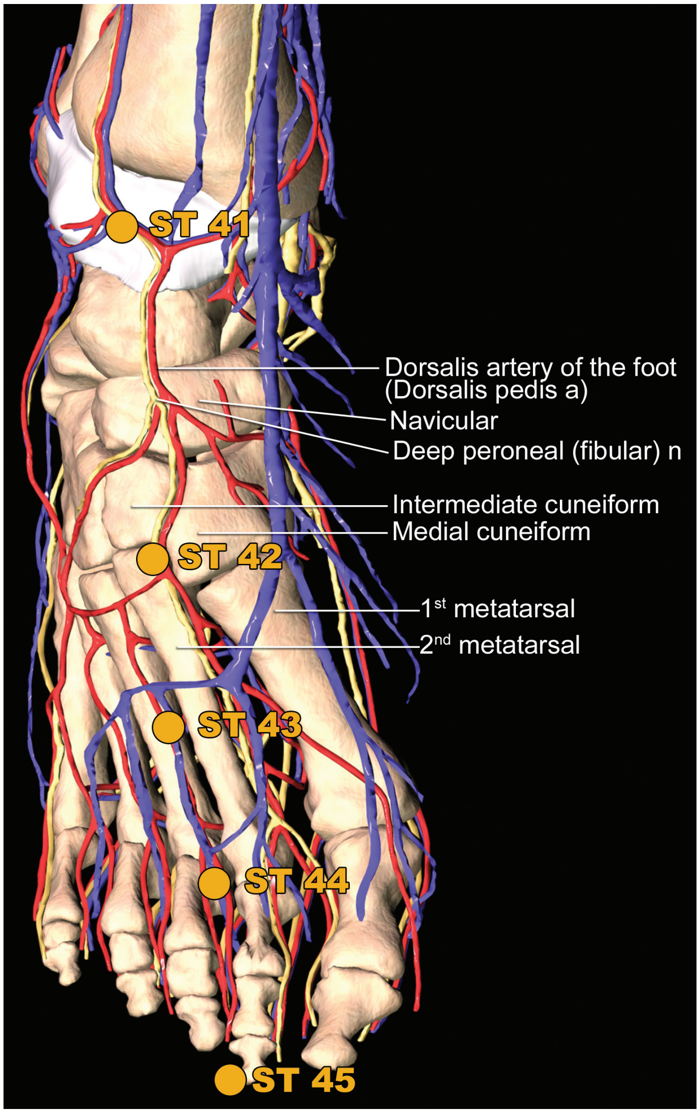

Figure 3-106. The readily palpable pulse from the prominent arterial structures at this part of the foot corresponds to the name "Surging Yang" for ST 42.

ST 43

Xian Gu "Sunken Valley"

On the dorsum of the foot, in a depression distal to the proximal juncture of the 2nd and 3rd metatarsal bones.

Muscles

- **Extensor digitorum longus tendon:** Dorsiflexes the ankle and extends the lateral four pedal digits.
- **Second dorsal interosseous muscle:** The dorsal interossei muscles of the foot abduct the 2nd through the 4th pedal digits and flex the metatarsophalangeal joints.

Clinical Relevance: Myofascial dysfunction of the foot may lead to development of trigger point pathology and discomfort when walking. Identifying the actual location of pain and the trigger point origin of referred pain initiates the process of releasing tense musculature and reducing the discomfort and pathology of nerve entrapment.

The interosseous muscles of the foot establish its architecture.[1] They provide for fine motor manipulation under normal circumstances.

Nerves

- **Superficial fibular (peroneal) nerve:** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.
- **Lateral plantar nerve:** A terminal branch of the tibial nerve, the lateral plantar nerve divides into deep and superficial branches.

The superficial branch gives off two digital nerves that provide cutaneous sensation to the little toe and the lateral part of the fourth toe. Both the superficial and deep branches supply motor branches to the quadratus plantae, abductor digiti minimi, flexor digiti minimi brevis, plantar and dorsal interossei, lateral three lumbricals, and adductor hallucis muscles.

Clinical Relevance: Ligamentous laxity or myofascial dysfunction in the foot may lead to nerve irritation. If this occurs between the 2nd and 3rd metatarsal bones, acupuncture stimulation of ST 43 may aid in its resolution.

The lateral plantar nerve may suffer entrapments at several locations from where it branches off of the tibial nerve to its myriad destinations. Relevant to ST 43, the lateral plantar nerve assists its counterpart, the medial plantar nerve, in supplying the interdigital nerves by means of their terminal branches. Morton's neuroma can afflict the plantar interdigital nerves (usually between metatarsals III and IV, however), including the one supplying the region distal to ST 43. Not a true neuroma, this pathology consists of a fibrotic nodule that forms at the site, associated with varying amounts of demyelination of the involved nerve. This perineural fibrosis occurs ordinarily where the interdigital nerve sits between the heads of the adjacent metatarsal bone. Thus, ST 43 is somewhat proximal to the usual location of a Morton's neuroma, but this site provides needling access to the axon proximal to the pathology.[2]

Vessels

- **Dorsal venous arch of the foot:** Formed by the dorsal digital veins which are continuous with the dorsal metatarsal veins in the subcutaneous tissue on the dorsum of the foot. The dorsal and plantar venous arches communicate. Veins leaving the dorsal venous arch converge to form the great saphenous vein on the medial aspect and the small saphenous vein on the lateral aspect.
- **Second dorsal metatarsal artery:** Divides into two dorsal digital arteries for the adjoining sides of the 2nd and 3rd toes.

Clinical Relevance: Dorsal interosseous muscles receive arterial blood via segmental branches off of their respective dorsal metatarsal arteries. The dorsal metatarsal arteries originate from the dorsalis pedis artery and connect with the vascular network on the plantar foot through a proximal and dorsal perforating artery. Microangiopathy or other vascular failures in patients such as diabetic individuals can compromise circulation and limit collateral vessel support, should one channel become obstructed or damaged.[3]

Indications and Potential Point Combinations

- **Disorders stemming from sympathetic nervous system arousal:** agitation, insomnia, nightmares: ST 43, ST 36, LR 2, HT 7.

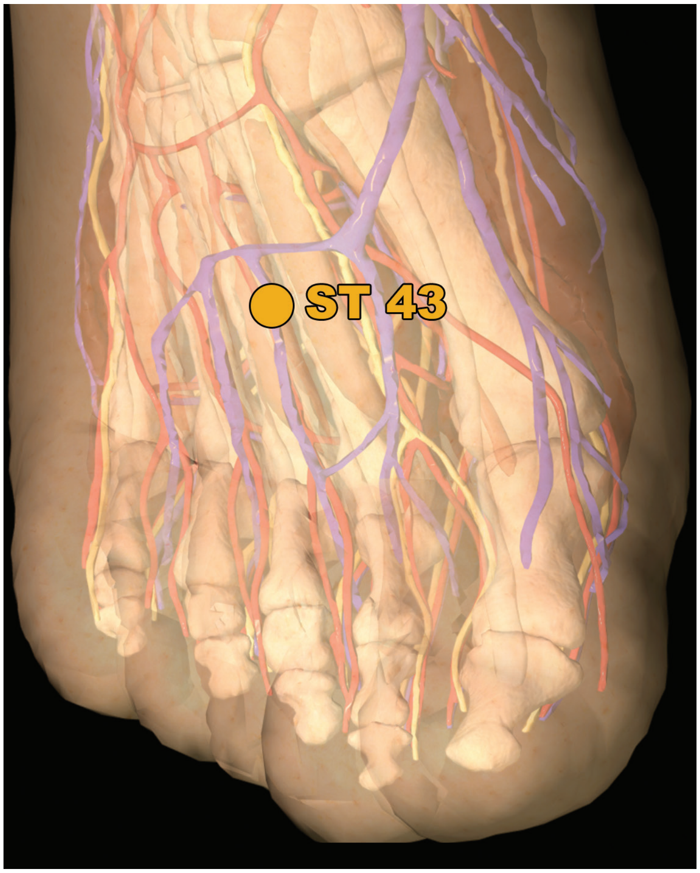

Figure 3-108. The historical association of acupuncture points to blood vessels surfaces in the names of these distal ST line points. That is, "Ravine Divide" (ST 41) leads to "Surging Yang" (ST 42), which then descends into the "Sunken Valley" at ST 43.

ST 44

Nei Ting "Inner Courtyard"

On the dorsum of the foot, distal to the 2nd and 3rd metatarsophalangeal joints, half cun proximal to the web margin.

Muscles

- **Extensor digitorum longus tendons for the 2nd and 3rd toes:** Dorsiflexes the ankle and extends the lateral four pedal digits.
- **Extensor digitorum brevis tendons for the 2nd and 3rd toes:** Extends the 2nd through 4th digits at the metatarsophalangeal joint and assists the long extensors in extending the toes.

Clinical Relevance: Acupuncture and related techniques at sites such as ST 44, or to similar sites near the other web spaces of the foot (i.e., the Bafeng points), may help stimulate recovery of neuromuscular function in cases of central nervous system damage and peripheral neuropathy.[5]

Nerves

- **Superficial fibular (peroneal) nerve:** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.

Clinical Relevance: Nerve stimulation via acupuncture and related techniques at ST 44 and its partner points near neighboring web spaces may aid in the restoration of sensation and motor control to the distal pelvic limb.

Vessels

- **Branch site of the 2nd dorsal metatarsal artery:** Two dorsal digital arteries supply the adjoining sides of the 2nd and 3rd toes.

Clinical Relevance: The rich vascularization of ST 44 heightens the ability of stimulation at this site to induce wide-ranging autonomic neuromodulation and hemodynamic shifts through the nervi vasorum of these small arteries.

Indications and Potential Point Combinations

- **Sympathetic arousal, inflammatory disorders, especially of theface:** toothache, gingivitis, oral lesions, pharyngitis, tonsillitis: ST 44, ST 36, LI 4, LU 7, CV 22.
- **Fever:** ST 44, GV 20, GV 24.5 (Yintang).

Evidence-Based Applications

- Electroacupuncture at ST 36 and ST 44 affected monoamine (serotonin, dopamine, and norepinephrine) levels in the corpus striatum of obese rats and increased ATPase activity in the striatum.[1] Striatal dopamine pathways may be influential in **pathological overeating and obesity.**[2]
- Electroacupuncture at ST 36 and ST 44 increased the frequency of spontaneous discharges of neurons in the ventromedial nucleus of the hypothalamus (VMH) in **obese** rats. It also increased the levels of tyrosine, dopamine, tryptamine, while lowering serotonin levels. This suggested that acupuncture may be beneficial for **weight reduction** by influencing the satiety center – the VMH.[3]
- Electroacupuncture at the Sanjiao (Hungry) and Shen Men (Stomach) ear points as well as body points LI 4, LI 11, ST 25, ST 36, ST 44, and LR 3 may have **lowered serum total cholesterol, triglyceride, and LDL cholesterol levels** by increasing serum beta endorphin levels.[4]

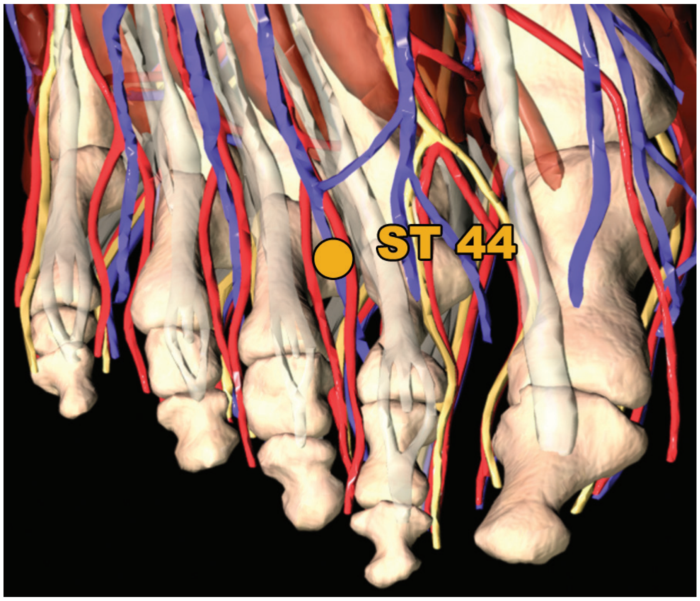

Figure 3-110. This "Inner Court", ST 44, houses a multitude of vessels, i.e., the dorsal digital arteries and veins. Although the nerves are not visible in this depiction, neurologic connections between points such as ST 44 and the face may be mediated by tracts in the spinal cord and brain stem that link caudal spinal cord segments to the spinal trigeminal tract nucleus as well as sites in the brain and brainstem. [Shankland WE. The trigeminal nerve. Part I: an overview. Journal of Craniomandibular Practice. 2000;18(4):238-248.] This helps to explain why ST 44 often appears in point formulae for pain and inflammation in the face, nose, mouth, and sinuses; i.e., areas supplied by the trigeminal nerve.

Figure 3-111. Note the vessels present in the superficial fascia below ST 44. These vascular channels contain abundant sympathetic nerve fibers that readily impact the autonomic nervous system. The Chinese described vasoregulation and autonomic neuromodulation through metaphors such as “releasing Heat” and “calming the Mind”.

ST 45

Li Dui "Strict Exchange", "Severe Mouth", "Change of Course" or "Running Point"

At the lateral nail angle of the 2nd toe.

Nerves

- **Superficial fibular (peroneal) nerve:** Innervates the skin on the distal third on the anterior leg and on the dorsum of the foot. Also supplies the fibularis (peroneus) longus and brevis muscles.

Clinical Relevance: The abundant supply of sensory nerve fibers at the ting points of the digits provide ample opportunities to neuromodulate and improve nerve function in cases of sensory or motor compromise.

Vessels

- **Dorsal digital artery for the 2nd toe:** Supplies the toe.

Clinical Relevance: The characteristics of ting points that tend to produce strong hemodynamic shifts occur as a result of the ever-narrowing arterioles that then switch direction and transform into venules. Despite their small size, these vessels are endowed with ample nervi vasorum that make ting points capable of inducing profound autonomic shifts.

Indications and Potential Point Combinations

- **Severe toothache, tonsillitis, other orofacial pain:** ST 45, LI 4, ST 5.

Evidence-Based Applications

- Acupuncture at ST 45, BL 58, ST 40, ST 36, KI 7, SP 6, LU 9, LI 4, LU 11, CV 17, LI 1, SP 1, HT 9, SI 1, BL 67, PC 9, TH 1, GB 44, LR 1, and KI 1, as well as moxa at GV 14, resulted in rapid improvement in a 13 month baby suffering from **staphylococcal skin infection** after a poor 50 day response to antibiotics.[1]

References

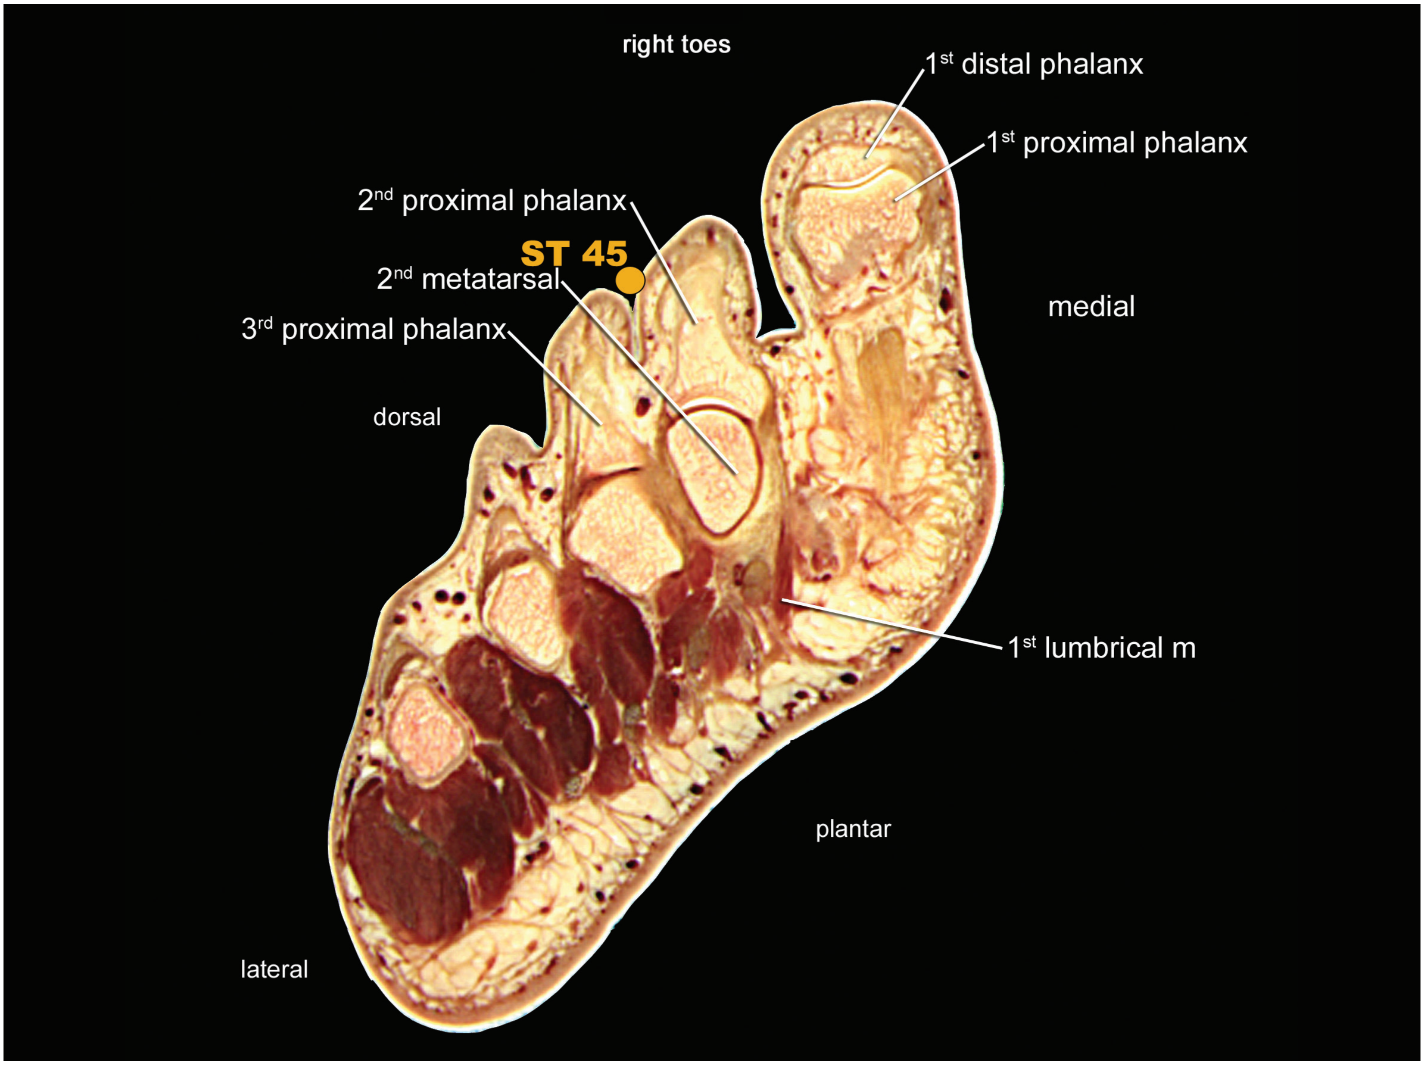

Figure 3-112. ST 45 has several names. "Severe Mouth" connotes its capacity to treat afflictions on the face and mouth. "Change of Course" implies the shift in direction taken by the blood supply. "Running Point" suggests its involvement in the push-off phase of a running foot.

Channel 4:: The Spleen (SP)

The Spleen channel begins on the medial aspect of the great toe. It ascends the medial pelvic limb, crosses the anteromedial groin, and continues toward the axilla by way of the linea semilunaris on the abdomen and along the groove lateral to the breast upon the thorax. After reaching most superior point (SP 20), the SP channel dives off its peak to the lateral ribcage, ending on the midaxillary line at SP 21.

SP 7
SP 6
SP 5
SP 4
SP 3
SP 1
SP 2

The most salient function of the SP channel concerns venous drainage. This becomes apparent when comparing the courses of the major venous pathways of the pelvic limb to the trajectory of the SP channel. Specifically, the great saphenous vein parallels the SP pathway most closely, overlapping as well with the network of interlacing lymphatics on the medial surface of the lower extremity.

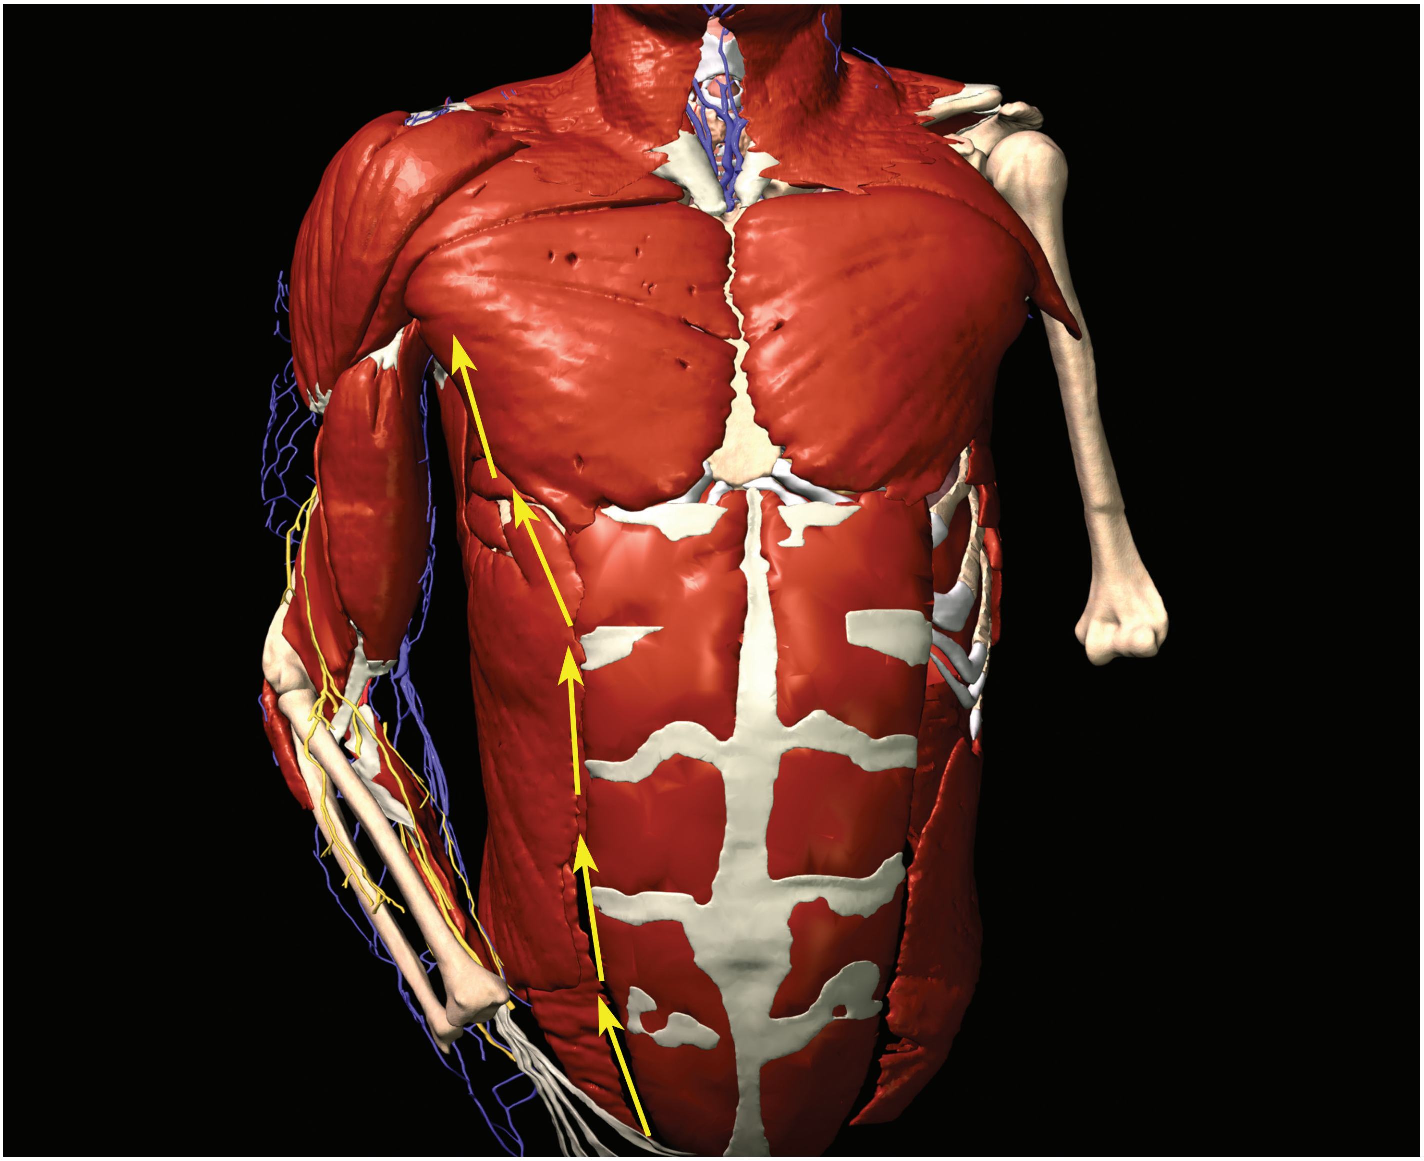
SP 7
SP 6
SP 5
SP 4
SP 3
SP 1
SP 2

From a neuroanatomic standpoint, the SP line follows the femoral nerve and its terminal cutaneous branch, the saphenous nerve.



The yellow arrows in this figure show the SP channel course across the anterior abdomen and thorax. This pathway follows one of three collateral routes for abdominopelvic venous return in the event of inferior vena caval obstruction or ligation.

That is, if blood from the lower abdomen and pelvis finds an impasse at the IVC, it can still return to the heart by way of these valveless venous channels on the body surface.

The three collateral routes correspond roughly to the acupuncture channels ST, SP, and Governor Vessel (GV). The truncal ST channel associates with the anastomosing inferior and superior epigastric veins that eventually enter the internal thoracic veins and drain into the superior vena cava.

The second pathway overlaps the SP line and makes use of the superficial epigastric or the superficial circumflex iliac veins. Ordinarily, these would empty into the great saphenous vein in the groin, but if pushed they will take advantage of a subcutaneous collateral pathway involving the thoracoepigastric vein. This takes the venous blood into the axillary vein by tributaries such as the lateral thoracic vein, lateral to the breast beneath the SP pathway.

The third collateral route involves the interlacing vessels along the GV channel that include the epidural venous plexus, lumbar veins, and the azygos network along the back.

SP 1

Yin Bai “Hidden White”

On the medial side of the base of the nail of the great toe, the width of a Chinese leek leaf from the corner of the nail (approximately 0.1 cun).

Nerves

- **Superficial peroneal nerve:** Supplies the skin on the medial great toe via dorsal digital branches.
- **Proper plantar digital branches of the medial plantar nerve:** Supplies the dorsal surface of the distal tips of the toes (including the nail bed region). This sensory branch arises from the medial plantar nerve and provides sensation to the medial aspect of the great toe.[4]

Clinical Relevance: The superficial location of the medial plantar proper digital nerve makes it vulnerable to chronic compression that often leads to neuropathy. Ill-fitting shoes or a space-occupying lesion within the toe such as a ganglion cyst can also lead to neuropathic compression. Acupuncture or related neuromodulatory techniques applied to SP 1, SP 2, and SP 3 may aid in restoring normal nerve function and reducing pain in conjunction with addressing the cause of compression.

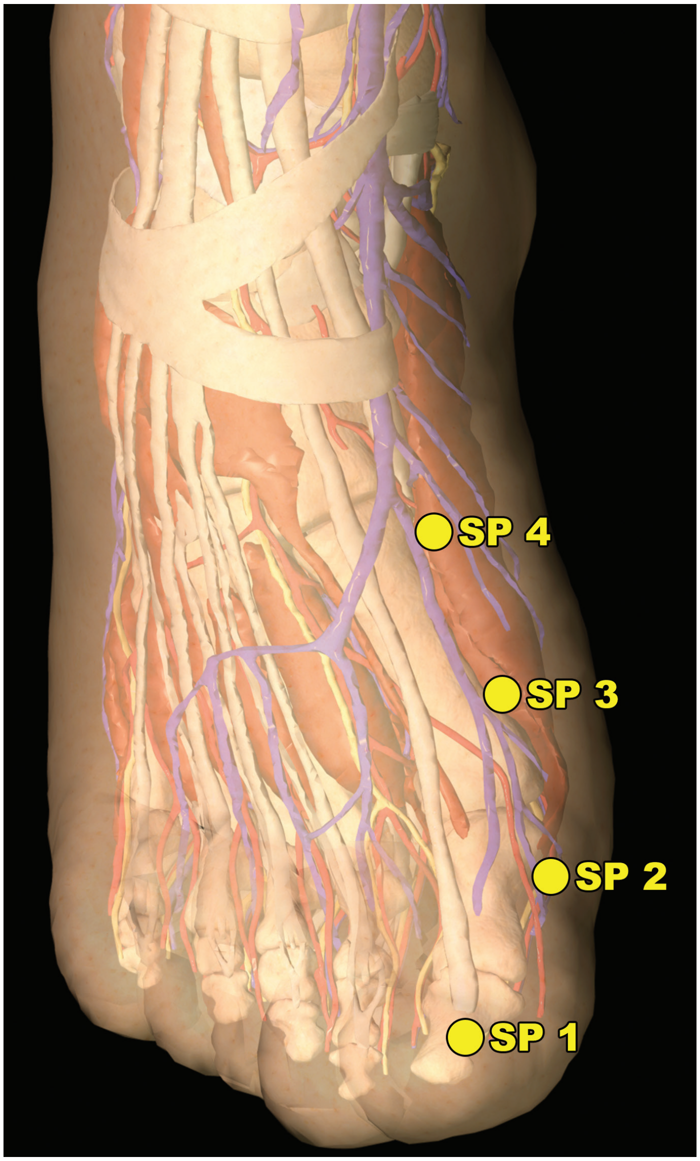


Figure 4-1. SP 1, “Hidden White”, bespeaks the lighter appearance of the skin at this site, along with the fact that it sits alongside the dark-light (dorsal-planar) junction of the medial aspect of the big toe.

Vessels

- **Proper plantar digital artery and vein:** Supply and drain, respectively, the dorsum of the distal phalangeal segment and nail bed. The artery arises from the metatarsal artery, which in turn arises from the plantar arterial arch. The vein drains into the dorsal venous arch and subsequently into the great saphenous vein.

Clinical Relevance: The redness, swelling, and pain of gout in the great toe may respond to blood-letting and cupping of SP 1 or SP 2.[5]

Indications and Potential Point Combinations

- **Bleeding disorders: hematemesis, epistaxis, hematuria, hematochezia, menorrhagia, metrorrhagia:** SP 1, SP 10, GV 20.
- **Fever, seizures:** SP 1, LR 2, ST 36.

Evidence-Based Applications

- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of **primary Raynaud’s syndrome**, demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[1]
- A case series using needling, bleeding, and cupping to treat **erysipelas** reported “good results” using SP 10, SP 1, and “visible veins”.[2]
- Fifteen minutes of electroacupuncture stimulation applied to SP 1 and LR 1 appeared to constitute the optimal setting for treating **acute pain in the pelvic limbs.**[3]

SP 2

Da Du "Great Metropolis" or "Great Prominence"

On the medial surface of the foot, in a depression distal to the first metatarsophalangeal joint, at the dorsal/plantar skin junction. Easy to find be sliding the fingertip in a distal direction over the medial aspect of the ball of the foot.

Tendons

- **Abductor hallucis tendon:** Abducts the great toe. However, its physiologic role in hallux abduction may be less important than its contribution to proper gait mechanics. The abductor hallucis assists the posterior tibial tendon in supporting and elevating the arch of the foot.[1]

Clinical Relevance: The arch of the foot reduces forces in the joints, ligaments, and muscles of the foot. The abductor hallucis muscle demonstrates significant myoelectric activity during the late stance and toe-off phases of the gait.[2] This indicates that it may help decelerate flattening of the arch following heel strike and, in contrast, elevate the arch before toe-off. Dysfunction in the abductor hallucis muscle may compromise its ability to dynamically support the arch. Local acupuncture at myofascial trigger points in the abductor hallucis as well as its attachments (e.g., SP 2) may improve its biomechanics and mechanoreceptor input.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Medial plantar nerve (larger terminal branch of tibial nerve, L5-S3):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle. At the 1st metatarsophalangeal (MTP) joint, fibers from the medial plantar nerve form the plantar proper digital nerve to the hallux. The nerve may experience compression where it cross over the medial and plantar aspects of the MTP joint on the plantar surface of the hallux in the vicinity of SP 2 and SP 3. Tight shoes may precipitate a focal neuropathy that can become chronic. Anatomic compression may result from abnormal bony ridges (e.g., bunions) or tethers that form after repetitive trauma goes unabated, leading to proliferation and hyalination of connective tissue.

Clinical Relevance: The plantar proper digital nerve to the hallux can become compressed or entrapped, prompting the onset of perineural fibrosis, leading to "Joplin's neuroma".[3] Multiple additional pathologic changes take place when compressive or

Proximal phalanx, great toe

Figure 4-3. SP 2, "Great Metropolis" or "Great Prominence" refers to the metatarsophalangeal joint of the big toe, which can become even more prominent in cases of bunions and bursitis.

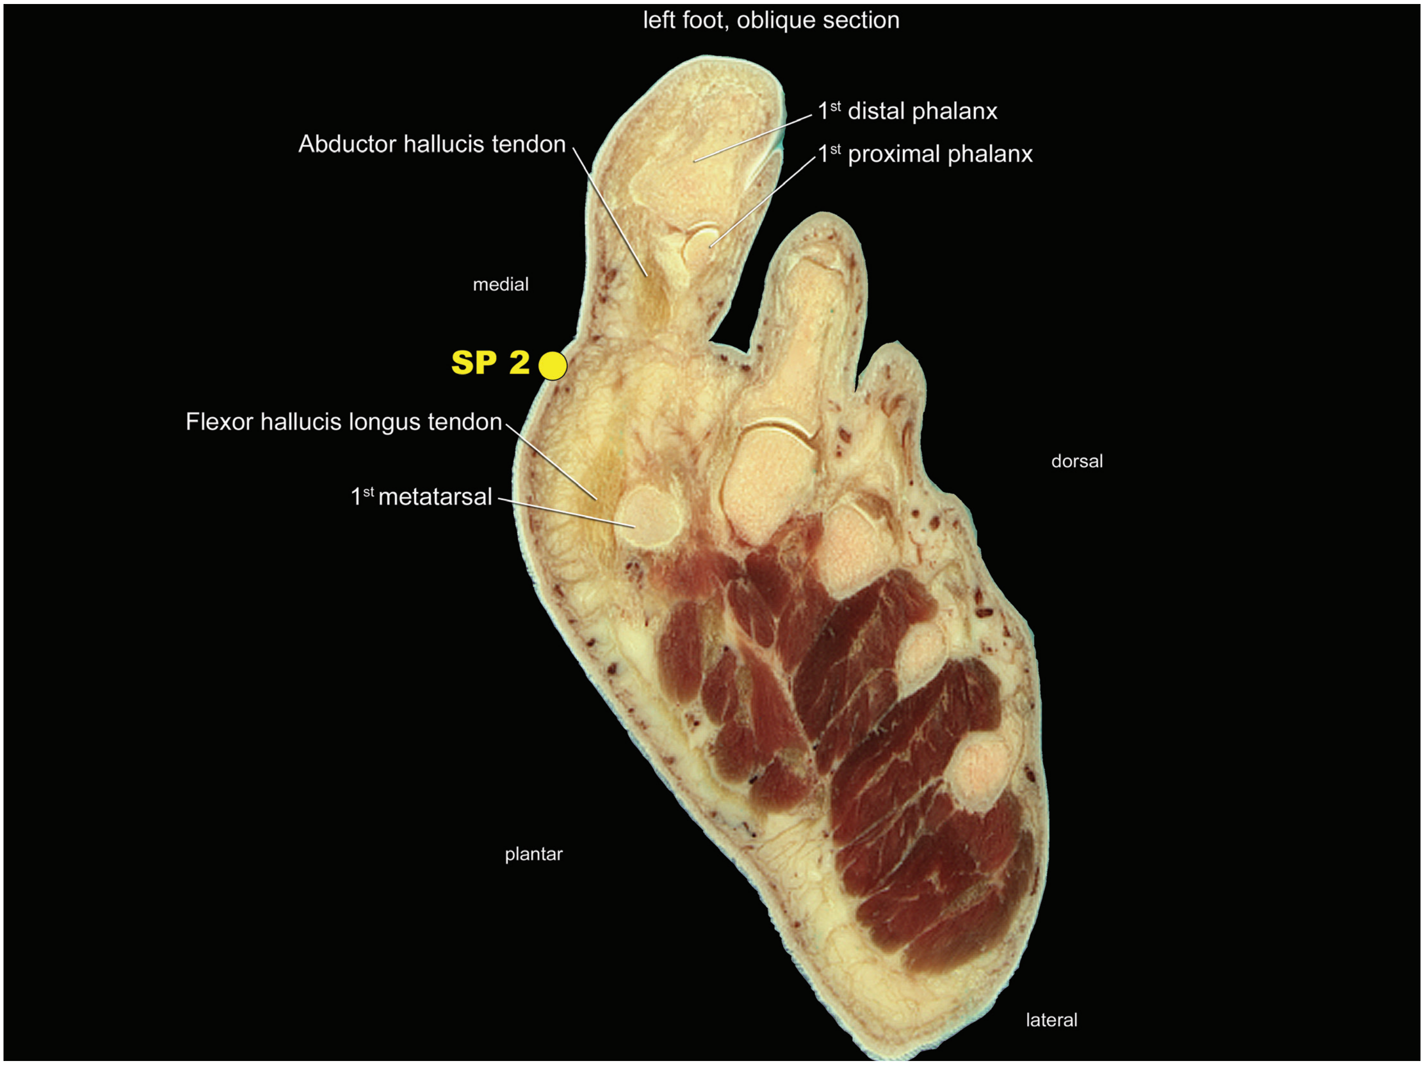

Figure 4-4. SP 2 occupies the distal valley at the 1st metatarsophalangeal joint where an abundance of superficial vessels resides, making this area vulnerable to neurovascular compression by tight-fitting shoes, biomechanical forces, and anatomical compression from bunions and connective tissue aberrancies.

entrapment neuropathy occurs. These include fibrinoid degeneration, focal demyelination, endoneural sclerosis, and edema. In addition, vessel walls fibrose, amorphous eosinophilic deposition ensues, and nerve fibers deteriorate. Pressure impacts sensory fibers more than motor fibers; patients complain of sharp or burning pain, tingling, numbness, and/or paresthesias. Allodynia causes any light touch or pressure to be experienced as pain.

Vessels

- **Medial plantar artery:** This small artery mainly supplies the muscles of the great toe. Most of the plantar digital arteries arise from the medial plantar artery. Its superficial branch provides circulation to the skin on the medial aspect of the sole. This branch gives off smaller digital branches which accompany the digital branches of the medial plantar nerve.
- **Medial marginal vein of the foot:** Joins the great saphenous vein, receiving blood from the superficial veins of the sole which form the plantar venous network.

Clinical Relevance: Entrapment or compression of the plantar proper digital nerve to the hallux (terminal branch of the medial plantar nerve) may induce or follow chronic ischemia from compressed vessels at SP 2.[4] The nerves within the vessel walls, i.e., the nervi vasorum, suffer damage when plantar neuromas develop.

Indications and Potential Point Combinations

- **Pain in or near the first metatarsophalangeal joint:** SP 2, SP 3, consider LR 2, LR 3, ST 39, extensor hallucis longus trigger point; try to determine source of pain and treat accordingly.
- **Pedal edema:** SP 2 and SP 3 (acupressure), SP 6, SP 9, CV 6.

SP 3

Tai Bai "Supreme White"

On the medial surface of the foot, in a depression proximal to the 1st metatarsophalangeal joint, at the dorsal/plantar skin junction. Easy to find by sliding the fingertip in a proximal direction over the medial bulge of the big toe.

Tendons and Muscles

- **Abductor hallucis tendon:** Abducts the great toe. However, its physiologic role in hallux abduction may be less important than its contribution to proper gait mechanics. The abductor hallucis assists the posterior tibial tendon in supporting and elevating the arch of the foot.[1]
- **Flexor hallucis brevis muscle:** Flexes the proximal phalanx of the great toe.

Clinical Relevance: The arch of the foot reduces forces in the joints, ligaments, and muscles of the foot. The abductor hallucis muscle demonstrates significant myoelectric activity during the late stance and toe-off phases of the gait.[2] This indicates that it may help decelerate flattening of the arch following heel strike and, in contrast, elevate the arch before toe-off. Dysfunction in the abductor hallucis muscle may compromise its ability to dynamically support the arch. Local acupuncture at myofascial trigger points in the abductor hallucis as well as its attachments (e.g., SP 2) may improve its biomechanics and mechanoreceptor input.

Trigger point pathology in the region of SP 3 sends referred pain distad toward the metatarsophalangeal (MTP) join, great toe, and medial second toe.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Medial plantar nerve (larger terminal branch of tibial nerve, L5-S3):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle. At the 1st MTP joint, fibers from the medial plantar nerve form the plantar proper digital nerve to the hallux. The nerve may experience compression where it cross over the medial and plantar aspects of the MTP joint on the plantar surface of the hallux in the vicinity of SP 2 and SP 3. Tight shoes may precipitate a focal neuropathy that can become chronic. Anatomic compression may result from abnormal bony ridges (e.g., bunions) or tethers that form after repetitive trauma goes unabated, leading to proliferation and hyalination of connective tissue.

Clinical Relevance: The plantar proper digital nerve to the hallux can become compressed or entrapped, prompting the onset of perineural fibrosis, leading to "Joplin's neuroma".[3] Multiple additional pathologic changes take place when compressive or entrapment neuropathy occurs. These include fibrinoid degeneration, focal demyelination, endoneural sclerosis, and edema. In addition, vessel walls fibrose, amorphous eosinophilic deposition ensues, and nerve fibers deteriorate. Pressure impacts sensory fibers more than motor fibers; patients complain of sharp or burning pain, tingling, numbness, and/or paresthesias. Allodynia causes any light touch or pressure to be experienced as pain. Patients with gout may suffer from medial and dorsal plantar hallucal entrapment if a large tophus compresses these nerves.[4]

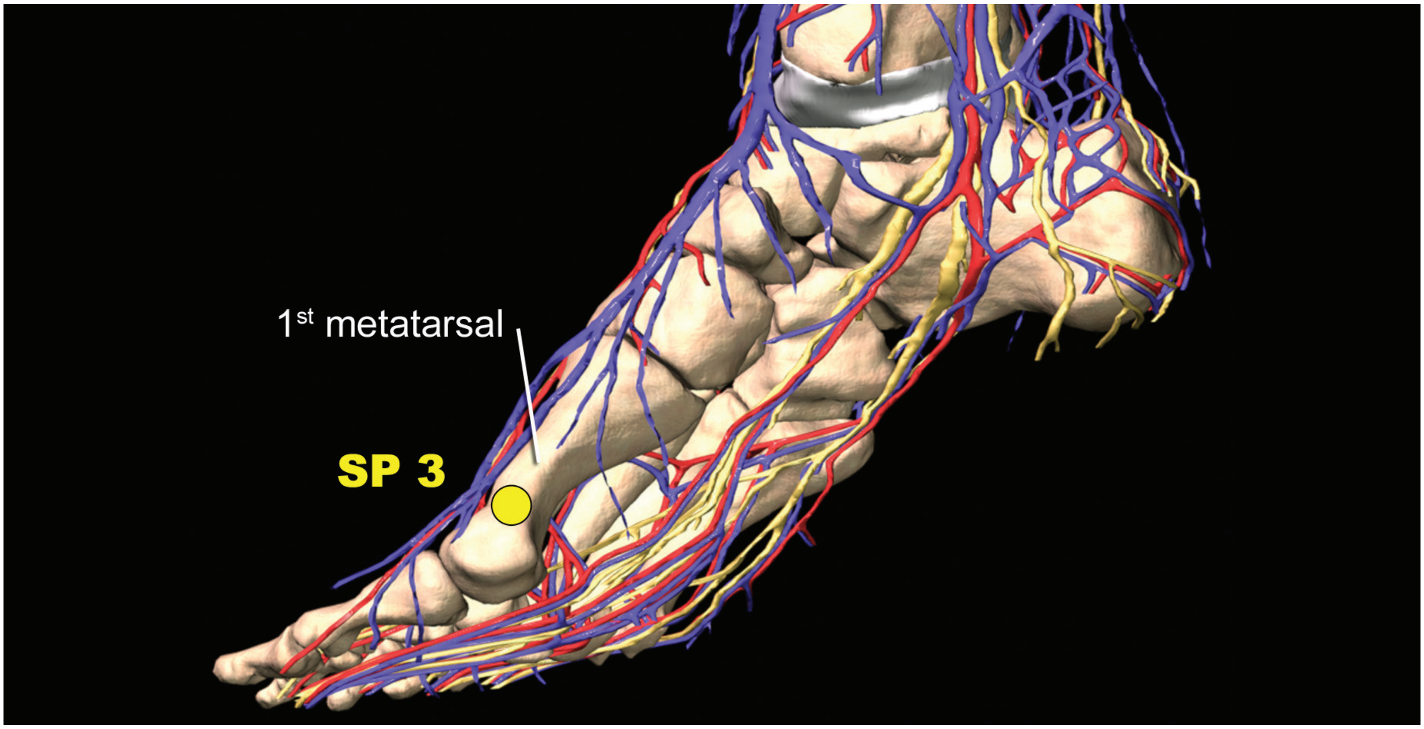

Figure 4-5. SP 3, "Supreme White" lines up with other SP channel points along the dorsal/plantar junction of the medial foot where the color changes from dark (dorsal) to light (plantar).

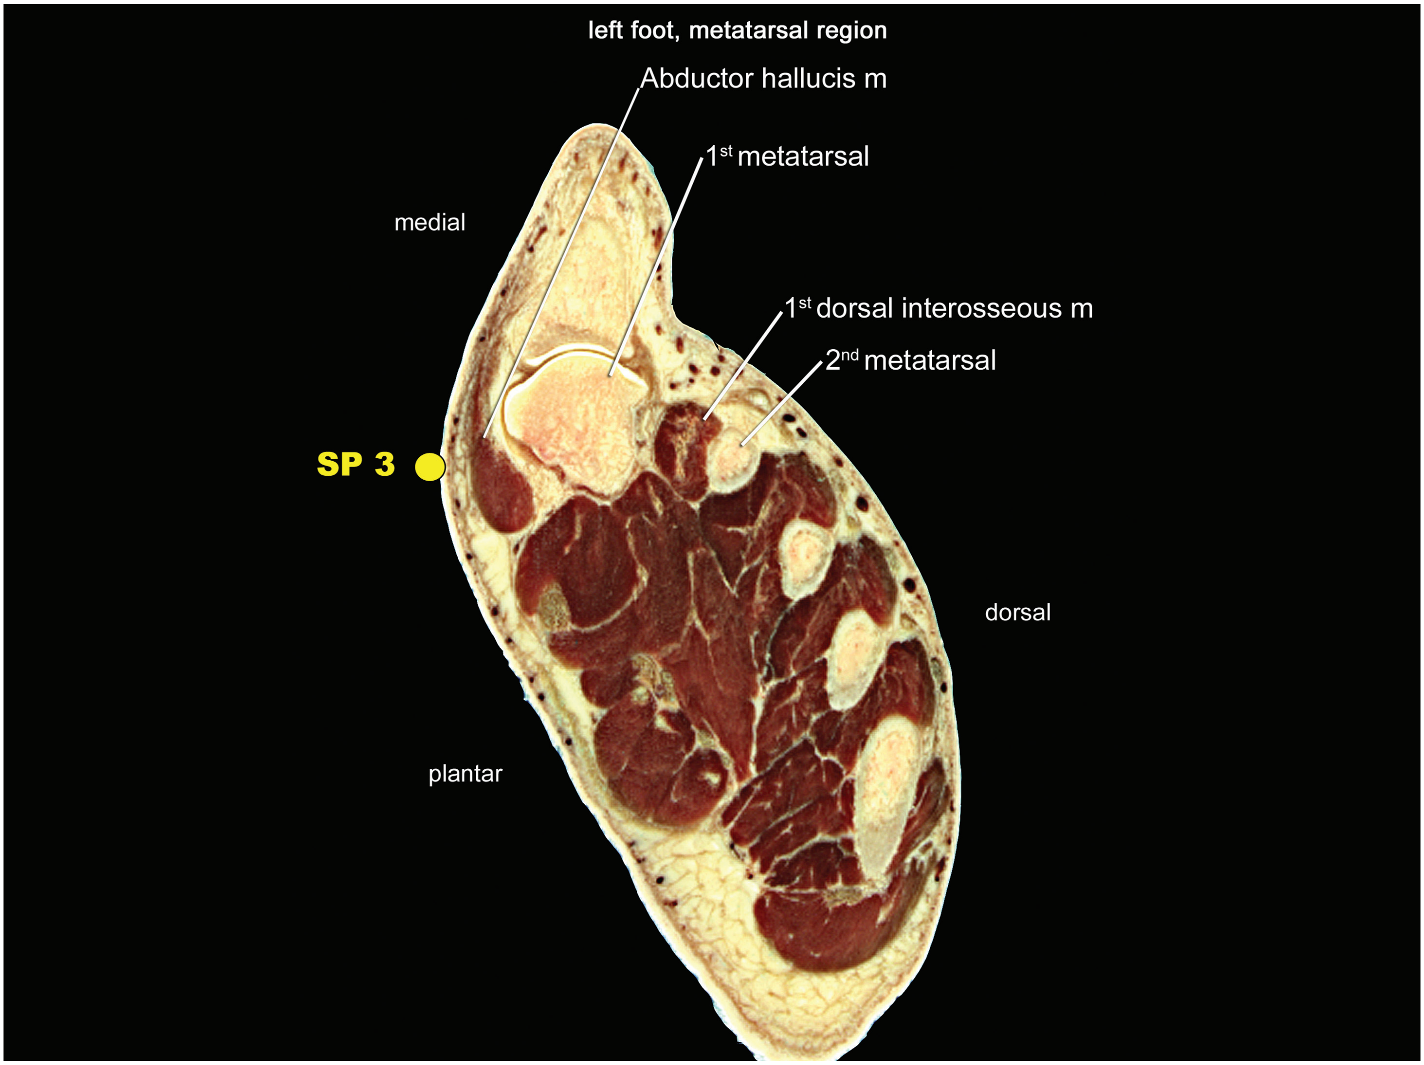

Figure 4-6. SP 3 relates to the abductor hallucis muscle.

Vessels

- **Medial plantar artery:** This small artery mainly supplies the muscles of the great toe. Most of the plantar digital arteries arise from the medial plantar artery. Its superficial branch provides circulation to the skin on the medial aspect of the sole. This branch gives off smaller digital branches which accompany the digital branches of the medial plantar nerve.
- **Medial marginal vein of the foot:** Joins the great saphenous vein, receiving blood from the superficial veins of the sole which form the plantar venous network.

Clinical Relevance: Entrapment or compression of the plantar proper digital nerve to the hallux (terminal branch of the medial plantar nerve) may induce or follow chronic ischemia from compressed vessels at SP 2.[5] The nerves within the vessel walls, i.e., the nervi vasorum, suffer damage when plantar neuromas develop.

Indications and Potential Point Combinations

- **Foot pain in the first metatarsophalangeal region:** SP 3, SP 2, SP 4, LR 2.
- **Diabetic neuropathy:** SP 3, SP 2, Bafeng, ST 36.

Evidence-Based Applications

- Shallow needling at SP 3, SP 4, ST 36, ST 25, CV 9, and CV 6 improved **diarrhea** in children, possibly by enhancing immune function and regulating motility.[6]

SP 4

Gong Sun "Grandfather Grandson"

On the medial surface of the foot, in a depression distal to the base of the 1st metatarsal bone at the dorsal/plantar skin junction. First locate SP 3, and then slide the finger in a proximal direction along the first metatarsal until it reaches a notch just distal to the base.

Tendons and Muscles

- **Abductor hallucis muscle:** Abducts the great toe. However, its physiologic role in hallux abduction may be less important than its contribution to proper gait mechanics. The abductor hallucis assists the posterior tibial tendon in supporting and elevating the arch of the foot.[5]
- **Flexor hallucis brevis muscle:** Flexes the proximal phalanx of the great toe. Accessible with deep needling of SP 4.
- **Flexor hallucis longus tendon:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It also assists the ankle in plantarflexion.
- **Tibialis anterior tendon:** Dorsiflexes and inverts the foot.

Clinical Relevance: The arch of the foot reduces forces in the joints, ligaments, and muscles of the foot. The abductor hallucis muscle demonstrates significant myoelectric activity during the late stance and toe-off phases of the gait.[6] This indicates that it may help decelerate flattening of the arch following heel strike and, in contrast, elevate the arch before toe-off. Dysfunction in the abductor hallucis muscle may compromise its ability to dynamically support the arch. Local acupuncture at myofascial trigger points in the abductor hallucis as well as its attachments (e.g., SP 2) may improve its biomechanics and mechanoreceptor input.

Trigger point pathology in the flexor hallucis brevis muscle in the vicinity of SP 4 issues referred pain to the 1st MTP joint and distad to the great toe and medial aspect of the second toe.

Flexor hallucis longus dysfunction, or FHL stenosing tenosynovitis, often accompanies or resembles flexor hallucis longus tendinitis, plantar fasciitis, and tarsal tunnel syndrome.[7]

Nerves

- **Medial plantar nerve (larger terminal branch of tibial nerve, L5-S3):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: The medial plantar nerve may become entrapped as it runs along the plantar surface of the flexor digitorum longus tendon and passes through the "Master Knot of Henry". It then branches to course along the medial and lateral aspects of the flexor hallucis longus tendon.[8] "Jogger's foot" is associated with a medial plantar nerve entrapment where it branches within the narrow space created by the abductor hallucis muscle and the anatomical crossover of the flexor hallucis longus and flexor digitorum longus tendons, the site known as the "Master Knot of Henry".[9] Jogger's foot may result from running with excessive pronation or a high medial arch. The patient experiences dysesthesia and pain along the plantar aspects of the first and second toes. Maximal tenderness occurs at the medial arch.

Vessels

- **Medial plantar artery:** This small artery mainly supplies the muscles of the great toe. Most of the plantar digital arteries arise from the medial plantar artery. Its superficial branch provides circulation to the skin on the medial aspect of the sole. This branch gives off smaller digital branches which accompany the digital branches of the medial plantar nerve.
- **Medial marginal vein of the foot:** Joins the great saphenous vein, receiving blood from the superficial veins of the sole which form the plantar venous network.

Clinical Relevance: Tension in the intrinsic foot musculature along the medial aspect can compress small nerves and vessels, exacerbating the problem.

Indications and Potential Point Combinations

- **Genitourinary problems:** SP 4, SP 6, PC 6, CV 4, CV 6, KI 3, BL 23, BL 28.
- **Digestive disorders:** vomiting, borborygmi, diarrhea, dysentery, abdominal bloating: SP 4, SP 6, ST 36, CV 12,
- **Medial foot pain:** SP 4, SP 3. Check for trigger points in the tibialis anterior (ST 36), extensor hallucis longus (GB 37, GB 38), flexor hallucis brevis (SP 3), and adductor hallucis (KI 2) muscles.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[1]
- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis**.[2]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia (OAT syndrome)**.[3]
- SP 4 and PC 6 in combination appear to work synergistically in regulating cardiac and gastric functional activities in rats with experimentally induced **acute myocardial ischemia (AMI)** by promoting recovery of normal electrical activity and through its influence on nitric oxide synthase activity in the myocardium, gastric antrum, and duodenum.[4]

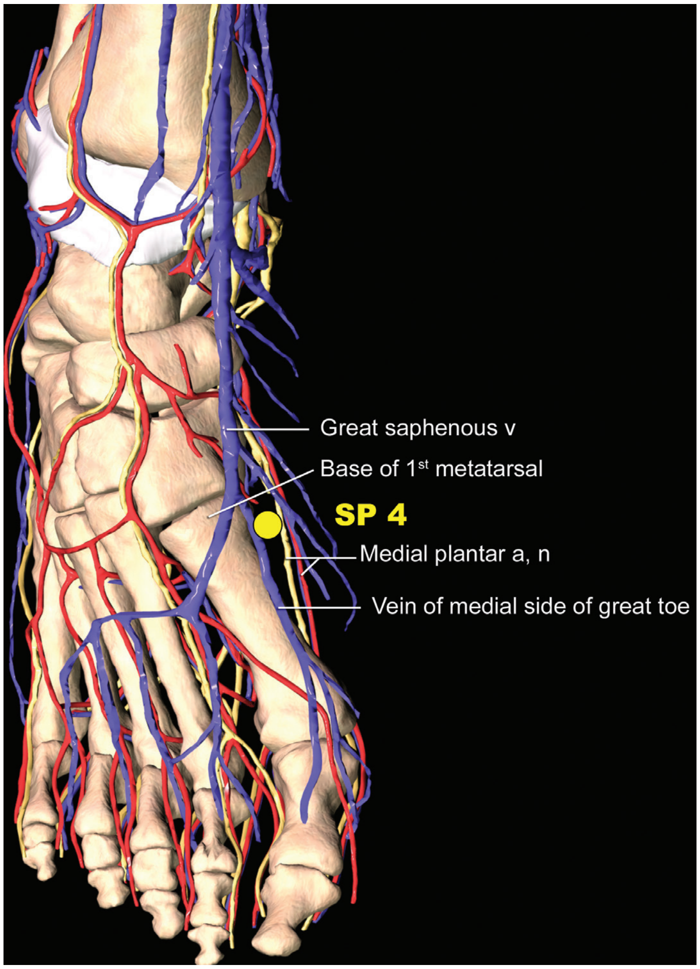

Figure 4-7. SP 4, the "Grandfather Grandson" point, is where the small veins (grandsons) of the medial foot meet the great saphenous vein (the grandfather).

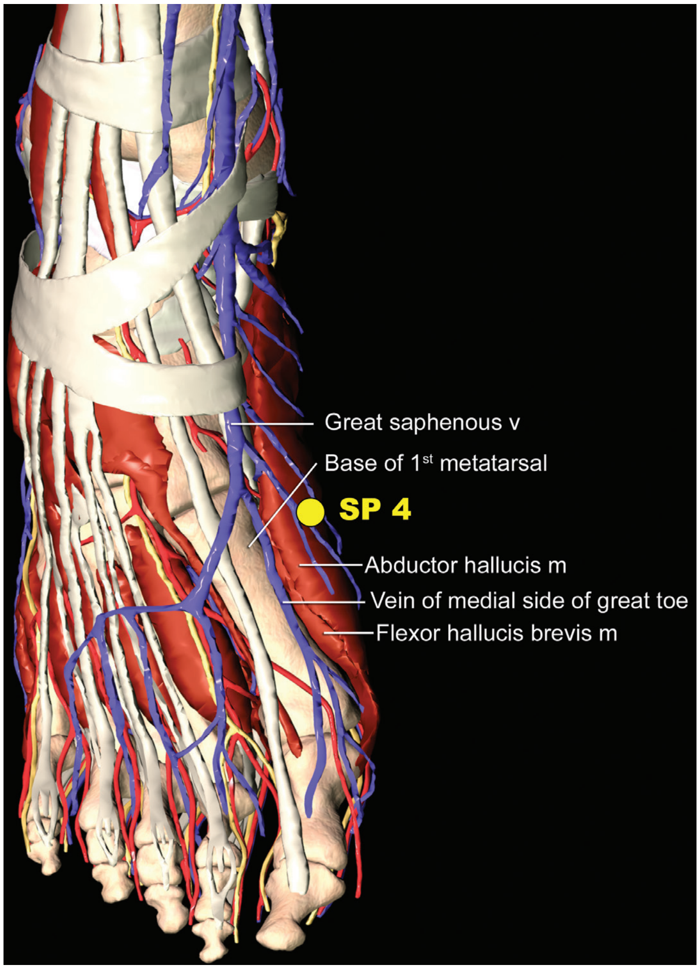

Figure 4-8. Muscles in the leg and foot display different susceptibility to form muscle cramps; the latter cramp more readily. Of the two muscles on the medial aspect of the foot along the SP channel, the abductor hallucis (AH) has a higher likelihood of cramping than the flexor hallucis brevis (FHB). (Minetto MA and Botter A. Elicitability of muscle cramps in different leg and foot muscles. Muscle Nerve, 2009.). When treating medial foot pain, carefully palpate all muscles to better isolate the source of muscle cramping.

SP 5

Shang Qiu "Shang Mound" or "Shang Hill"

On the medial surface of the foot, in the depression distal and inferior to the medial malleolus, midway between the tuberosity of the navicular bone and the prominence of the malleolus.

Note: Since the ankle joint lies deep to this point (as does the great saphenous vein), caution is warranted so as to avoid intra-articular insertion or damage to the vein.

Connective Tissues

- **Anterior tibiotalar and tibionavicular ligaments:** Four medial ligaments fan out from the tibia's medial malleolus. They attach to the talus, calcaneus, and navicular bones. These ligaments include the anterior and posterior tibiotalar, the tibionavicular, and the tibiocalcaneal ligaments. Collectively, they comprise the deltoid ligament.

Clinical Relevance: Joint stability requires fine interactions of static and dynamic components.[1] The aforementioned ligaments along with joint surface congruity limit joint translation while proprioceptive control over compressive and directional forces fall under the purview of nerves. Ligaments house mechanoreceptors, including Ruffini endings, Pacinian corpuscles, and Golgi-like endings (rare), as well as free nerve endings and various unclassifiable corpuscles. Sensory corpuscles and blood vessels occur, for the most part, close to ligamentous insertions onto bone, along with epiligamentous areas that provide support for the neurovascular bundles traveling into the ligament. Because most ligamentous disruption occurs in areas lacking neurovascular structures, proprioceptors and vessels are spared and thus can help heal a rupture ligament. Partial deafferentation of a ligament caused by damage to the sensory endings in the joint capsule and ligament may induce a functional instability in the ankle joint, leading to loss of position sense, reduced strength, delayed reaction time, and impaired control over posture. Acupuncture directed at restoring appropriate sensory input in periarticular structures at locations such as SP 5 may aid in restoring proprioceptive sensitivity to augment stabilization of the ankle joint.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: The distal saphenous nerve at the ankle may be injured during arthroscopy, fixation of distal tibia medial malleolar fractures, invasive approach to tarsal tunnel syndrome, and other surgical approaches to the ankle.[2]

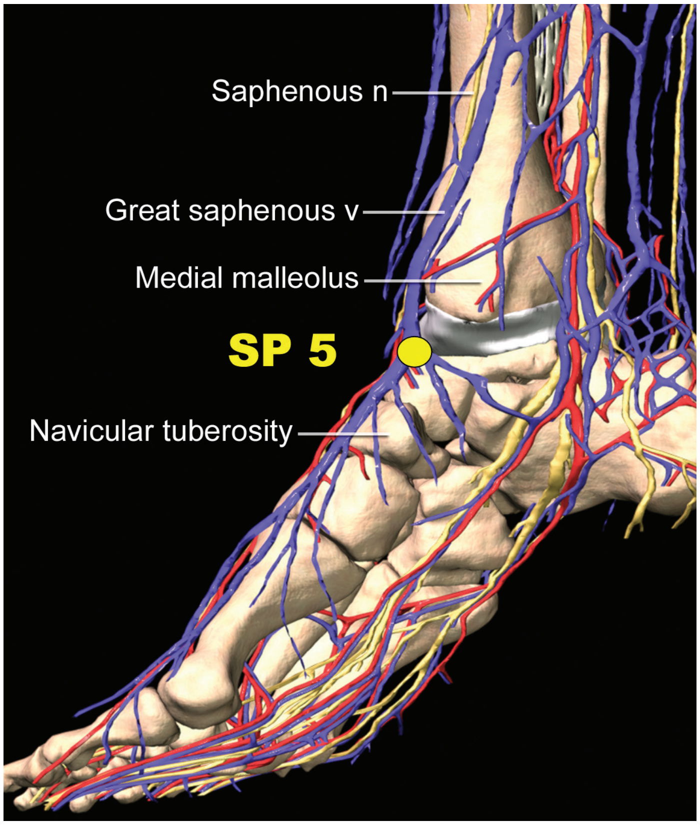

Figure 4-9. The hill in the name "Shang Hill" for SP 5 refers to the medial malleolus.

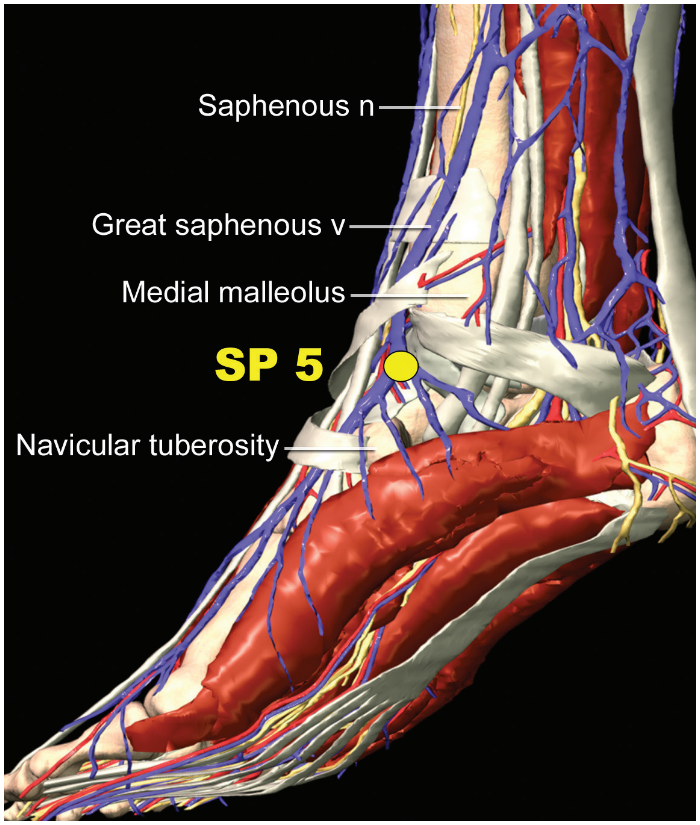

Figure 4-10. The proximity fo the ankle joint and the great saphenous vein to SP 5 anatomically justify its indications of ankle pain and foot swelling. The proximity of the ankle joint suggests caution when needling in order to avoid joint entry.

Figure 4-11. Amidst the many tendons present, SP 5 remains faithful to its venous association, shown here over the great saphenous vein.

Vessels

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch. Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein.
- **Medial tarsal artery:** Arises from the dorsalis pedis artery; supplies the medial ankle (tarsal) area.
- **Medial malleolar arterial and venous network:** Provides and drains blood to and from the medial malleolar region, respectively.

Clinical Relevance: Sympathetic fibers travel with the peripheral nerves to supply arteries and larger veins with nervi vasorum.[3]

The great saphenous vein is often targeted during procedures designed to treat varicose veins. Stripping of the great saphenous vein may lead to saphenous nerve injury.[4] Should saphenous nerve injury occur, acupuncture and related techniques may aid in the recovery of this peripheral nerve.

Indications and Potential Point Combinations

- **Local pain:** SP 5; check for trigger points in the flexor digitorum longus trigger point (LR 7 region), medial head of the gastrocnemius muscle (BL 55 region),and especially the tibialis anterior (ST 36).
- **Venous insufficiency, pain from varicosities and circulatory compromise:** SP 5, Bafeng (web spaces between the toes), SP 6, ST 36, CV 6.

SP 6

San Yin Jiao "Three Yin Intersection"

On the medial side of the leg, on the posterior border of the tibia, 3 cun proximal to the prominence of the medial malleolus.

Can stimulate labor; avoid in pregnancy until time of parturition.[22]

Muscles

- **Flexor digitorum longus muscle:** The flexor digitorum longus flexes the lateral four pedal digits and plantarflexes the ankle. It helps support the longitudinal arch of the foot.
- **Flexor hallucis longus muscle:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It also assists the ankle in plantarflexion.
- **Posterior tibialis muscle:** This muscle inverts the foot and provides ankle plantarflexion. Called the "runner's nemesis".

Clinical Relevance: Exercise produces functional sympatholysis.[23] A trigger point in the soleus at SP 6 refers pain along the proximal lower leg toward the calf but even more strongly toward the heel and plantar aspect of the mid-foot. A trigger point in the flexor hallucis longus within reach of a needle inserted into SP 6 refers strongly to the medial and plantar aspects of the big toe.

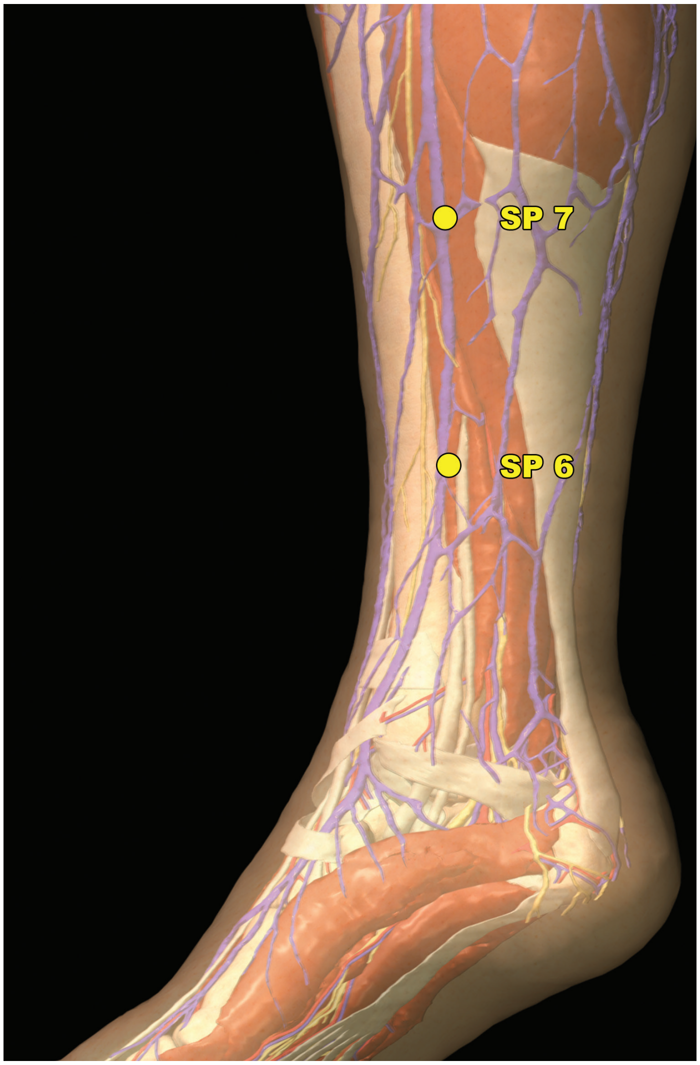

Figure 4-12. SP 6, "Three Yin Intersection", lives three cun proximal to the medial malleolus, on the Yin, or inner, side of the leg, where the SP channel intersects with the LR and KI channels.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee. At SP 6, the tibial nerve occupies the location known as the "high tarsal tunnel".[24] Nerve compression can result from myofascial restriction involving the flexor digitorum longus and flexor hallucis longus, the soleus, and tibialis posterior.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Women treated with percutaneous tibial nerve stimulation for overactive bladder syndrome may experience a transient sensory deficit in the region of SP 1, SP 2, to SP 3. Acupuncture along the SP line may aid in the recovery of sensory nerve function in the tibia.[25] The fact that sacral spinal segments contribute significantly to the fiber composition of the tibial nerve helps explain why stimulation of points such as SP 6 and KI 3 neuromodulate pelvic organ function, and why these points appears so often in needling protocols for genitourinary concerns and voiding dysfunction. In particular, segments supplying the tibial nerve as it innervates the flexor hallucis longus and flexor digitorum longus arise from S2 and S3, the most caudal segments associated with the tibial nerve.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch.

Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein. A rich, mixed, vascular network (vasa vasorum) and attendant nerve accompany the great saphenous vein from ankle to knee.[26]

- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin from the superficial veins. Because the perforating veins traverse this fascia at an oblique angle, muscular contraction and pressure within the compartment compress them. This promotes venous return to the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[27]

Indications and Potential Point Combinations

- **Immune and endocrine stimulation:** SP 6, ST 36, GV 14, LI 11, LI 4.
- **Promotes menstrual flow:** SP 6, ST 36, CV 4, BL 25.
- **Reproductive problems:** dysmenorrhea, leukorrhea, orchitis, hernia, spermatorrhea: SP 6, SP 4, PC 6, ST 29, SP 30, CV 3, CV 4.
- **Micturition disorders:** SP 6, KI 3, BL 28, BL 23.
- **Lower abdominal pain:** SP 6, ST 36, CV 6, CV 12.
- **Diarrhea and abdominal distension:** SP 6, ST 36, CV 12, BL 25.
- **Calf pain:** SP 6, palpate tibialis posterior muscle trigger point (near BL 55) for referred pain extending to the ankle and foot.

Evidence-Based Applications

- The four points LI 11, SP 10, SP 6, and ST 36 treat **urticaria.**[1]
- Acupuncture at SP 6 produced a strong vasoconstriction in the ipsilateral leg and a slight **vasoconstriction** in the contralateral leg with no change in the arms. Stimulation of ST 36 produced a superficial vasoconstriction in the skin of both legs but no change in the arms. Stimulation of PC 6 or LI 11 caused ipsilateral vasoconstriction in the arms only. This information suggests a topographical representation in the neural segments responsible for the change in sympathetic activity.[2]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[3]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with **Sjögren's syndrome.**[4]
- Acupuncture-like transcutaneous nerve stimulation at SP 6, ST 36, LI 4, and CV 24 improves whole saliva production in patients with **radiation-induced xerostomia** in head-and-neck cancer patients treated with radical radiotherapy.[5]
- Case report of improvement with acupuncture at LR 3, KI 3, SP 6, and ST 36 for **sweating associated with malignancy**, unresponsive to other measures.[6]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes.**[7]
- Electroacupuncture at CV 4, GV 20, SP 6, KI 3, and HT 7 may have afforded a modulating positive effect on **psychogenic and non-psychogenic erectile dysfunction.** It improved the quality of erection and restored sexual activity in 39% of patients.[8]
- Transcutaneous electrical nerve stimulation at SP 6 and LR 3 significantly increased the frequency and strength of **uterine contractions** in post-dates pregnant women.[9]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combi nation with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome**, thereby offering an alternative to pharmacologic induction of ovulation.[10]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction.**[11]

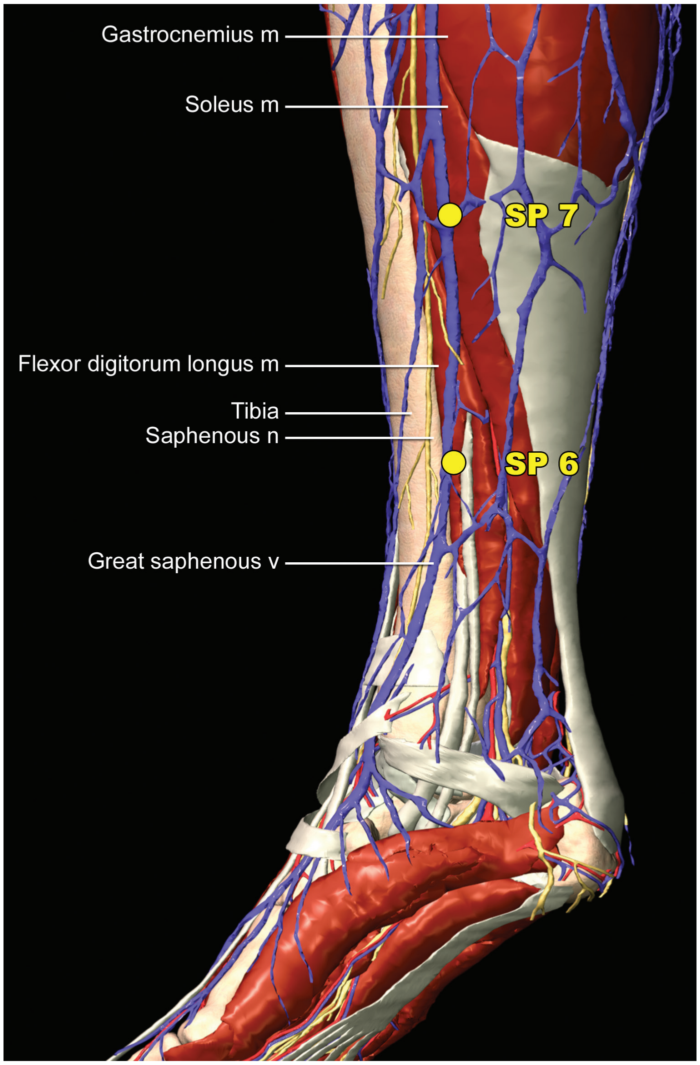

Figure 4-13. The autonomic indications for SP 6 pertain to both the sympathetic regulatory activities of the nervi vasorum associated with the greater saphenous vein and the neurologic reflexes that take place between the local innervation (tibial and saphenous nerves) and the spinal cord.

- Acupressure at SP 6 has been shown to be effective for **decreasing labor pain and shortening the length of delivery time** in women during labor.[12]
- SP 6 regulated cyclooxygenase-2 (COX-2) expression in pregnant rats, **inhibiting uterine motility.**[13]
- Acupuncture at LI 4 and SP 6 can shorten the time interval between estimated date of confinement (EDC) and actual delivery time. Helps **support cervical ripening.**[14]
- Needling GB 34, ST 36, SP 6, and BL 67 may help decrease the **need for labor induction and cesarean section.**[15]
- Acupuncture at SP 6 and LI 4 was shown to **increase cervical dilatation** without causing changes in human chorionic gonadotropin (HCG).[16]
- Acupuncture at SP 6 provided an immediate and effective means of pain and anxiety reduction in adolescent girls with **primary dysmenorrhea.**[17]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage

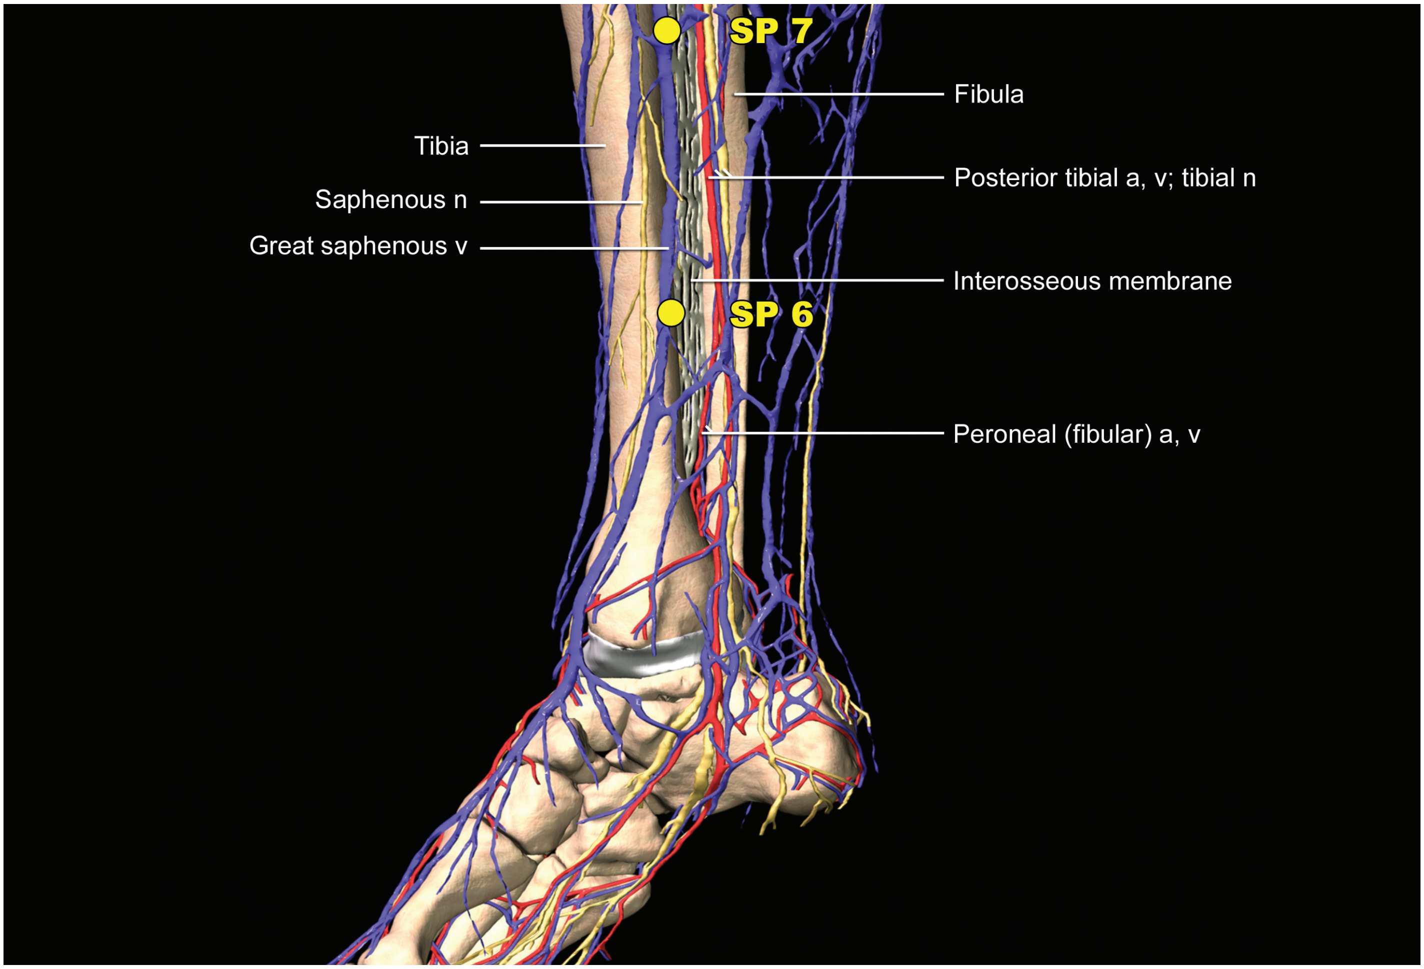

Figure 4-14. The three "Yin" channels crossing at San Yin Jiao ("Three Yin Intersection") refer to the great saphenous vein, the tibial nerve, and the saphenous nerve. These anatomical structures correspond to three acupuncture channels, to which they roughly correspond to SP, KI, and LR, respectively.

of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia (OAT syndrome).**[18]

- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[19]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in **improvement in sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[20]
- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[21]

SP 7

Lou Gu "Dripping Valley"

On the medial side of the leg, on the posterior border of the tibia, 6 cun proximal to the prominence of the medial malleolus, or 3 cun proximal to SP 6.

Muscles

- **Gastrocnemius muscle:** The gastrocnemius muscle raises the heel during ambulation. It flexes the leg at the knee, and plantarflexes the ankle if the knee is extended.
- **Soleus muscle:** Steadies the leg on the foot and plantarflexes the ankle, regardless of the position of the knee.
- **Flexor digitorum longus muscle:** The flexor digitorum longus flexes the lateral four pedal digits and plantarflexes the ankle. It helps support the longitudinal arch of the foot.
- **Flexor hallucis longus muscle:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It also assists the ankle in plantarflexion.
- **Posterior tibialis muscle:** This muscle inverts the foot and provides ankle plantarflexion.
- **Plantaris tendon:** Assists the gastrocnemius muscle in knee flexion and ankle plantarflexion.

Clinical Relevance: Trigger point pathology in the flexor digitorum longus near SP 7 refers pain down the spleen channel to the medial malleolus as well as the central plantar region of the foot. Needling into the tibialis posterior at this level may accentuate the referred pain and translate it more caudal along the gastrocnemius, to the calcaneal tendon, and over the plantar aspect of the foot.

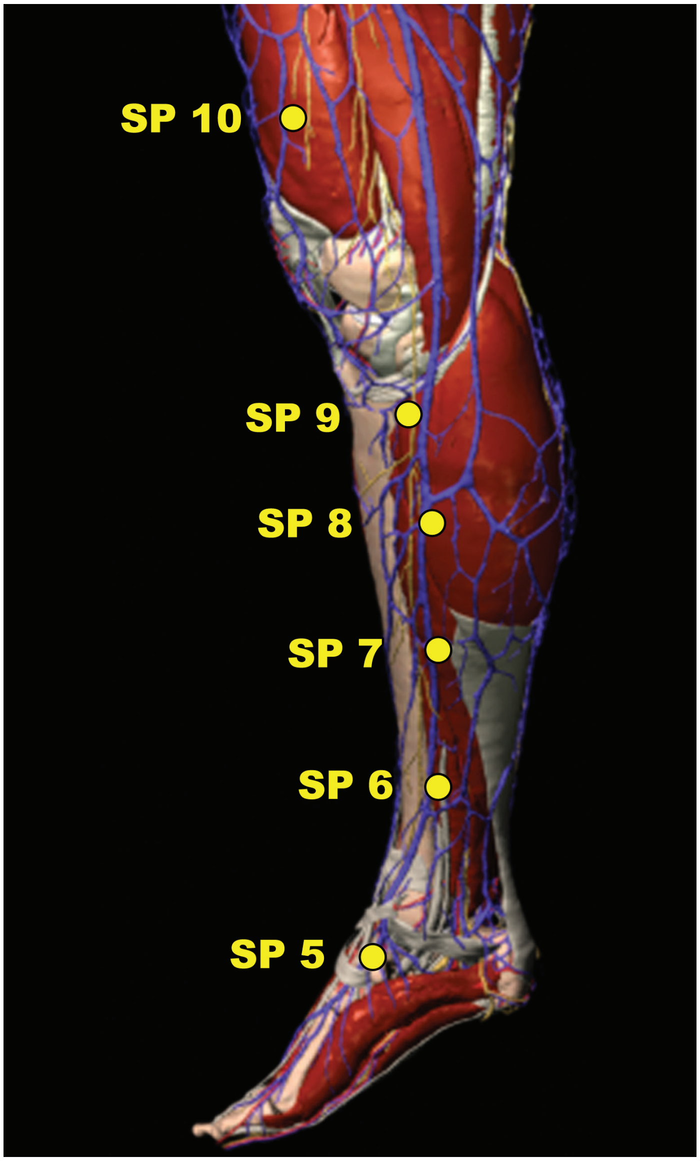

Figure 4-16. SP 7, "Leaking Valley", sits about mid-calf. This SP point follows the trend of its neighbors, hugging the tibia and the great saphenous vein while relating closely to the tibial and saphenous nerves. The similarity of structures associated with these points explains their frequently overlapping indications.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: As shown in Figure 4-17, the tibial nerve sits within reach of a needle entering SP 7. This presents the opportunity to neuromodulate both its motor aspects as well as issue input to the spinal cord segments that govern genitourinary activities.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch. Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin from the superficial veins. Because the perforating veins traverse this fascia at an oblique angle, muscular contraction and pressure within the compartment compress them. This promotes venous return to the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[1]

Figure 4-17. The name "Leaking Valley" for SP 7 describes the gulley, or valley, just caudal to the tibia, housing the great saphenous vein. Needling the vessel itself, as would have happened early in acupuncture's history, would have allowed blood to exit the vein and course down the valley. "Leaking Valley also could refer to an early physiologic idea that blood or fluid from this region leaked into the interstitial spaces to form pedal edema. In some ways, they were correct in terms of the linkage between venous insufficiency and valvular incompetence.

Indications and Potential Point Combinations

- **Local numbness or pain:** SP 7, BL 55, SP 6, KI 6. Evaluate for trigger points in the flexor digitorum longus, flexor hallucis longus, and tibialis posterior muscles.
- **Micturition disorders:** SP 7, SP 6, KI 3, BL 28, CV 3.

References

SP 8

Di Ji "Earth Pivot"

On the medial side of the leg, on the posterior border of the tibia, 3 cun distal to SP 9, on the line connecting SP 9 and the medial malleolus.

Muscles

- **Gastrocnemius muscle:** The gastrocnemius muscle raises the heel during ambulation. It flexes the leg at the knee, and plantarflexes the ankle if the knee is extended.
- **Soleus muscle:** Steadies the leg on the foot and plantarflexes the ankle, regardless of the position of the knee.
- **Flexor digitorum longus muscle:** The flexor digitorum longus flexes the lateral four pedal digits and plantarflexes the ankle. It helps support the longitudinal arch of the foot.
- **Flexor hallucis longus muscle:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It also assists the ankle in plantarflexion.
- **Posterior tibialis muscle:** This muscle inverts the foot and provides ankle plantarflexion.
- **Plantaris tendon:** Assists the gastrocnemius muscle in knee flexion and ankle plantarflexion.

Clinical Relevance: Trigger point pathology in the flexor digitorum longus near SP 8 refers pain down the spleen channel to the medial malleolus as well as the central plantar region of the foot. Needling into the tibialis posterior at this level may accentuate the referred pain and translate it more caudal along the gastrocnemius, to the calcaneal tendon, and over the plantar aspect of the foot.

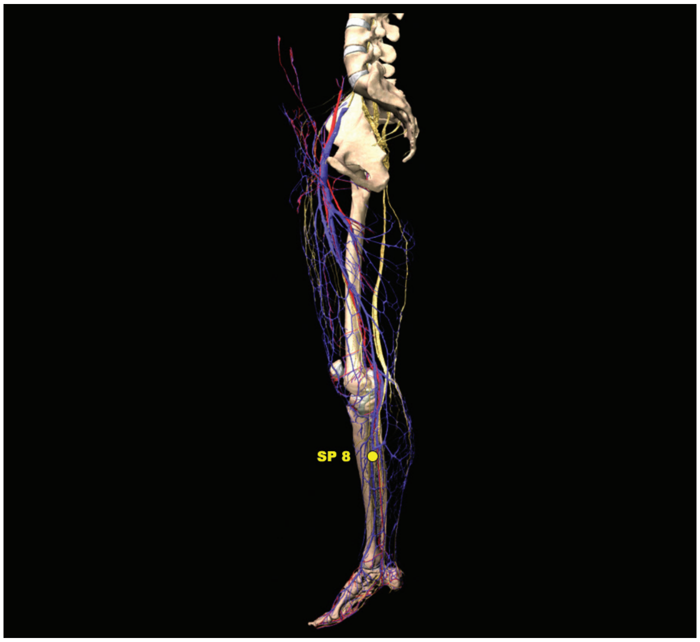

Figure 4-18. As with the other SP points on the calf, SP 8 follows the great saphenous vein and, a bit less directly, the tibial nerve.

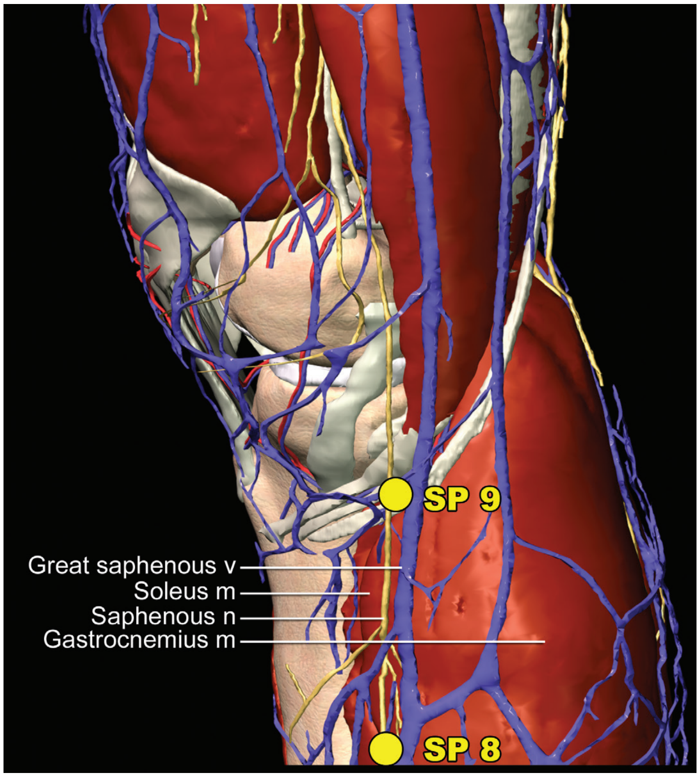

Figure 4-19. Chinese medicine divides the body into sections corresponding to "top, middle, and bottom", calling them "sky, man, and earth". As the "Earth Pivot", this point hinges between man and earth regions, and indications for its inclusion in treatment protocols relate to lower abdomen and pelvic activities such as digestion and reproduction. SP 8 as "Earth's Pivot" or "Earth's Crux" harkens back to the time in early China when acupuncturists regarded SP 8 as holding dominance over the lower region of the body, in the same way that SP 21 ("Great Embracement") oversees the upper body and ST 25 ("Celestial Pivot") the midsection. Alternatively, if one translates the "ji" in Di Ji as "cure" instead of "crucial point", then the name Di Ji becomes "Earth Cure". Pelvic limb points treat digestive disorders due to their linkage with the nucleus tractus solitarius and lumbosacral spinal cord segments. In Chinese medicine, the "Earth" domain refers to the process of digestion and assimilation. Thus, curing "Earth" problems refers to alleviating ailments such as diarrhea and irritable bowel syndrome.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: As shown in Figure 4-20, the tibial nerve sits within reach of a needle entering SP 8. This presents the opportunity to neuromodulate both its motor aspects as well as issue input to the spinal cord segments that govern genitourinary activities.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The

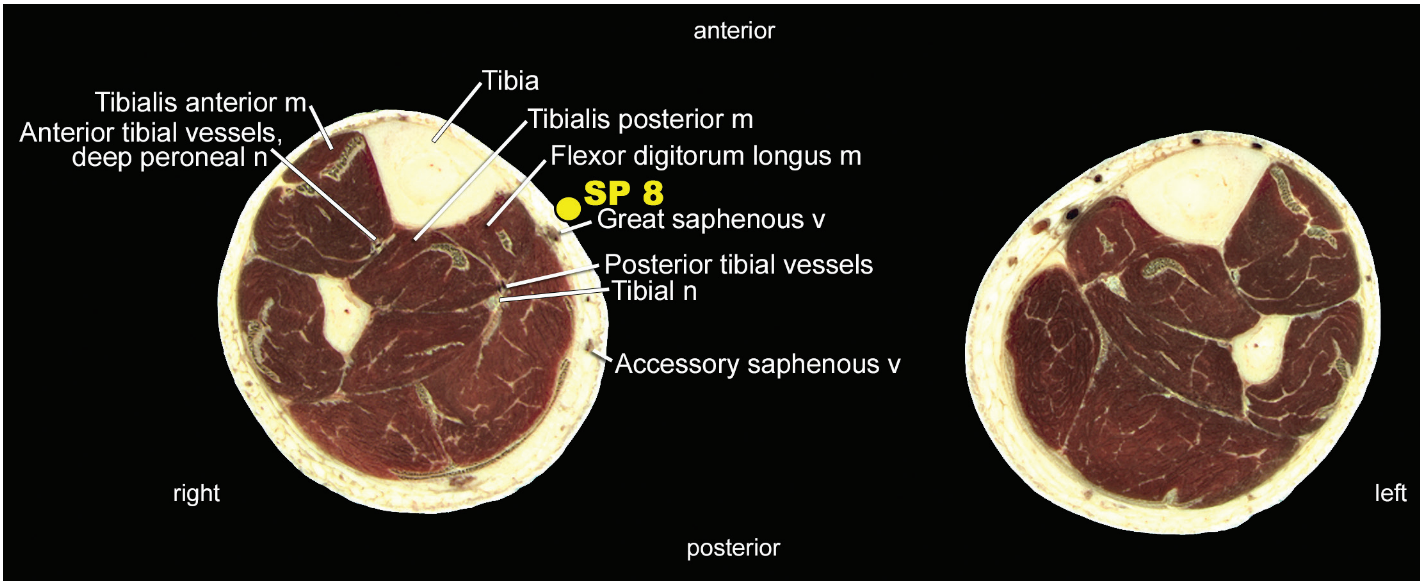

Figure 4-20. SP 8 lies close to the trigger point in the flexor digitorum longus muscle; pain here refers down the SP channel to SP 5 and then to the region surrounding KI 1 at the bottom of the foot.

posterior tibial artery provides a nutrient artery to the tibia.

- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch. Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin from the superficial veins. Because the perforating veins traverse this fascia at an oblique angle, muscular contraction and pressure within the compartment compress them. This promotes venous return to the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[2]

Indications and Potential Point Combinations

- **Menstrual and urogenital disorders:** SP 8, SP 6, CV 4, BL 23.
- **Acute digestive disorders, such as poor appetite, abdominal pain and distension:** SP 8, SP 6, ST 36, GV 20.
- **Urinary retention or incontinence:** SP 8, SP 6, KI 3, BL 27, BL 28.
- **Venous problems, especially edema:** SP 8, SP 6, SP 10, ST 36, BL 23, GV 20.

Evidence-Based Applications

- Case series reports SP 8 effective for **medial thigh pain, abdominal aching and distension, and chest pain on exertion.**[1]

SP 9

Yin Ling Quan "Yin Mound Spring"

On the medial side of the leg, in the depression posterior and inferior to the medial tibial condyle, between the posterior border of the tibia and the medial head of the gastrocnemius muscle.

Muscles and Tendons

- **Semimembranosus tendon:** Flexes the leg. Extends the thigh. When the knee is flexed, the semimembranosus muscle rotates the leg medially. When the thigh and leg are flexed, the semimembranosus extends the trunk.
- **Gastrocnemius muscle:** The gastrocnemius muscle raises the heel during ambulation. It flexes the leg at the knee, and plantarflexes the ankle if the knee is extended.
- **Semitendinosus tendon:** Flexes the leg. Extends the thigh. When the knee is flexed, the semitendinosus muscle rotates the leg medially. Then the thigh and leg are flexed, the semitendinosus extends the trunk.
- **Popliteus muscle:** Unlocks the knee and weakly flexes it.

Clinical Relevance: The "pes anserinus" ("foot of the goose") on the leg embodies the insertion of the conjoined tendons of the sartorius, gracilis, and semitendinosus muscles at SP 9. The pes anserinus is superficial to the tibial insertion of the medial collateral ligament. The bursa that separates the pes anserinus from the medial collateral ligament may become inflamed or irritated from overuse or injury leading to pain, swelling, and tenderness to palpation. "Pes anserine bursitis" has been proposed as a cause of chronic knee pain and weakness; palpation of the knee and surrounding regions should help identify contributing factors and trigger point pathology. Although many patients with this problem are athletes, pes anserine bursitis or swelling in this region may represent an extra-articular manifestation of gout,[12] mineralized fibroma of the tendon sheath,[13] or cystic periarticular knee lesions. The source of knee pain at SP 9 may be ambiguous, meaning that the term "pes anserinus tendino-bursitis syndrome" may be inaccurate if other structures are indeed involved.[14] The syndrome involves pain in the medial aspect of the knee, especially when ascending or descending stairs, tenderness to palpation, and possibly local edema. Differential diagnosis includes medial meniscus injury, osteoarthritis of the medial knee, radiculopathy of the L3-L4 nerve roots, and medial collateral ligament lesion.

Nerves

- **Anterior femoral cutaneous nerve (L2-L4):** Supplies the skin on the anterior and medial thigh regions.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Sciatic nerve (L4-S3):** Supplies the hamstring muscles (i.e., the

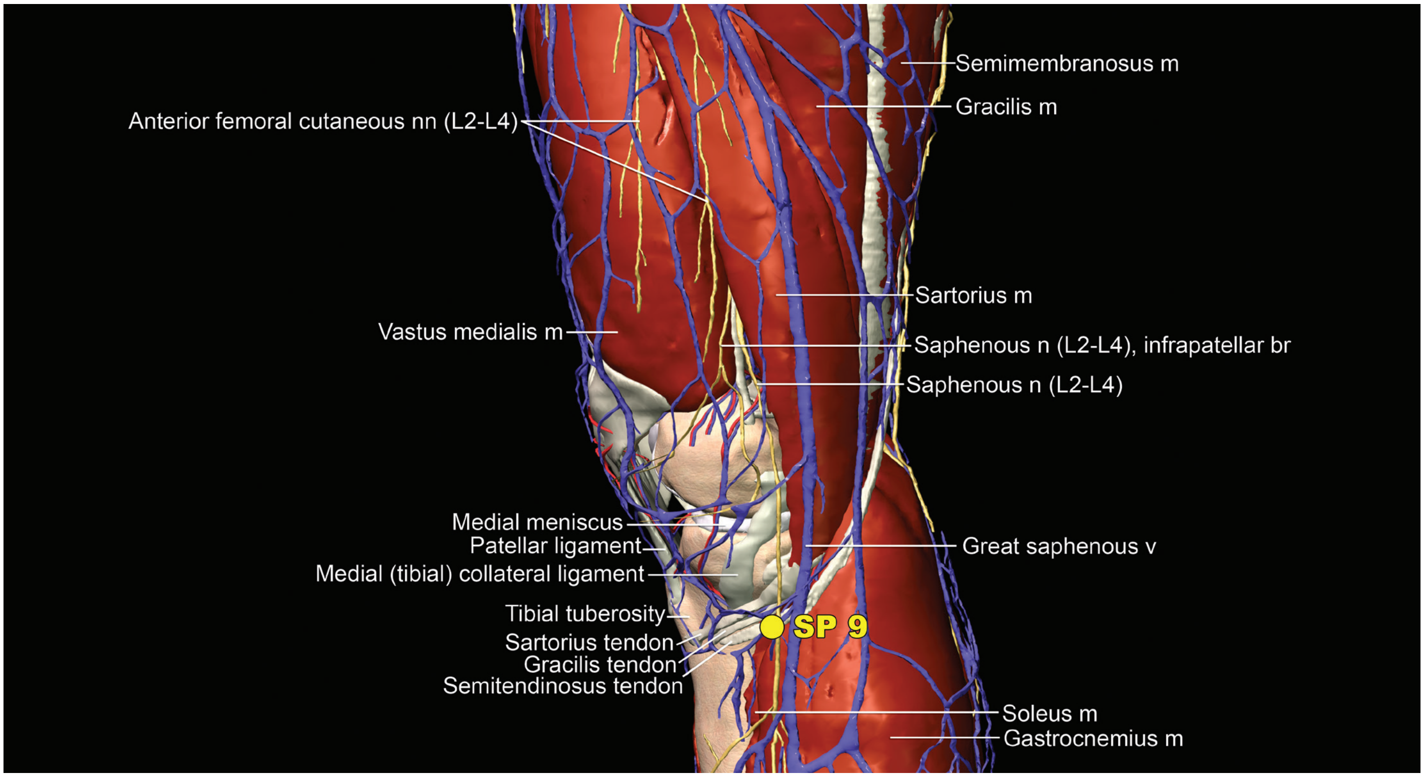

Figure 4-21. Regarding the name for SP 9 of "Yin Mound Spring", the "Mound" refers to the knee, "Yin" finds the locus on the medial aspect, and "Spring" alludes to the great saphenous vein. This view illustrates the pes anserinus, comprising a number of tendons, rich with proprioceptors that assist in knee stabilization, where they insert onto the tibia at SP 9. The gracilis tendon is located immediately superior to the semitendinosus insertion; the sartorius tendon overlaps the gracilis to form the pes anserinus. A bursa separates the pes anserinus from the medial collateral ligament. In addition to the fact that SP 9 overlies the confluence of three different tendons, in so doing it also relates to their three unique innervations, namely the obturator (for the gracilis), the tibial portion of the sciatic (for the semitendinosus), and the femoral (for the sartorius). Finally, note that many of the vessels comprising the genicular anastomosis appear in this image.

Figure 4-22. The saphenous nerve runs through SP 9, issuing branches to the skin and fascia of the anteromedial knee, leg, and foot, along the SP channel. The vascular associations of SP 9 show here as well, including the inferior medial genicular artery, the patellar anastomosis, and the great saphenous vein.

semimembranosus, semitendinosus, and long head of the biceps femoris muscles) by its tibial division (L5-S2). (The short head of the biceps femoris muscle is supplied by the common peroneal division (L5-S2).)

- **Tibial nerve (S1, S2):** This branch of the sciatic nerve supplies the soleus, gastrocnemius, plantaris, and popliteus muscles.

Clinical Relevance: Despite their common final destination, each muscle contributing to the pes anserinus carries a distinct innervation. That is, the femoral nerve supplies the sartorius, the obturator nerve innervates the gracilis, and the tibial portion of the sciatic nerve supplies the semitendinosus. Thus, needling or otherwise stimulating the point SP 9 impacts three different nerves.

John Hilton (1805-1878) was one of the first to note that patients with hip disease may also experience knee pain due to the common innervation of both joints.[15] He also lectured on his own "Hilton's Law", which states, "The same trunks of nerves, whose branches supply the groups of muscles moving a joint, furnish also a distribution of nerves to the skin over the insertions of the same muscles; and – what at this moment more especially merits our attention – the interior of the joint receives its nerves from the same source." Thus, the fact that the femoral, obturator, and tibial portion of the sciatic nerve all supply movers of the knee means, according to this law, that they each send branches to the overlying skin as well as the joint itself. This anatomical "law" highlights the relevance of SP 9 in treating disorders of the knee, including pain and proprioceptive abnormalities.

Vessels

- **Inferior medial genicular artery:** The inferior medial genicular artery participates in the formation of the genicular anastomosis – a network of vessels around the knee. It does so with the help of the other genicular arteries, including the lateral superior, medial superior, and lateral inferior arteries and three additional contributors: the descending genicular branch of the femoral artery, the descending branch of the lateral femoral circumflex artery, and the anterior recurrent branch of the anterior tibial artery. Genicular branches of the popliteal artery also supply the knee joint capsule and the ligaments of the knee. Supplies the patellar tendon, patella, and infrapatellar fat pad. Vessels in the vicinity of SP 9 contribute to the peripatellar anastomatic network (also known as "rete patellae" and the infrapatellar fat pad (of Hoffa).[16]
- **Popliteal artery:** Muscular branches of the popliteal artery supply the hamstring and gastrocnemius muscles, as well as the soleus and plantaris muscles.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch. Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein.
- **Medial inferior veins of the knee:** One of several deep veins around the knee that drain into the popliteal vein.

Clinical Relevance: Articular structures such as the knee receive abundant blood supply by means of anastomotic networks. However, numerous surgical procedures and trauma put the vascular supply of the patella at risk. They may acutely alter flow through direct vascular insult (e.g., pseudoaneurysm)

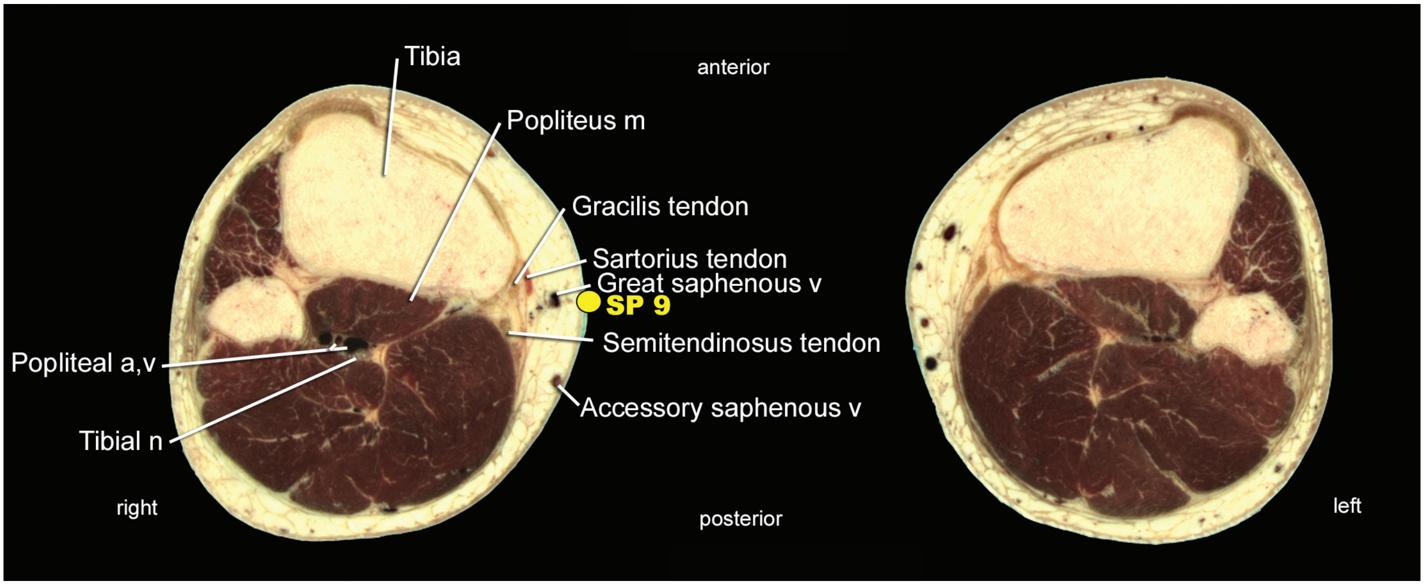

Figure 4-23. The depression palpable at SP 9 appears in this cross section as a triangular space between the tibia and the prominent muscle belly caudal (posterior) to the point, the medial head of the gastrocnemius muscle. Housed in the depression lives the pes anserinus, comprising the gracilis, sartorius, and semitendinosus tendons.

or, over the long term, drive sympathetic nerve stimulation, peripheral or central nervous system sensitization in chronic pain states. Acupuncture in this region may aid in restoring proper circulation by neuromodulating nervi vasorum and central nervous system pathways.

Similarly, blood flow compromise to the patellar tendon may put that structure at risk of developing patellar tendinopathy and, conceivably, rupture.[17]

Perhaps most importantly, the anterior cruciate ligament and supporting structures derives its blood supply from the genicular periarticular vascular plexus.[18] Soft tissues within the knee (i.e., the infrapatellar fat pad and synovium) mediate the blood supply to both cruciate ligaments. As such, negative impacts to these sites may impair nutrition to the cruciate ligaments and contribute to their degradation.

Varicose great saphenous veins contain unmyelinated C fibers in the external portion of the media as well as the internal part of the adventitia.[19] Histiocytes and other inflammatory cells exist scattered within the media. These findings provide evidence for the existence of a neurologic medium through which nociceptive signals from the vein reach the spinal cord and brain. Mast cells and concomitant inflammatory cells may serve to activate C fibers in the vessel wall of the varicose vein. The presence of nerves and inflammatory cells suggests an avenue through which neuromodulation through acupuncture and related techniques may impart healing effects for a disturbed milieu.

Indications and Potential Point Combinations

- **Knee pain:** SP 9, SP 10, ST 34, ST 36. Depending on the location of pain, check for trigger points in proximal muscles. For popliteal pain, palpate hamstrings in the BL 36, BL 37 region. Quadriceps triggers can send pain along the ST and SP channels; check SP 10 in the vastus medialis for cranial knee pain.
- **Edema of lower extremities, venous insufficiency:** SP 9, SP 8, SP 10, CV 6, ST 36.

Evidence-Based Applications

- Unilateral acupuncture for advanced **osteoarthritis of the knee** was effective as bilateral acupuncture, using SP 9, SP 10, ST 34, ST 36, and LI 4 on the ipsilateral hand.[1]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes.**[2]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combination with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome**, thereby offering an alternative to pharmacologic induction of ovulation.[3]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[4]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis** in women.[5]
- Acupuncture at LR 3, SP 6, SP 9, and ST 36 benefited patients with **chronic painful peripheral diabetic neuropathy**.[6]
- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis**, using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[7]
- Acupuncture at LI 4, ST 36, SP 6, and SP 9 reduced **discomfort and anxiety in patients undergoing colonoscopy.**[8]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[9]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per

ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[10]

- Acupuncture to SP 9, SP 6, CV 2, CV 3, CV 4, BL 23, BL 28, BL 32, and BL 39 demonstrated effectiveness in patients with **urinary retention** according to a case series.[20]
- Electroacupuncture at 2Hz applied to SP 9 increased **blood flow and perfusion in the spleen but not the liver,** while the same stimulation applied to LR 8 caused increased in the liver but not the spleen.[21]
- A study evaluating the effects of various acupuncture points on **stomach and heart electrical activity** found that SP 9, ST 36, SI 6, TH 5, LR 3, and LI 11 affected stomach activity more than other points tested, HT 5, GB 34, SP 9, and SI 6 influenced the electrointestinogram the most, and SP 9, LI 11, TH 5, and ST 36 increased electrocardiogram amplitude, while LR 3 decreased it.[22]
- **Reduces alpha-motoneuron excitability,** as measured with the Soleus H-reflex, when needled manually with GB 34 for 15 minutes.[11]

SP 10

Xue Hai "Sea of Blood"

On the medial side of the thigh, in a tender depression on the bulge of the vastus medialis muscle, 2 cun proximal to the superomedial angle of the patella.

(Alternate point location method: With the patient's left knee flexed and the practitioner facing the patient, the practitioner locates the point by cupping the knee with her right hand; SP 10 lies at the tip of the practitioner's fully extended thumb, laying at 45° from the index finger).

Muscles

- **Sartorius muscle:** The sartorius flexes, laterally rotates, and abducts the thigh at the hip joint. Flexes the leg at the knee.
- **Adductor magnus muscle:** Adducts the thigh. Comprises two parts – the adductor part and the hamstrings part. The adductor part flexes the thigh while the hamstrings part extends it.
- **Vastus medialis muscle:** Extends the leg at the knee joint. Dubbed the "buckling knee muscle" by Travell and Simons, the vastus medialis harbors trigger points that not only cause pain but also inhibit muscle function, leading to unexpected knee buckling.[1]

Clinical Relevance: Trigger points in the adductor magnus muscle at SP 10 and proximal to it refer pain along the remainder of the SP channel, from SP 10 to the groin.

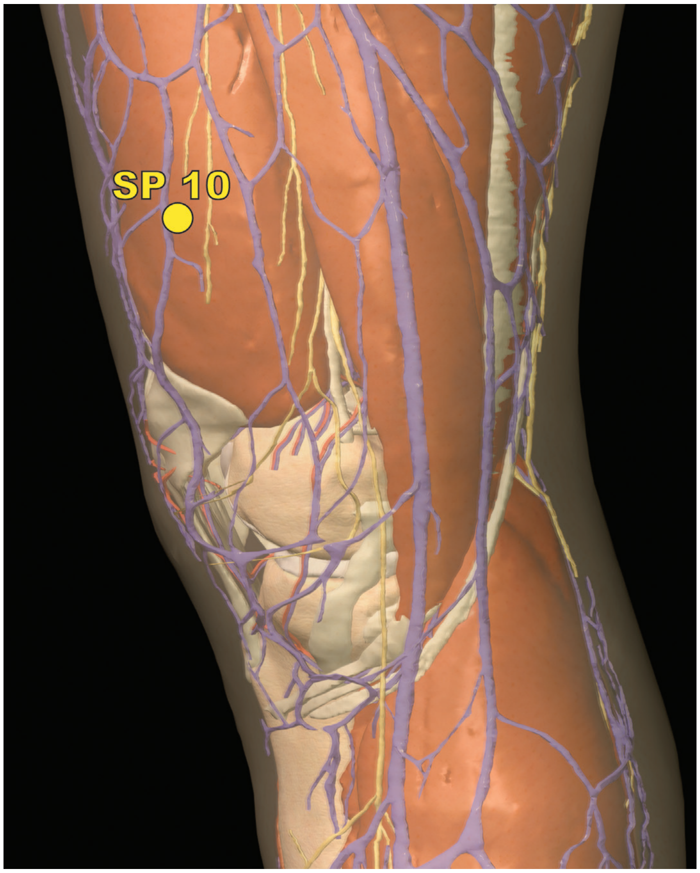

Figure 4-24. The indications for SP 10, the "Sea of Blood", relating to genitourinary problems likely stems from the spinal segmental overlap of the nerve supply for this point with that of the pelvic viscera.

Neuromuscular and strength training programs designed to target the quadriceps (including the vastus medialis muscle) improve limb strength and performance in middle-aged patients with degenerative meniscus tears.[13] Introducing acupuncture for neuromodulation and pain control may further support these improvements.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Anterior femoral cutaneous nerve (from the femoral nerve, L2-L4):** Supplies the skin on the thigh's anterior and medial aspects.
- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus (the adductor part) and obturator externus muscles.
- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. It supplies the skin on the anteromedial thigh and supplies the hip and knee joints. It supplies the anterior thigh muscles, including the sartorius muscle.

Clinical Relevance: Most sources indicate that the saphenous nerve is purely sensory. Various surgical procedures and traumatic events may injure it and compromise its function. Strenuous exercise may also negatively impact the nerve by causing a nerve entrapment.[14] Sites where the saphenous nerve may become entrapped include 1) The adductor canal where the saphenous nerve splits from the femoral and courses independently along the fascial channel through the adductor canal, and 2) The locus where the nerve leaves the adductor canal to exit the fascial layer between the sartorius and gracilis muscles. Conceivably, neuropathy of the saphenous nerve can lead to persistent, medial knee pain.[15] Palpating for myofascial restriction in the medial thigh may aid in determining the site of saphenous nerve compression or entrapment.

Vessels

- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.
- **Perforating veins:** Drain blood from the thigh muscles.
- **Deep vein of the thigh:** The perforating veins terminate in the deep vein of the thigh.
- **Descending genicular artery, articular branch:** This artery arises from the femoral artery and gives rise to muscular and articular branches. It anastomoses with the superior and inferior medial genicular arteries. The descending genicular artery passes through the opening in the adductor magnus tendon to branch into a saphenous and articular branch. The saphenous branch of the descending genicular artery follows the saphenous nerve along the medial aspect of the knee and the SP channel. The articular branches anastomoses with the medial superior genicular artery within the substance of the

vastus medialis muscle, not far from SP 10.

Clinical Relevance: SP 10 often appears in treatment protocols for knee pain, including that from anterior cruciate ligament injury. Blood supply to the knee in general arrives from branches of the descending genicular artery, the medial and lateral superior genicular arteries, the medial and lateral inferior genicular arteries, the middle genicular artery, and the anterior and posterior tibial recurrent arteries.[16]

Indications and Potential Point Combinations

- **Knee pain:** SP 10, SP 9, ST 34, ST 36, GB 34, Xiyan (on either side of the patellar ligament, Heding (at the apex of the patella). The trigger point in the vastus medialis muscle refers to the anteromedial knee. Consider myofascial contributions to knee pain from elsewhere, too, coupled with potential arthrodial problems. Additional trigger points.
- **Menstrual and gynecologic disorders such as menorrhagia, irregular menstruation, dysmenorrhea:** SP 10, SP 6, BL 32, BL 23, GV 4, GV 20, CV 6.
- **Skin disorders:** urticaria, eczema, and allergy: SP 10, ST 36, LI 4, LI 11, GV 14, SP 6.

Evidence-Based Applications

- The four points LI 11, SP10, SP 6, and ST 36 treat **acute urticaria.**[2]
- A case series using needling, bleeding, and cupping to treat **erysipelas** reported "good results" using SP 10, SP 1, and "visible veins".[3]
- Repeated acupuncture at ST 36, LI 11, SP 10, and GV 14 significantly decreased leukocyte and lymphocyte values in healthy humans, although cortisol and norepinephrine plasma levels remained unchanged. The mechanism whereby acupuncture affected **leukocyte circulation** was unknown.[4]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[5]
- A case series evaluating acupuncture for **poison ivy contact dermatitis** reported effectiveness with the acupuncture points SP 10, LI 11, and ST 36.[6] These points were also effective in reducing the severity and preventing recurrences of **herpes simplex infections**[7] **and in clearing psoriasis lesions.**[8]
- Unilateral acupuncture for **advanced osteoarthritis of the knee** was effective as bilateral acupuncture, using SP 9, SP 10, ST 34, ST 36, and LI 4 on the ipsilateral hand.[9]
- Acupuncture at CV 17, CV 12, CV 6, ST 36, and SP 10 conferred protective effects on **cognitive impairments caused by multiinfarction dementia** in rats, suggesting it may benefit patients with vascular dementia.[10]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation:

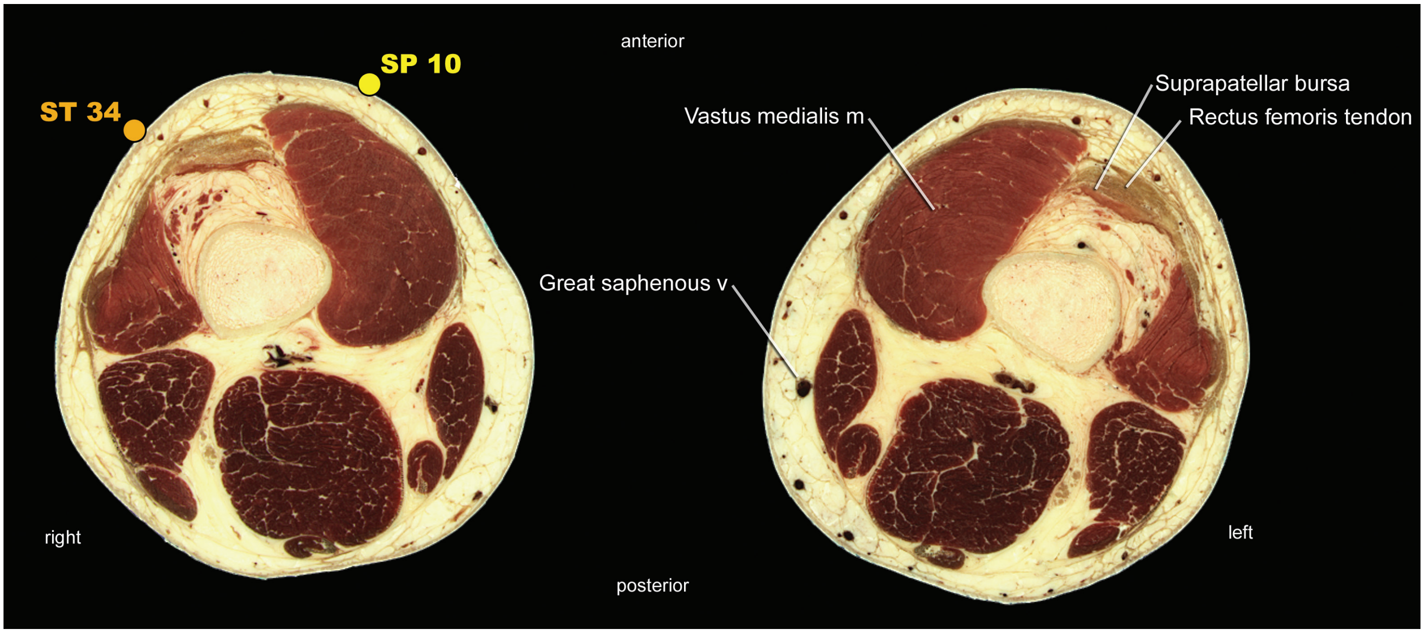

Figure 4-26. Although SP 10 is a "Sea of Blood" point, the great saphenous vein has diverged from the SP channel at this level. The appellation likely refers to the influence of SP 10 on menstruation rather than a vascular passageway.

LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[11] • Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in **improvement in sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[12]

SP 11

Ji Men "Winnower Gate" or "Basket Gate"

On the medial aspect of the thigh, 6 cun proximal to SP 10, on the line between SP 10 and SP 12.

Muscles

- **Sartorius muscle:** The sartorius flexes, laterally rotates, and abducts the thigh at the hip joint. Flexes the leg at the knee.
- **Adductor magnus muscle:** Adducts the thigh. Comprises two parts – the adductor part and the hamstrings part. The adductor part flexes the thigh while the hamstrings part extends it.
- **Adductor longus muscle:** Adducts the thigh.
- **Adductor brevis muscle:** Adducts the thigh. Can also flex the thigh.
- **Vastus medialis muscle:** Extends the leg at the knee joint.

Clinical Relevance: Trigger points in the adductor magnus muscle at SP 11 refers pain proximad, toward the groin, as well as distad, toward the knee, following the SP channel. Finding SP 11 more medial and posterior (caudal) than depicted in Figure 4-28 would more directly impact the adductors.

Neuromuscular and strength training programs improve limb strength and performance in middle-aged patients with degenerative meniscus tears who have not undergone surgical repair.[1] Introducing acupuncture for neuromodulation and pain control may further support these improvements.

The quadriceps group may weaken following anterior cruciate ligament injury and reconstruction.[2] Inhibition of quadriceps muscle function, especially that of the vastus medialis, contributes to this weakness. Intra-articular swelling negatively impacts vastus medialis strength. Neuromodulating with acupuncture and related techniques may help repair strength and coordination by stimulating muscle afferents near SP 11 and SP 10.

The vastus medialis counterbalances the lateral pull of the vastus lateralis on the patella. An imbalance in timing of the muscle contraction of both muscles may lead to patellofemoral tracking problems, lateral subluxation of the patella, retropatellar pain, and articular cartilage degeneration.[3] Patellar malalignment can lead to tension in the hamstrings, iliotibial band, hip rotators, quadriceps muscle group, and calcaneal tendon. Acupuncture and related techniques applied to the vastus medialis (as at SP 11 and SP 10) and the vastus lateralis (ST 32, ST 33, and 34) may aid in rebalancing firing patterns within the quadriceps group.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Anterior femoral cutaneous nerve (from the femoral nerve, L2-L4):** Supplies the skin on the thigh's anterior and medial aspects.
- **Obturator nerve (L2-L4):** The obturator nerve branches into anterior and posterior branches. The anterior branch supplies adductor muscles, including the adductor longus and brevis muscles, the gracilis, and the pectineus muscles. The posterior branch supplies the adductor magnus (the adductor part) and obturator externus muscles.

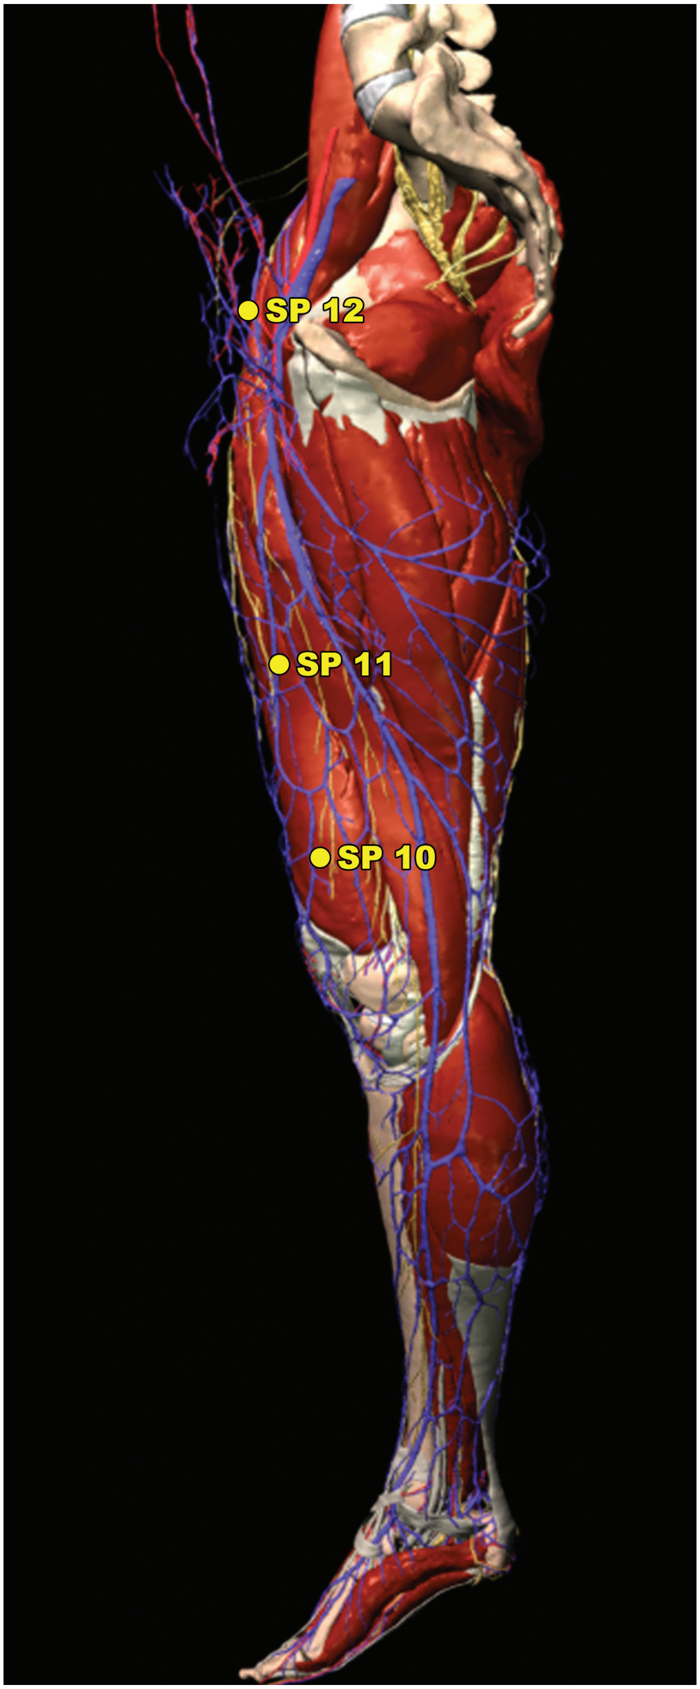

Figure 4-27. The name for SP 11, "Winnower Gate", indicates that this point lands where the winnowing basket would sit as the person doing the winnowing squats and holds the basket between the thighs. Note the obvious diagonal groove descending at this level from the cranial to caudal thigh that could couch such a basket. "Winnowing" refers to the process of separating the wheat (or other grains) from the chaff.

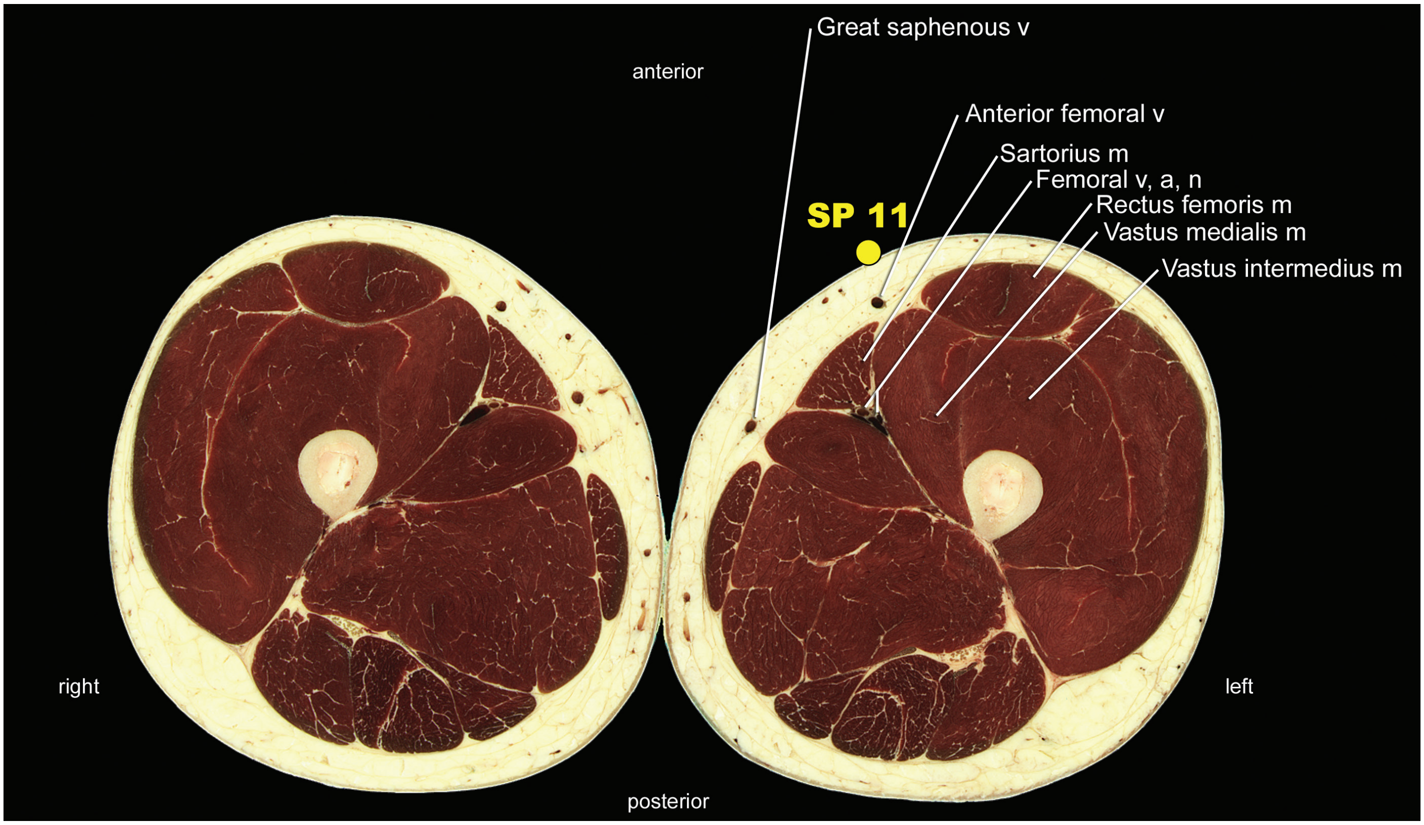

Figure 4-28. At SP 11, the SP channel relates more closely to the anterior femoral vein and the femoral nerve, artery, and vein, leaving the close relationship it shared with the great saphenous vein below the knee.

- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. It supplies the skin on the anteromedial thigh and supplies the hip and knee joints. It supplies the anterior thigh muscles, including the sartorius muscle.

Clinical Relevance: Most sources indicate that the saphenous nerve is purely sensory. Various surgical procedures and traumatic events may injure it and compromise its function. Strenuous exercise may also negatively impact the nerve by causing a nerve entrapment.[4] Sites where the saphenous nerve may become entrapped include 1) The adductor canal where the saphenous nerve splits from the femoral and courses independently along the fascial channel through the adductor canal, and 2) The locus where the nerve leaves the adductor canal to exit the fascial layer between the sartorius and gracilis muscles. Conceivably, neuropathy of the saphenous nerve can lead to persistent, medial knee pain.[5] Palpating for myofascial restriction in the medial thigh may aid in determining the site of saphenous nerve compression or entrapment.

Vessels

- **Femoral artery:** Supplies the anteromedial surface of the thigh as well as the anterior surface.
- **Femoral vein:** The femoral vein arises from the popliteal vein.
- **Perforating veins:** Drain blood from the thigh muscles.
- **Deep vein of the thigh:** The perforating veins terminate in the deep vein of the thigh.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins as the union of the dorsal vein of the great toe and the pedal dorsal venous arch. Along its course it anastomoses with the small saphenous vein and finally empties into the femoral vein.

Clinical Relevance: The SP channel follows either the great saphenous vein or, as shown in Figure 4-28, the anterior femoral vein and femoral artery and vein.

Indications and Potential Point Combinations

- **Urinary retention, anuresis, dysuria, cystitis:** SP 11, SP 6, KI 3, BL 28, BL 32, GV 3.
- **Inguinal inflammation, pain, non-cancer-related inguinal lymphadenopathy:** SP 11, tender inguinal region points (LR 12, ST 29, ST 30, SP 12,SP 13), KI 27.
- **Local thigh pain:** SP 11, check for trigger points in the adductors, the sartorius, and the vastus medialis muscle.

SP 12

Chong Men "Surging Gate"

On the inguinal region, just proximal to the inguinal ligament, lateral to the external iliac artery.

(Alternate location: on the base of the femoral triangle, just inferior to the inguinal ligament, lateral to the femoral artery.) Approximately the site of femoral nerve block.[1]

Caution with deep needling: Several prominent neurovascular structures exist beneath this point, as seen in Figure 4-30.

Muscles

- **Iliopsoas muscle:** The main flexor of the thigh. If the thigh is maintained in a fixed position, the iliopsoas muscle flexes the trunk against the hip. The iliopsoas also serves as a postural muscle that prevents hyperextension of the hip when an individual stands.
- **Sartorius muscle:** The longest single muscle in the body, the sartorius courses the length of the thigh, having formed the lateral border of the femoral triangle at its origin. The sartorius assists in hip flexion, abduction, and lateral rotation. It also helps flex the knee. Take a peek at KI 1 on your own foot and you've just demonstrated all four actions of the sartorius.

Clinical Relevance: The best way to consider the impact of SP 12 on local musculature is to view the cross section at this level, depicted in Figure 4-30. This image illustrates how superficial needling can impact the sartorius muscle with the needle angled in a lateral direction or the iliopsoas muscle when angled perpendicular to the body. A more extreme and deep needle insertion may touch the pectineus muscle but risks injury of the externa iliac artery and vein as well as the femoral nerve. Trigger points from the iliopsoas cause pain sensation to travel up the ipsilateral paraspinal lumbar musculature and down the middle anterior portion of the thigh. Sartorius trigger points send pain along the muscle itself. Pectineus pain from trigger point pathology stays in the region over the muscle in the groin.

Nerves

- **Subcostal nerve (T12):** Supplies the skin in this region. The subcostal nerve communicates with the iliohypogastric, providing a nerve branch to the pyramidalis muscle and a lateral cutaneous branch that supplies sensation to the hip. The subcostal nerve, i.e., the anterior division of the 12th thoracic spinal nerve, is larger than the other intercostal nerves.
- **Iliohypogastric nerve (Superior branch of the ventral (anterior) ramus of L1 spinal nerve; occasionally receives contributions from T12, the subcostal nerve):** The iliohypogastric nerve branches into anterior and lateral cutaneous nerves. The lateral branch supplies the skin over the iliac crest while the anterior branch supplies the skin superior to the pubic region. This nerve also innervates the internal oblique and transverse abdominal muscles. The right and left sympathetic trunks receive white rami communicantes from the ventral rami of the L1-L3 spinal nerves and send gray rami communicantes to these nerves. This provides for the opportunity to engage in sympathetic neuromodulation by sending afferent input into the L1 spinal cord segment through SP 12 and the anterior branch of the iliohypogastric nerve.
- **Ilioinguinal nerve (Inferior branch of the ventral (anterior) ramus of L1 spinal nerve; occasionally receives contributions from T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.
- **Genitofemoral nerve (L1, L2):** Divides into genital and femoral branches. The femoral branch supplies the skin overlying the femoral triangle. The genital branch supplies the labia majora in females and the scrotum in males.
- **Femoral nerve (L2-L4):** The femoral nerve arises from the lumbar plexus and is its largest branch. It supplies the skin on

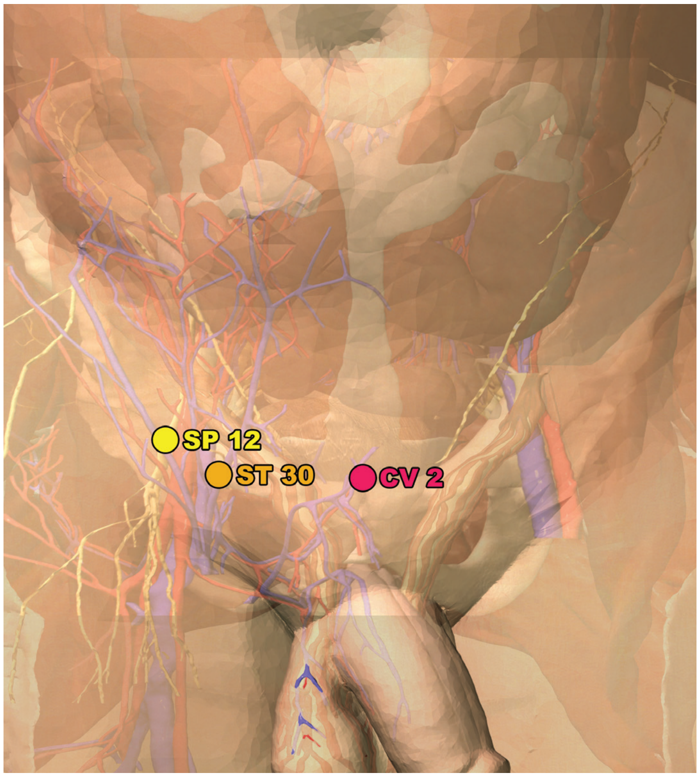

Figure 4-29. For SP 12, "Surging Gate" describes the pulsating femoral artery at the gateway to the pelvis where vessels and nerves are entering and exiting the pelvis. SP 12 marks the site where SP line points' visceral impact surges to the fore and musculoskeletal connections become less important. The anatomy explains why: SP 12 to SP 21 exist on the abdomen and thorax. Structures beneath the body wall carry on the vegetative functions of digestion, elimination, reproduction, circulation, and respiration. While certain applications for body wall pain and nerve entrapment will also fall under the purview of SP line truncal points, the main benefits will derive from somatovisceral reflex modulation.

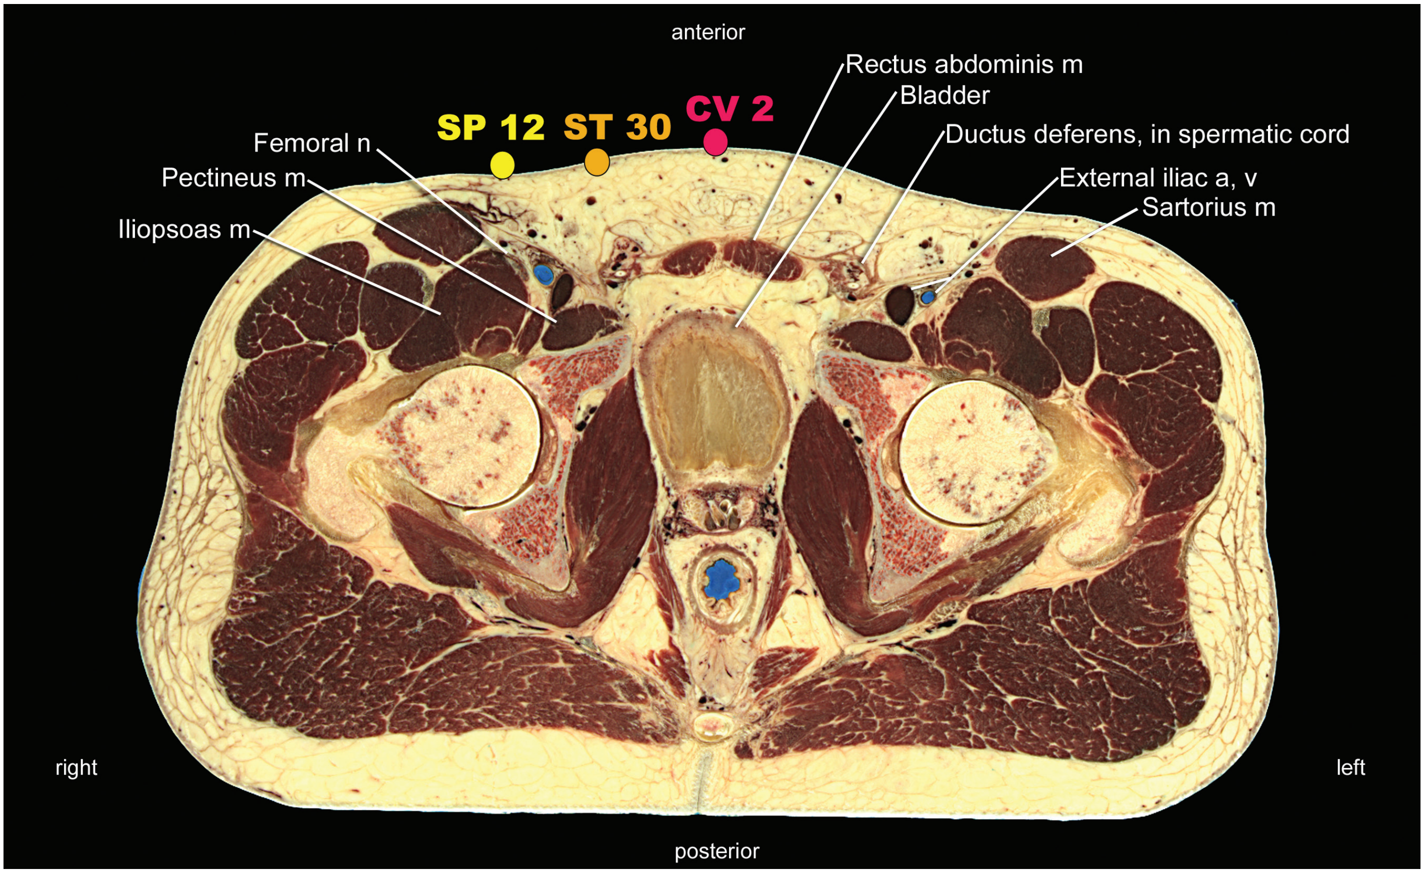

Figure 4-30. This cross section at the level of SP 12 compares the structures within the reach of an acupuncture needle to those associated with its neighbors, ST 30 and CV 2. Of note as well is how the SP channel has moved to lateral to the ST line.

the anteromedial thigh and supplies the hip and knee joints. Its anterior (or superior) branch supplies the anterior thigh muscles, including sensory, motor, and proprioceptive function for the sartorius muscle.

Nerves: The multiplicity of nerves supplying this region speaks to the multifaceted effects of SP 12. Many of the nerves reflex to pelvic organs and genitourinary function through spinal segmental overlap of somatic and sympathetic pathways. The lumbar plexus, comprised of the ventral rami of L1 through L4 spinal nerves and accompanied by a branch of the T12 spinal nerve ventral ramus, forms several of the nerves that provide nerve input to SP 12. They include the: iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.[3] The jobs these nerves do in terms of communicating between the soma and viscera along with supplying sensation, motor function, and proprioception to muscles of the pelvis and lower limb, make SP 12 a neural traffic highway ferrying signals up and down, in and out.

Vessels

- **Superficial epigastric artery**: Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior epigastric artery**: Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall. It arises from the external iliac artery just superior to the inguinal ligament.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and from there, into the superior vena cava.
- **Superficial circumflex iliac artery:** Provides blood to the subcutaneous tissue and skin overlying the inferior region of the anterolateral abdominal wall. Arises from the femoral artery.
- **Superficial circumflex iliac vein:** This vein, along with the superficial epigastric vein, provides a collateral route for return of abdominopelvic venous blood when the inferior vena cava becomes obstructed or ligated. Like the superficial epigastric and the inferior and superior epigastric veins, the superficial circumflex iliac vein lacks valves, and thus serves as conduits for venous return to the heart. Usually, the superficial circumflex iliac veins and the superficial epigastric veins would serve as tributaries of the great saphenous vein, which drains into the inferior vena cava (IVC). Since these veins anastomose in the subcutaneous tissues of the anterolateral body wall with tributaries of the axillary vein (usually the lateral thoracic vein), blood can flow through this subcutaneous collateral circulation

pathway instead of the great saphenous vein/IVC if that drainage route becomes unavailable. This subcutaneous collateral pathway is called the thoracoepigastric vein.

- **Deep circumflex iliac artery:** Supplies the iliacus muscle and the inferior region of the anterolateral abdominal wall.
- **External iliac artery:** Gives rise to the inferior epigastric and deep circumflex iliac artery.

Clinical Relevance: The various superficial venous channels that course over the abdomen provide alternative sources of vascular access if attempts at peripheral venipuncture fail for patients with portal hypertension due to liver cirrhosis or other causes. Accessing superficial vessels avoids the risks associated with pursuing central venous access.[4] Inferior vena caval obstruction (e.g., from thrombosis or tumor) or its congenital absence can cause the paraumbilical and abdominal subcutaneous veins to become patent.[5] The continued close relationship between the SP channel and underlying veins serves as a reminder of acupuncture's origins as a bloodletting procedure.

Indications and Potential Point Combinations

- **Orchitis:** SP 12, ST 29, SP 6, CV 2.
- **Endometriosis:** SP 12, SP 4, SP 6, CV 4, PC 6.
- **Postpartum hemorrhage:** SP 12, SP 10, CV 4.
- **Pain of inguinal hernia repair:** SP 12, SP 13, ST 30, ST 29, CV 2.
- **Restricted range of motion of the hip, local pain:** Check for local trigger points and sources of referred pain, including SP 12 over the pectineus, SP 11 over the adductor magnus and the vastus medialis muscles.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[2]

SP 13

Fu She "Bowel Abode"

On the lower abdomen, on the lateral border of the rectus abdominis muscle (linea semilunaris), 4 cun lateral to the anterior midline, level with CV 3.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: Rectus sheath hematoma can result from hemorrhage into the rectus muscle due to rupture of either the superior or inferior epigastric arteries or their branches, as well as a tear of the rectus abdominis muscle. Fascial strains may affect this region as well, caused by strenuous exercise or stretching, such as with yogic postures.[1] Rectus sheath hematoma may be more common in women on oral anticoagulants who strain during defecation or coughing.[2] Acupuncture and related techniques may lessen fascial restrictions, pain, inflammation, and myofascial dysfunction in tissues associated with the rectus sheath.

Muscles

- **External oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis aponeurosis:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence who have difficulty exercising the pelvic floor muscles.[3] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence.

Nerves

- **Subcostal nerve (T12):** Supplies the skin in this region.
- **1st lumbar nerve (L1):** Contributes to nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the

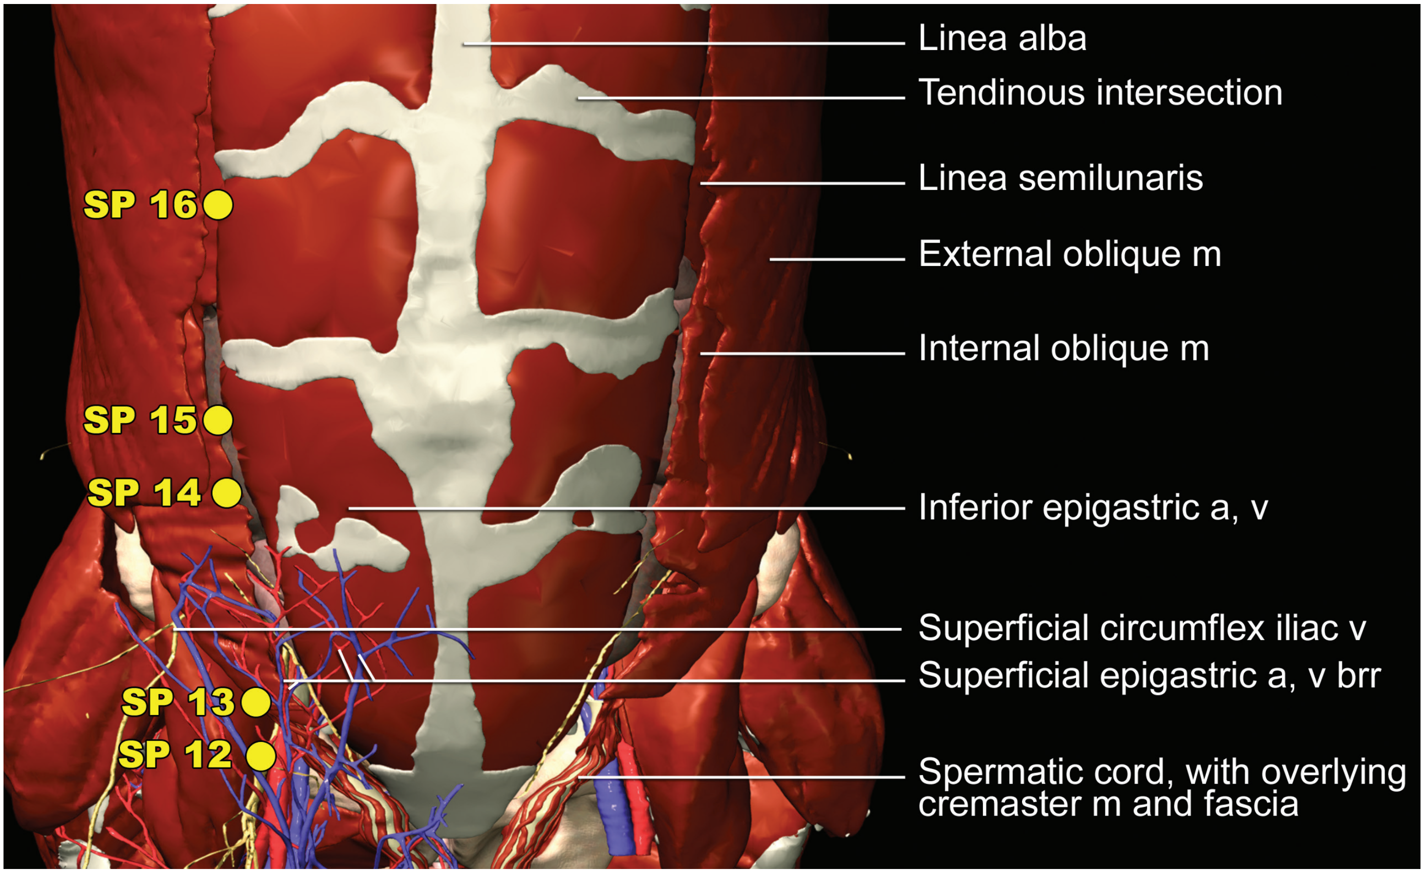

Figure 4-31. SP 13, "Bowel Abode" indicates the value of this point for treating bowel-related dysfunction. In fact, even on this muscle layer, the underlying intestines can be seen through the linea semilunaris. The semi-transparent muscle layer reveals the relative locations of the intestines to SP 13. In addition, seeing through the musculature reveals how the inferior epigastric vessels lie deep to the abdominal wall while the superficial epigastric vessels sit above it. Note, as well, the network of nerves and vessels at and around SP 13 that may suffer injury from transverse incisions to the lower abdominal wall.

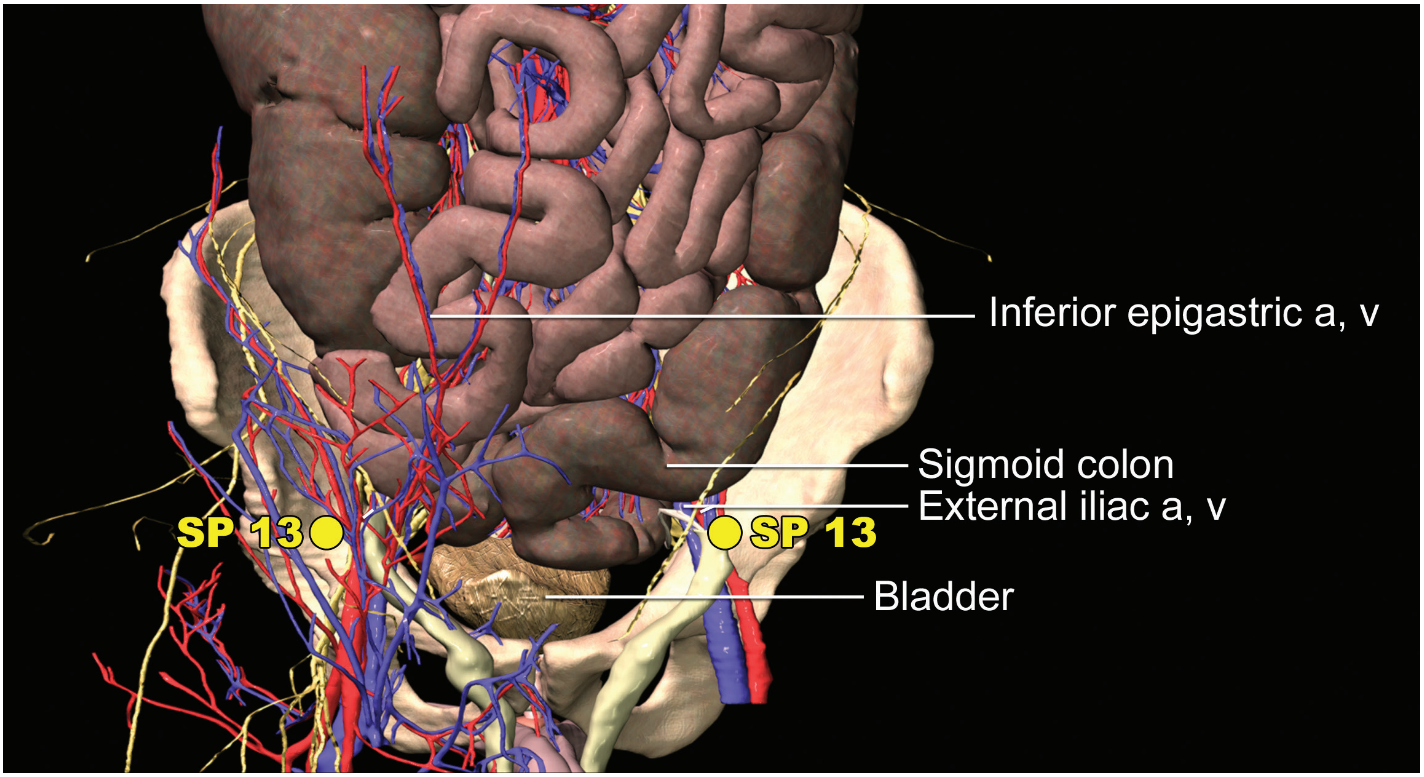

Figure 4-32. Acupuncture stimulation of nerves supplying SP 13, like SP 12, influences pelvic organ function through cutaneovisceral, spinal segmental, and myofascial relationships and connections. The soma at SP 13 receives innervation from the L1 spinal cord segment, allowing the opportunity to modulate autonomic activity in the pelvis via crosstalk with nerves of the lumbar plexus that issue sympathetic fibers to abdominopelvic structures.

periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: The iliohypogastric nerve, one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen, especially when the incision extends lateral to the inferior rectus abdominis muscle. Surgeries with such incisions may include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Acupuncture and related techniques in the vicinity of SP 13 may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[4] Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

The multiplicity of nerves supplying this region speaks to the multifaceted effects of SP 13. Many of the nerves reflex to pelvic organs and genitourinary function through spinal segmental overlap of somatic and sympathetic pathways. The lumbar plexus, comprised of the ventral rami of L1 through L4 spinal nerves and accompanied by a branch of the T12 spinal nerve ventral ramus, forms several of the nerves that provide nerve input to SP 13. They include the: iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.[5] The jobs these nerves do in terms of communicating between the soma and viscera along with supplying sensation, motor function, and proprioception to muscles of the pelvis and lower limb, make SP 13, like its neighbor SP 12, a neural traffic highway ferrying signals up and down, in and out.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the internal thoracic, subclavian and brachiocephalic veins, and

from there, into the superior vena cava.

Clinical Relevance: The various superficial venous channels that course over the abdomen provide alternative sources of vascular access if attempts at peripheral venipuncture fail for patients with portal hypertension due to liver cirrhosis or other causes. Accessing superficial vessels avoids the risks associated with pursuing central venous access.[6] Inferior vena caval obstruction (e.g., from thrombosis or tumor) or its congenital absence can cause the paraumbilical and abdominal subcutaneous veins to become patent.[7] The continued close relationship between the SP channel and underlying veins serves as a reminder of acupuncture's origins as a bloodletting procedure.

Indications and Potential Point Combinations

- **Inguinal and hip pain:** SP 13, check for quadratus lumborum trigger points in the BL 21-BL 25 region that could refer to the inguinal/hip/gluteal region.
- **Constipation:** SP 13, CV 6, ST 36, ST 25, BL 25, BL 32, GV 3.
- **Orchitis:** SP 12, ST 29, SP 6, CV 2.
- **Vaginal infection, ovarian pain:** SP 13, ST 30, CV 4, SP 4, PC 6.
- **Endometriosis:** SP 12, SP 4, SP 6, CV 4, PC 6.
- **Postpartum hemorrhage:** SP 12, SP 10, CV 4.
- **Hernia, pain of inguinal hernia repair:** SP 12, SP 13, ST 30, ST 29, CV 2.
- **Restricted range of motion of the hip, local pain:** Check for local trigger points and sources of referred pain, including SP 12 over the pectineus, SP 11 over the adductor magnus and the vastus medialis muscles.

SP 14

Fu Jie "Abdomen Knot" or "Abdominal Bind"

On the lower abdomen, on the lateral border of the rectus abdominis muscle (linea semilunaris), 3 cun proximal to SP 13, 4 cun lateral to the anterior midline, level with CV 7.

Caution needling here. Deep needling may enter the cecum. See Figure 4-36.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: Rectus sheath hematoma can result from hemorrhage into the rectus muscle due to rupture of either the superior or inferior epigastric arteries or their branches, as well as a tear of the rectus abdominis muscle. Fascial strains may affect this region as well, caused by strenuous exercise or stretching, such as with yogic postures.[1] Rectus sheath hematoma may be more common in women on oral anticoagulants who strain during defecation or coughing.[2] Acupuncture and related techniques may lessen fascial restrictions, pain, inflammation, and myofascial dysfunction in tissues associated with the rectus sheath.

Muscles

- **External oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis aponeurosis:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger point pathology in the abdominal oblique muscles such as at SP 14 may send referred pain in various directions across the abdomen, including toward the ipsilateral or contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia, leading to a variety of diagnostic enigmas and confusion.

Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence that have difficulty exercising the pelvic floor muscles.[3] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence.

Nerves

- **11th intercostal nerve:** Supplies the skin in this region.
- **1st lumbar nerve:** Contributes to nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves and L1):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: The iliohypogastric nerve, one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen, especially when the incision extends lateral to the inferior rectus abdominis muscle. Surgeries where this may happen include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Acupuncture and related techniques in the vicinity of SP 14 may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[4] Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as

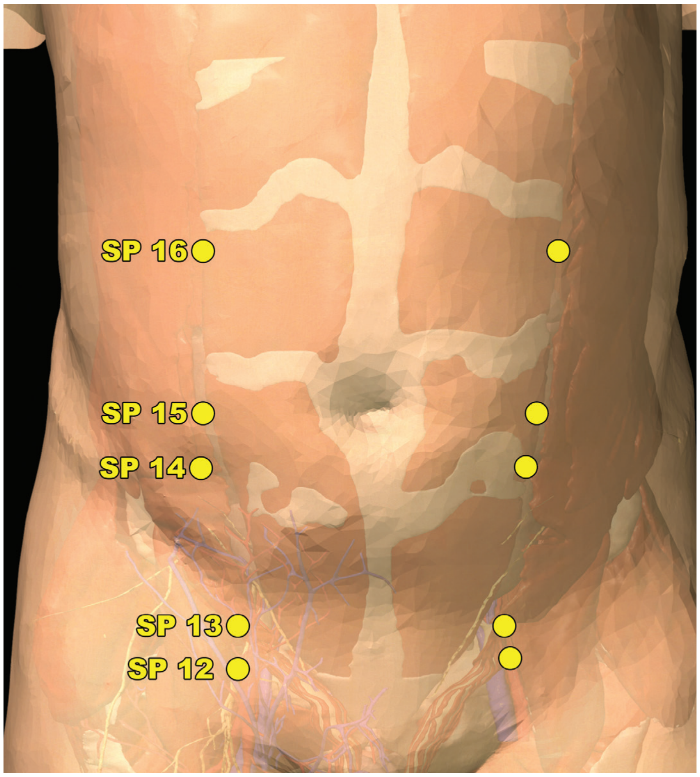

Figure 4-34. SP 14 appears here in the context of its neighbors' locations on the lower abdomen. The line-up of SP points along the linea semilunaris coincides with sites of neurovascular entrapment on the abdominal wall. SP points along the linea semilunaris receive dual cutaneous nerve input; namely 1) the lateral cutaneous branches of the intercostals, subcostal, and iliohypogastric nerves, as well as 2) the anterior cutaneous branches of these same nerves.

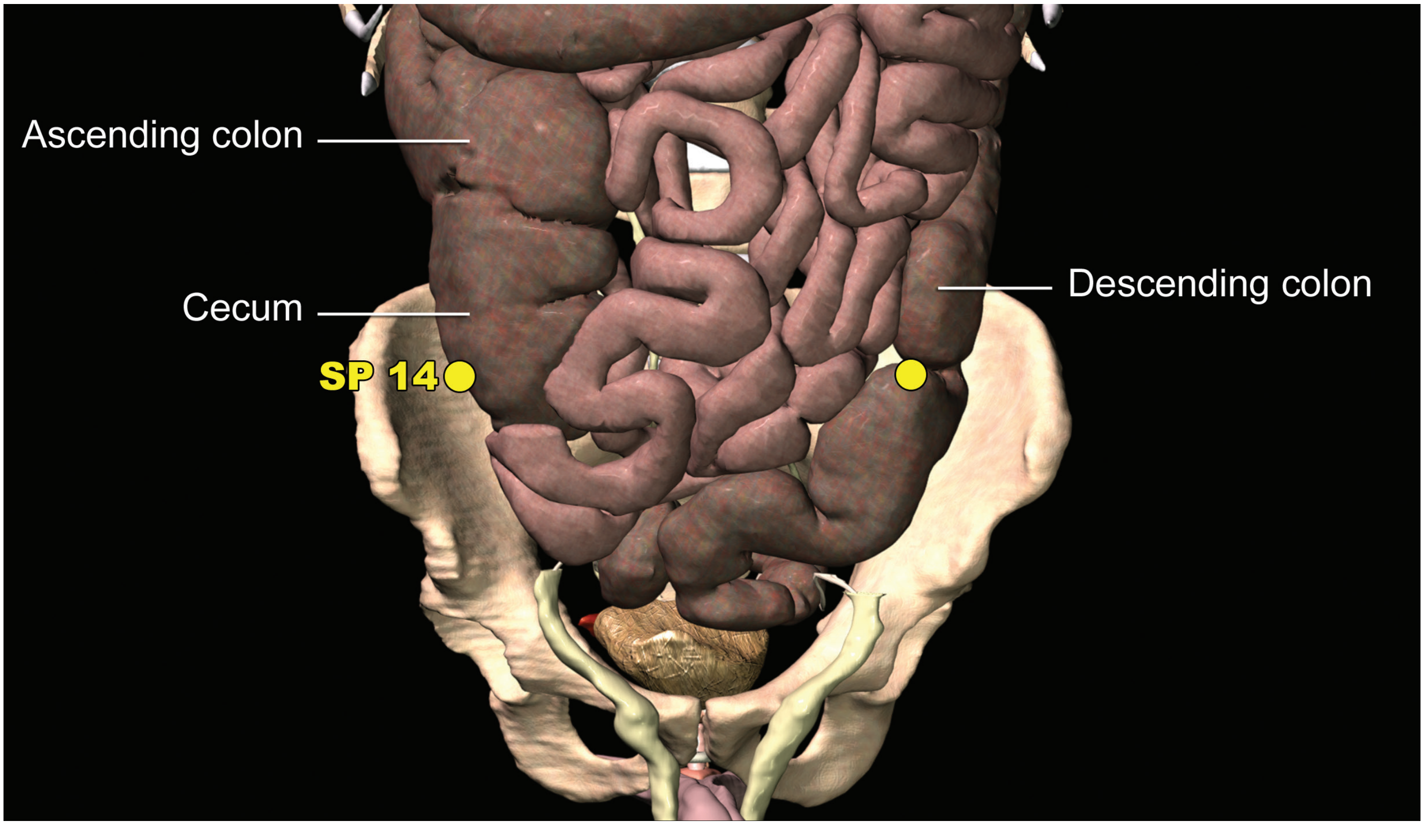

Figure 4-35. SP 14, "Abdominal Bind" or "Abdominal Knot" connotes the cramping, distending discomfort of sluggish colonic motility through structures visualized here, namely the cecum and descending colon.

acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

The SP channel on the abdomen along the linea semilunaris coincides with the most common site of thoracoabdominal nerve entrapment, as the nerve is changing direction to either enter a fibrous tunnel or is passing over either a fibrous or muscular band.[5] Vigorous exercise, traction, or other traumatic events or sources of compression may lead to localized swelling that compromises vascular supply to the nerve, worsening the irritation and neuropathic pain. The pain may cause diagnostic confusion, as it has both acute and chronic aspects and cause diffuse, referred, and/or localized discomfort. In women, the pain may seem to be coming from ovaries or bladder. Men may complain of a hernia or ulcer. Some may believe they have cancer or another "horrible" condition because of the diagnostic confusion and uncertainty they have developed around the condition. Abdominal wall pain that is incorrectly attributed to an intra-abdominal process may lead to unnecessary consultation, testing, and surgery, further complicating the problem and delaying proper diagnosis and care. Abdominal cutaneous nerve entrapment syndrome (ACNES) that radiates to the scrotum or vulva suggests entrapment of the T12/L1 nerve, although trigger point pathology from the adductor musculature should be ruled out, along with inguinal or femoral hernia. Pain may follow the nerves' obliquity, but urolithiasis may also produce the same directionality of pain but with far more severity. Other intra-abdominal pathology that can resemble ACNES includes appendicitis, ovarian dysfunction, cholecystitis (at the T8-9 level) or peptic ulcer disease (also at the T8-9 level). More cranial nerve entrapment can suggest costochondritis, slipping rib syndrome, pleuritis, or involvement of the cutaneous nerves at the levels of T6-T8. On physical examination, patients may point to the neuromuscular foramen along the SP line of the abdomen or claim "That's it" when the examiner palpates this site. Dorsal branches of the spinak nerves may become entrapped at the outer Bladder line and palpation over those exit sites is also warranted. Local treatment can involve needling, pressure, and heat applied to the entrapment sites in order to loosen tissue, deactivate trigger points, and relax the fascia.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. These venous connections provide a route for venous return from the lower extremities to bypass the inferior vena cava in cases of obstruction or ligation. Instead, they drain into the

SP 15

Da Heng "Great Horizontal"

On the lateral limit of the umbilical region, on the linea semilunaris, approximately 4 cun lateral to the umbilicus (CV 8).

Caution needling here. Deep needling may enter the ascending colon. See Figure 4-38.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: Rectus sheath hematoma can result from hemorrhage into the rectus muscle due to rupture of either the superior or inferior epigastric arteries or their branches, as well as a tear of the rectus abdominis muscle. Fascial strains may affect this region as well, caused by strenuous exercise or stretching, such as with yogic postures.[1] Rectus sheath hematoma may be more common in women on oral anticoagulants who strain during defecation or coughing.[2] Acupuncture and related techniques may lessen fascial restrictions, pain, inflammation, and myofascial dysfunction in tissues associated with the rectus sheath.

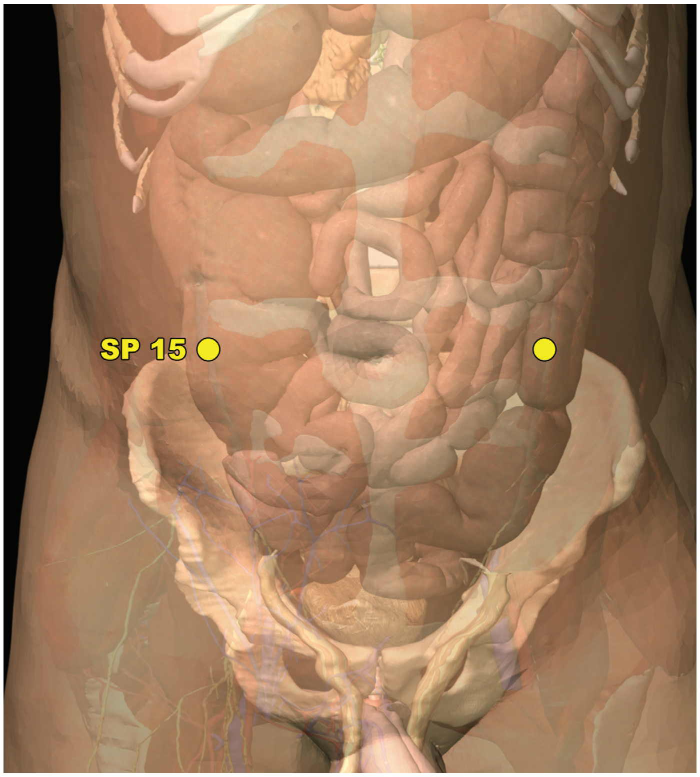

Figure 4-37. The name for SP 15, "Great Horizontal" indicates the point's location level with the umbilicus. Its indications for abdominal pain become evident based on the ascending and descending colon that share this cross section, shown in Figure 4-38.

Muscles

- **External oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis aponeurosis:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger point pathology in the abdominal oblique muscles such as at SP 15 may send referred pain in various directions across the abdomen, including toward the ipsilateral or contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia, leading to a variety of diagnostic enigmas and confusion.

Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence that have difficulty exercising the pelvic floor muscles.[3] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence.

Nerves

- **10th intercostal nerve:** Supplies the skin in this region.
- **1st lumbar nerve:** Contributes to nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves and L1):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: The iliohypogastric nerve, one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen, especially when the incision extends lateral to the inferior rectus abdominis muscle. Surgeries where this may happen include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Acupuncture and related techniques in the vicinity of abdominal SP points may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[4] Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

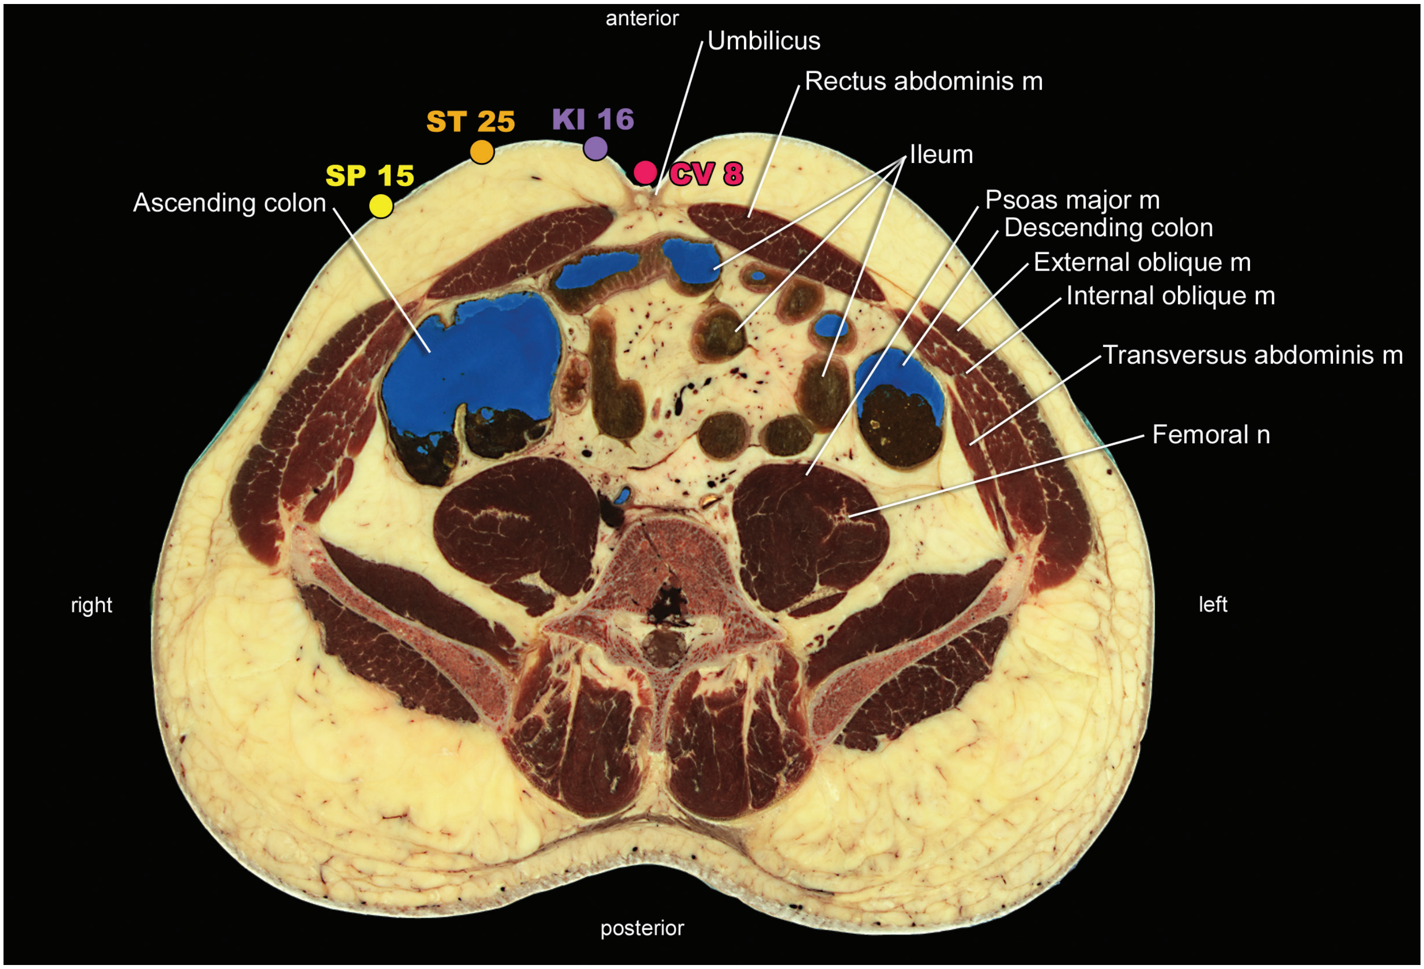

Figure 4-38. The abdomen bulges to create the "Great Horizontal", seen here in cross section.

The SP channel on the abdomen along the linea semilunaris coincides with the most common site of thoracoabdominal nerve entrapment, as the nerve is changing direction to either enter a fibrous tunnel or is passing over either a fibrous or muscular band.[5] Vigorous exercise, traction, or other traumatic events or sources of compression may lead to localized swelling that compromises vascular supply to the nerve, worsening the irritation and neuropathic pain. The pain may cause diagnostic confusion, as it has both acute and chronic aspects and cause diffuse, referred, and/or localized discomfort. SP 16

Fu Ai "Abdominal Lament"

On the upper abdomen, on the linea semilunaris, approximately 4 cun lateral to the anterior midline, level with CV 11, 3 cun proximal to SP 15. Because abdominal girths vary so dramatically between individuals, the most accurate manner of SP point location on the abdomen involves locating the linea semilunaris rather than counting cun.[1]

Caution needling here. Deep needling may enter the transverse colon, but the transversus abdominis muscle offers an extra layer of protection from needle entry into the intestine. See Figure 4-40.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: Rectus sheath hematoma can result from hemorrhage into the rectus muscle due to rupture of either the superior or inferior epigastric arteries or their branches, as well as a tear of the rectus abdominis muscle. Fascial strains may affect this region as well, caused by strenuous exercise or stretching, such as with yogic postures.[2] Rectus sheath hematoma may be more common in women on oral anticoagulants who strain during defecation or coughing.[3] Acupuncture and related techniques may lessen fascial restrictions, pain, inflammation, and myofascial dysfunction in tissues associated with the rectus sheath.

Muscles

- **External oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Internal oblique aponeurosis:** Flexes and rotates the trunk, as well as supports and compresses the abdominal organs.
- **Transversus abdominis aponeurosis:** Compresses and supports the abdominal organs; acts as an antagonist of the diaphragm to facilitate exhalation.

Clinical Relevance: Trigger point pathology in the abdominal oblique muscles such as at SP 15 may send referred pain in various directions across the abdomen, including toward the ipsilateral or contralateral subcostal margin, the umbilicus, the groin, and/or the genitalia, leading to a variety of diagnostic enigmas and confusion.

Some evidence exists that the transversus abdominis and pelvic floor muscles contract together. Activating the transversus abdominis may increase urethral pressure and aid women with urinary incontinence that have difficulty exercising the pelvic floor muscles.[4] Stimulation of local afferents with acupuncture and related techniques may aid in recovery of continence.

Nerves

- **7th through 9th intercostal nerve:** Supplies the skin in this region.
- **1st lumbar nerve:** Contributes to nerve supply of the internal oblique and transverse abdominal muscles.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves and L1):** Innervate the anterior abdominal

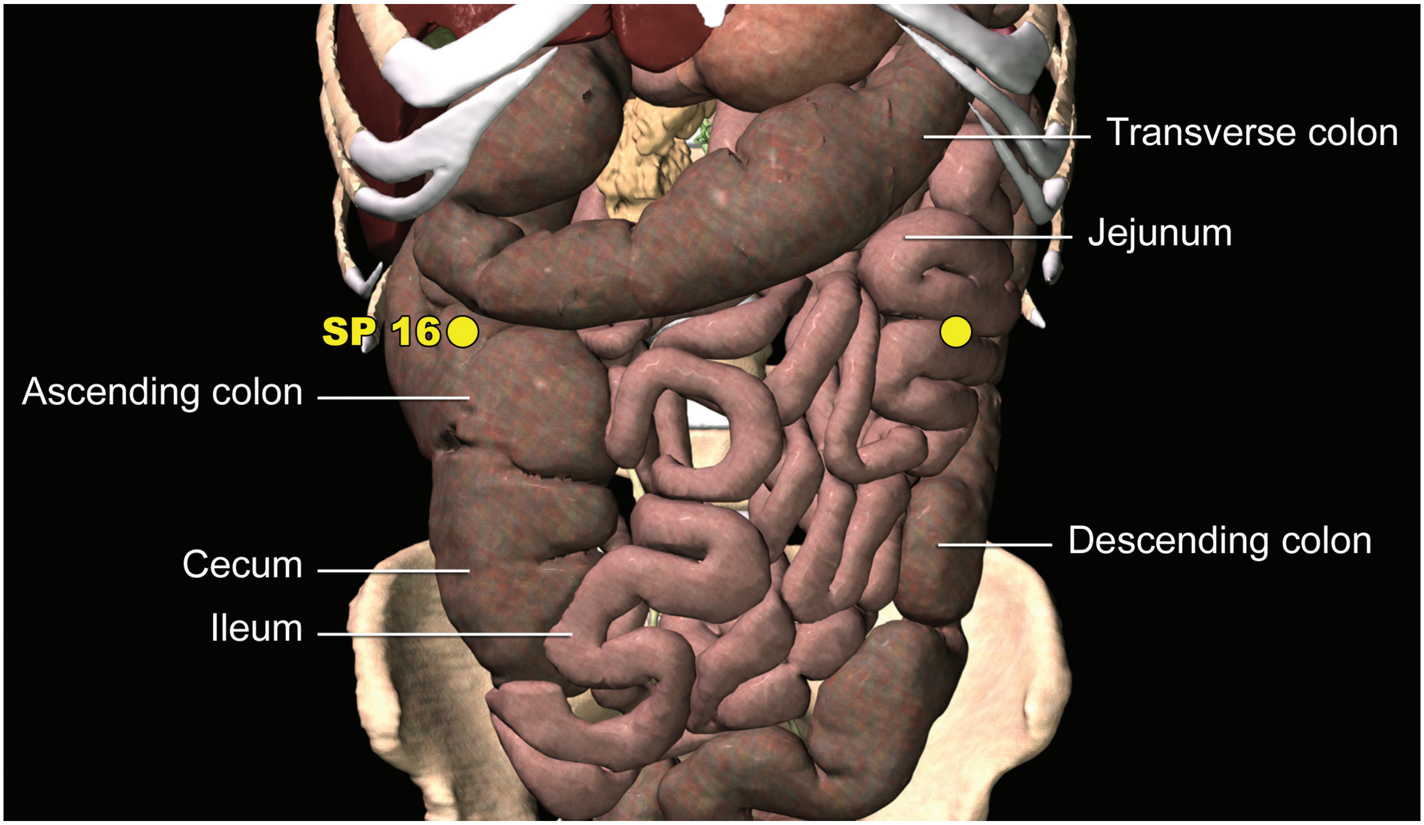

Figure 4-39. Abdominal Lament", SP 16, lands where a patient experiencing abdominal pain may double over.

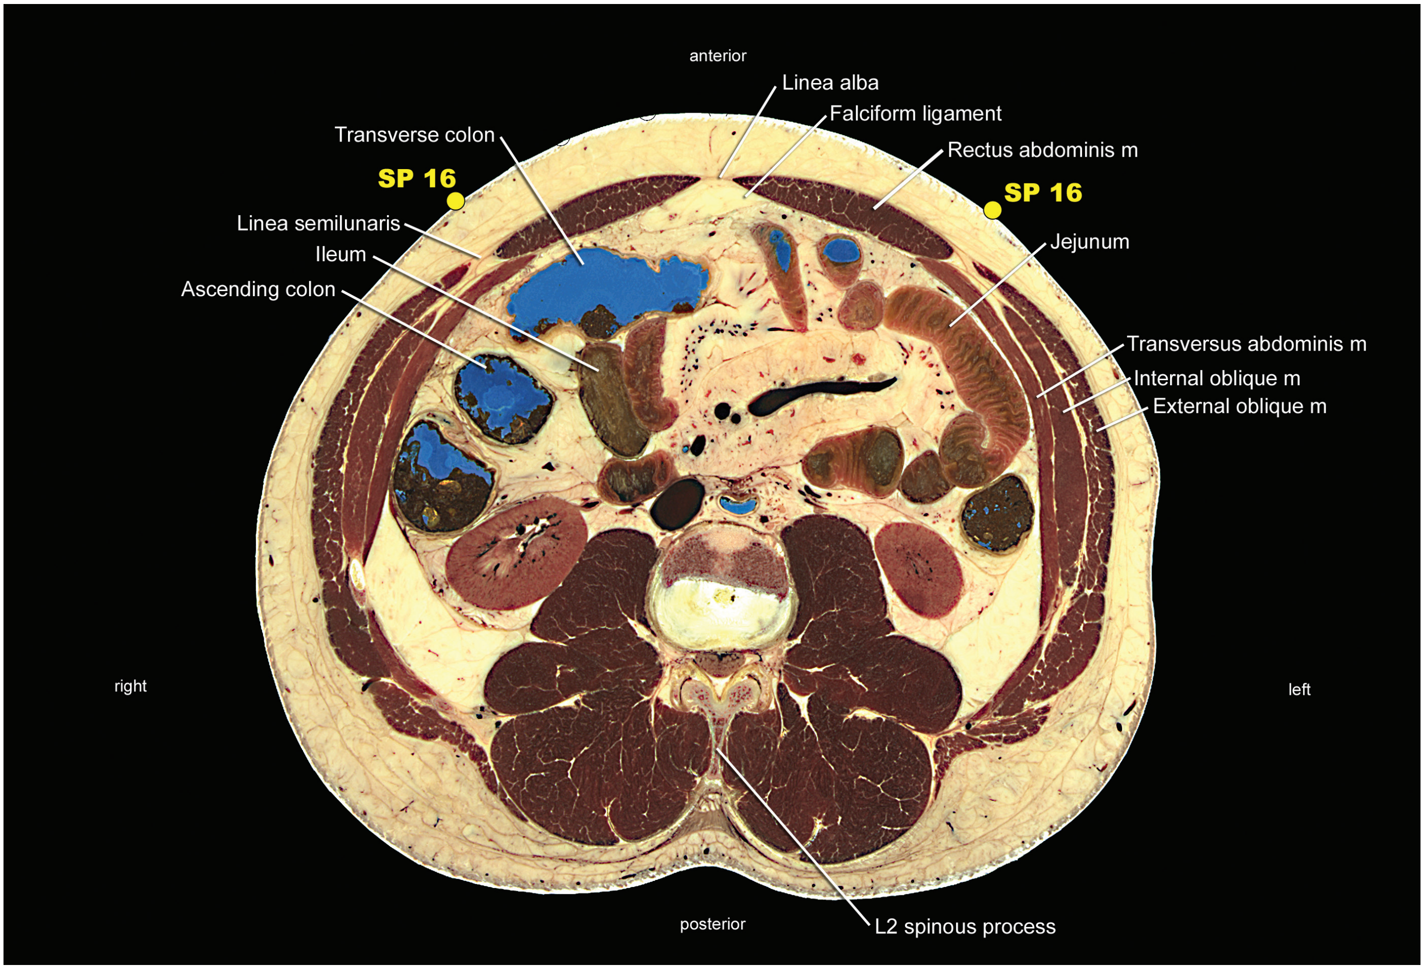

Figure 4-40. In this cross section at the level of SP 16, or "Abdominal Lament", the transverses abdominis muscle provides an additional layer of protection between the skin and the colon, although caution remains warranted.

muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: The iliohypogastric nerve, one of the more caudal thoracoabdominal nerves, is susceptible to injury from surgical procedures to the lower abdomen, especially when the incision extends lateral to the inferior rectus abdominis muscle. Surgeries where this may happen include hysterectomy, inguinal herniorrhaphy, and appendectomy. The nerves can be damaged when a suture passes around the nerve and it becomes bundled into the fascial repair. Scar tissue or neuroma formation can entrap the nerves postoperatively. Athletic injuries that traumatize or tear the lower abdominal muscles and fascia may similarly place traction on the nerve. Pregnancy can stretch the nerve as well. Acupuncture and related techniques in the vicinity of the abdominal SP points may improve nerve function, reduce pain, relieve tenderness to palpation, and benefit sensation.

Procedures that may injure the ilioinguinal nerve include Pfannenstiel incisions, incisions for iliac crest harvesting, appendectomy, inguinal herniorrhaphy, inguinal lymph node biopsy, femoral catheter placement, orchiectomy, total abdominal hysterectomy, and abdominoplasty.[5] Hockey players may tear the lower external oblique aponeurosis and injure the ilioinguinal nerve. Again, physical medicine approaches such as acupuncture may improve and normalize nerve function, which includes pain and tenderness with pressure where the nerve exits the inguinal canal as well as loss of sensation.

The SP channel on the abdomen along the linea semilunaris coincides with the most common site of thoracoabdominal nerve entrapment, as the nerve is changing direction to either enter a fibrous tunnel or is passing over either a fibrous or muscular band.[6] Vigorous exercise, traction, or other traumatic events or sources of compression may lead to localized swelling that compromises vascular supply to the nerve, worsening the irritation and neuropathic pain. The pain may cause diagnostic confusion, as it has both acute and chronic aspects and cause diffuse, referred, and/or localized discomfort. In women, the pain may seem to be coming from ovaries or bladder. Men may complain of a hernia or ulcer. Some may believe they have cancer or another "horrible" condition because of the diagnostic confusion and uncertainty they have developed around the condition. Abdominal wall pain that is incorrectly attributed to an intra-abdominal process may lead to unnecessary consultation, testing, and surgery, further complicating the problem and delaying proper diagnosis and care. Abdominal cutaneous nerve entrapment syndrome (ACNES) that radiates to the scrotum or vulva suggests entrapment of the T12/L1 nerve, although trigger point pathology from the adductor musculature should be ruled out, along with inguinal or femoral hernia. Pain may follow the nerves' obliquity, but urolithiasis may also produce the same directionality of pain but with far more severity. Other intra-abdominal pathology that can resemble ACNES includes appendicitis, ovarian dysfunction, cholecystitis (at the T8-9 level) or peptic ulcer disease (also at the T8-9 level). More cranial nerve entrapment can suggest costochondritis, slipping rib syndrome, pleuritis, or involvement of the cutaneous nerves at the levels of T6-T8. On physical examination, patients may point to the neuromuscular foramen along the SP line of the abdomen or claim, "That's it" when the examiner palpates this site. Dorsal branches of the spinal nerves may become entrapped at the outer Bladder line and palpation over those exit sites is also warranted. Local treatment can involve needling, pressure, and heat applied to the entrapment sites in order to loosen tissue, deactivate trigger points, and relax the fascia.

Vessels

- **Superficial epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.
- **Inferior epigastric artery:** Supplies the rectus abdominis and medial portion of the anterolateral abdominal wall.
- **Superficial epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.

Clinical Relevance: The various superficial venous channels that course over the abdomen provide alternative sources of vascular access if attempts at peripheral venipuncture fail for patients with portal hypertension due to liver cirrhosis or other causes. Accessing superficial vessels avoids the risks associated with pursuing central venous access.[7] Inferior vena caval obstruction (e.g., from thrombosis or tumor) or its congenital absence can cause the paraumbilical and abdominal subcutaneous veins to become patent.[8] The continued close relationship between the SP channel and underlying veins serves as a reminder of acupuncture's origins as a bloodletting procedure.

SP 17

Shi Dou "Food Hole"

On the lateral side of the chest, in the 5th intercostal space, 6 cun lateral to the anterior midline, level with CV 16.

Caution needling! The lung lies below this point. Puncture obliquely and laterally along the intercostal space. Do not needle deeply.

Muscles

- **Serratus anterior muscle:** Holds the scapula against the thoracic wall. Protracts and rotates the scapula.

Clinical Relevance: Trigger points in the serratus anterior muscle in the vicinity of SP 17 produce pain in the muscle itself on the lateral mid-thorax. It may also radiate along the PC and HT channels to the palmar aspect of the 4th and 5th fingers.

Nerves

- **5th intercostal nerve:** Supplies the skin and muscles in this region.
- **Long thoracic nerve (C5-C7):** Supplies the serratus anterior muscle. A pure motor nerve that only innervates the serratus anterior. The nerve descends on the lateral aspect of the thoracic cage, branching to supply each digitation of the serratus anterior muscle. This anchors it at regular and short intervals along its course, thereby limiting its ability to lengthen or glide as a result of extreme excursions of the shoulder girdle.[1]

Clinical Relevance: Long thoracic nerve dysfunction can cause serratus anterior dysfunction and lead to notalgia paresthetica,

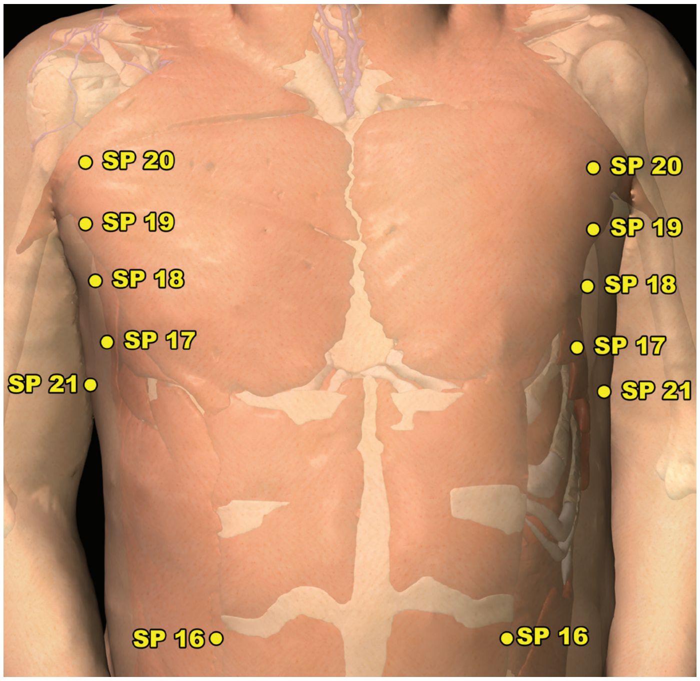

Figure 4-41. SP 17 through SP 21 occupy a seemingly unrelated region from the previous SP group on the abdomen. However, the drainage pathway that serves as a collateral route for abdominopelvic venous blood connects with this thoracoepigastric venous system, further characterized in yellow arrows in Figure 4-42.

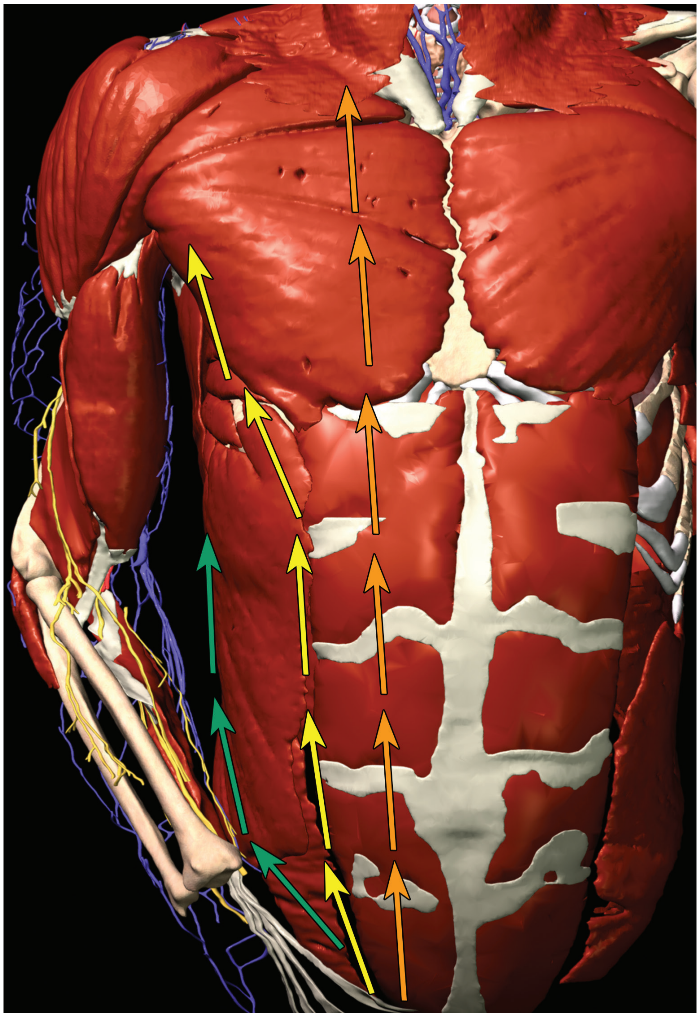

Figure 4-42. The vascular basis of the three channels traveling over the anterior abdominal wall relate closely to the collateral routes for drainage of abdominopelvic venous blood in the event that it cannot return to the heart as it normally would, through the inferior vena cava (IVC). As indicated here by the yellow arrows representing the SP line, backed up blood from the occluded IVC can reverse course through the valveless veins of the anterior abdominal wall and travel superficially through the superficial epigastric veins to the thoracoepigastric vein and ultimately the lateral thoracic vein, beneath SP 17 to SP 20. The orange arrows signify the ST channel and overlie the territory delineated by the anastomising inferior and superior epigastric veins. If these vascular pathways serve as collateral drainage routes, they empty into the internal thoracic veins of the superior vena caval system, sharing terrain with the KI channel. The blue-green arrows trace the lower abdominal trajectory of the LR line as it parallels the course of the superficial circumflex iliac veins which also anastomose in the subcutaneous tissues of the antero-lateral body wall with tributaries of the axillary vein. Finally, the thoracoepigastric veins in the vicinity of SP 21 become particularly prominent in cases of IVC obstruction. This helps explain why the early acupuncturists dubbed SP 21 as "The Great Connecting Point of All Connecting Point", viewing it as the major crossroad where several significant venous channels intersect.

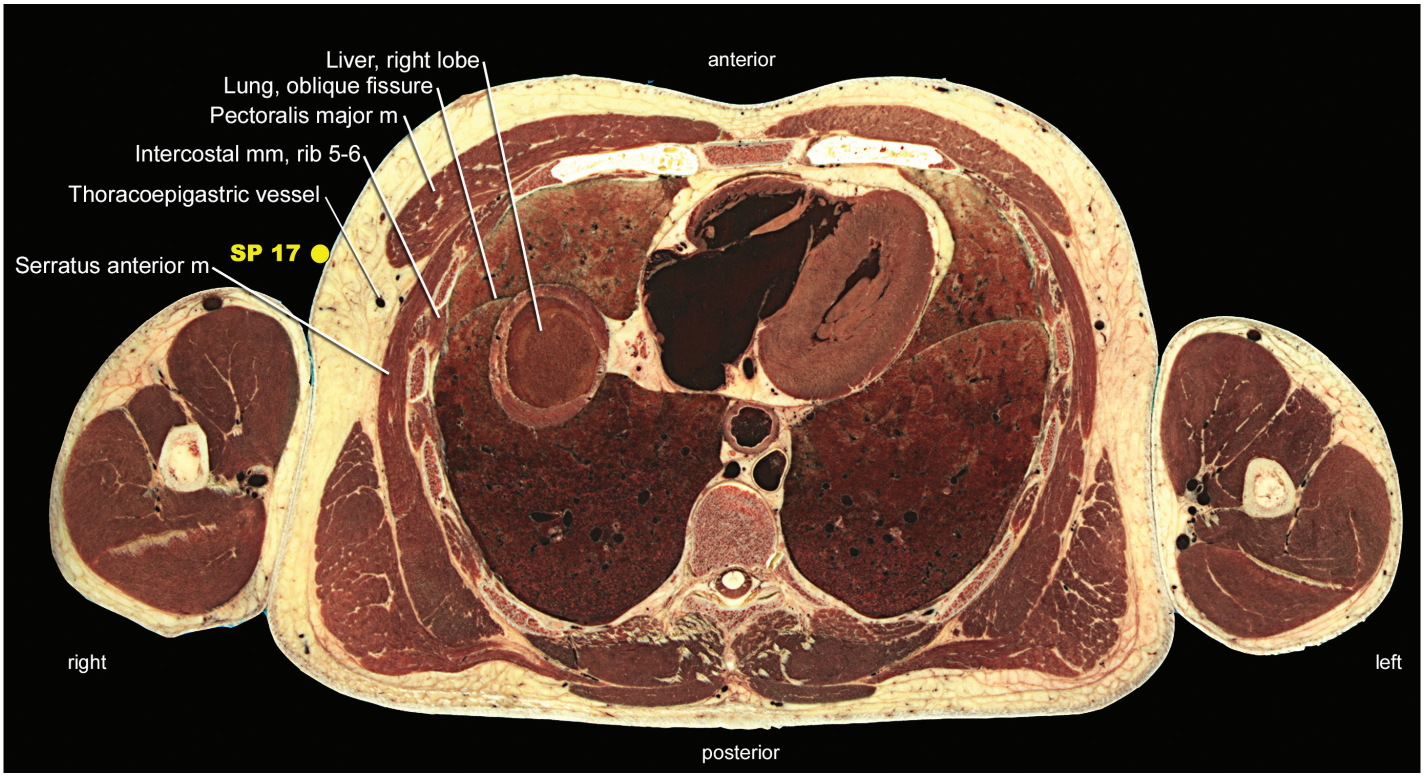

Figure 4-43. The descriptive name for SP 17, "Food Hole", may refer to the nearby nipple, associating the point with the feeding functions of the breast. The nipple in this image appears on the skin surface between the labels for the lung and liver.

a condition of pain with or without pruritus and paresthesia in the section between the spine and medial border of the scapula. Abnormal scapulothoracic stabilization may cause traction or compression of the cutaneous medial branches belonging to the dorsal primary rami of the thoracic spinal nerves.[2] Acupuncture, electroacupuncture, massage, laser therapy, or transcutaneous electrical nerve stimulation (TENS) may alleviate the discomfort rapidly and significantly. Causes of long thoracic nerve injury include sports injuries, heavy load bearing, traction injury, viral infection, vaccinations, and surgical procedures. More severe dysfunction causes scapulothoracic winging.[3]

Vessels

- **5th intercostal artery and vein:** Supplies and drains, respectively, the intercostal muscles, overlying skin, and parietal pleura.
- **Lateral thoracic artery:** Arises from the axillary artery. It descends along the axillary border of the pectoralis minor toward the thoracic wall.
- **Thoracoepigastric vein:** This vein arises from the region of the superficial epigastric vein and drains into the axillary vein or lateral thoracic vein. Provides a subcutaneous collateral pathway for the superficial circumflex iliac veins and the superficial epigastric veins to return abdominopelvic venous blood to the heart, as they anastomose with the lateral thoracic vein, a tributary of the axillary vein. Because these veins are valveless, blood can flow back into the axillary vein and bypass the inferior vena cava. The communication pathway between the lower veins and the lateral thoracic vein constitutes the thoracoepigastric vein.

Clinical Relevance: Mondor's disease, or phlebitis of the thoracoepigastric vein, was first described in 1939. This vascular rarity may be mistaken as a serious disease of the breast or body wall.[4] The painful and tender cordlike structures that follow from SP 17 to SP 20 are actually dilated segments of the thoracoepigastric vein. Although most cases are self-limiting, acupuncture, laser therapy, massage, or other forms of neuromodulation and physical medicine may facilitate recovery from this inflammatory and confusing condition. Although the condition is ordinarily benign, it may accompany or follow other conditions such as silicoadenitis of axillary nodes, breast cancer, and aesthetic mammaplasty.[5]

Indications and Potential Point Combinations

- **Back pain in the T5-T7 paraspinal region:** SP 17, GB 22, GB 23, BL 15.
- **Intercostal neuralgia in the 5th intercostal space region:** SP 17, BL 15, BL 14, GB 22, GB 23.
- **Hiccough:** SP 17, CV 22, CV 14.

SP 18

Tian Xi "Celestial Stream"

On the lateral side of the pectoral region, in the 4th intercostal space, 6 cun lateral to the anterior midline, level with CV 17.

Point placement appears in Figure 4-41.

Muscles

- **Serratus anterior muscle:** Holds the scapula against the thoracic wall. Protracts and rotates the scapula.

Clinical Relevance: Trigger points in the serratus anterior muscle in the vicinity of SP 18 produce pain in the muscle itself on the lateral mid-thorax. It may also radiate along the PC and HT channels to the palmar aspect of the 4th and 5th fingers.

Nerves

- **4th intercostal nerve:** Supplies the skin and muscles in this region.
- **Long thoracic nerve (C5-C7):** Supplies the serratus anterior muscle. A pure motor nerve that only innervates the serratus anterior. The nerve descends on the lateral aspect of the thoracic cage, branching to supply each digitation of the serratus anterior muscle. This anchors it at regular and short intervals along its course, thereby limiting its ability to lengthen or glide as a result of extreme excursions of the shoulder girdle.[1]

Clinical Relevance: Long thoracic nerve dysfunction can cause serratus anterior dysfunction and lead to notalgia paresthetica, a condition of pain with or without pruritus and paresthesia in the section between the spine and medial border of the scapula. Abnormal scapulothoracic stabilization may cause traction or compression of the cutaneous medial branches belonging to the dorsal primary rami of the thoracic spinal nerves.[2] Acupuncture, electroacupuncture, massage, laser therapy, or transcutaneous electrical nerve stimulation (TENS) may alleviate the discomfort rapidly and significantly. Causes of long thoracic nerve injury include sports injuries, heavy load bearing, traction injury, viral infection, vaccinations, and surgical procedures. More severe dysfunction causes scapulothoracic winging.[3]

Vessels

- **4th intercostal artery and vein:** Supplies and drains, respectively, the intercostal muscles, overlying skin, and parietal pleura.
- **Lateral thoracic artery:** Arises from the axillary artery. It descends along the axillary border of the pectoralis minor toward the thoracic wall.
- **Lateral thoracic vein:** A tributary of the axillary vein, the lateral thoracic vein communicates with the superficial epigastric and superficial circumflex iliac veins to provide collateral routes for abdominopelvic venous blood return.
- **Thoracoacromial artery:** A branch of the axillary artery, the thoracoacromial artery divides into four branches (acromial, deltoid, pectoral, and clavicular). The pectoral branch supplies this region.
- **Thoracoepigastric vein:** This vein arises from the region of the superficial epigastric vein and drains into the axillary vein or lateral thoracic vein. Provides a subcutaneous collateral

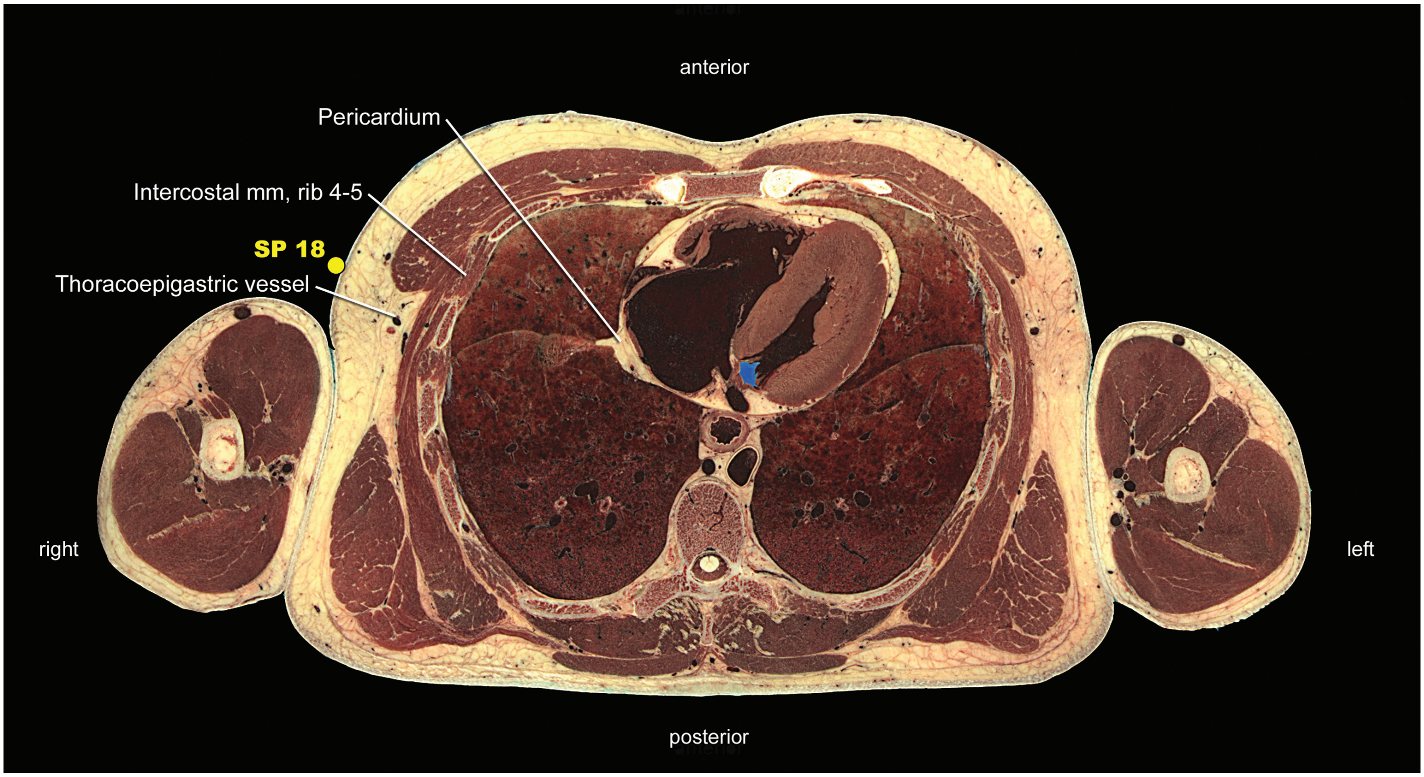

Figure 4-44. The "Celestial Stream", or "Celestial Ravine" affiliated with SP 18 refers to the thoracoepigastric vein lateral to the breast. The stream conveys blood through the channel (stream) over the chest (considered a "celestial" portion of the trunk as compared to the lower, more "earthy" regions below).

pathway for the superficial circumflex iliac veins and the superficial epigastric veins to return abdominopelvic venous blood to the heart, as they anastomose with the lateral thoracic vein, a tributary of the axillary vein. Because these veins are valveless, blood can flow back into the axillary vein and bypass the inferior vena cava. The communication pathway between the lower veins and the lateral thoracic vein constitutes the thoracoepigastric vein.

Clinical Relevance: Mondor's disease, or phlebitis of the thoracoepigastric vein, was first described in 1939. This vascular rarity may be mistaken as a serious disease of the breast or body wall.[4] The painful and tender cordlike structures that follow from SP 17 to SP 20 are actually dilated segments of the thoracoepigastric vein. SP 20

Zhou Rong "Encircling Glory" or "All-Round Flourishing"

On the lateral side of the pectoral region, in the 2nd intercostal space, 6 cun lateral to the anterior midline, approximately one intercostal space below LU 1.

Point placement appears in relation to SP 17, SP 18, and SP 19 in Figure 4-41.

Muscles

- **Pectoralis major muscle:** A powerful adductor of the arm. Rotates the humerus in a medial direction.
- **Pectoralis minor muscle:** Stabilizes the scapula by holding it anteriorly against the thoracic wall and by drawing it inferiorly.
- **Coracobrachialis muscle:** Moves the humerus forward and in a medial direction, resulting in shoulder flexion and adduction.

Clinical Relevance: Trigger points in the pectoralis major muscle may refer to the shoulder, arm, or breast, depending on their location. In the clavicular section, referred pain extends to the shoulder and anterior deltoid region. Figure 4-46 depicts the intimate relationship between these two muscle groups. Trigger points on the lateral margin of the pectoralis major refer strongly to the breast and may travel to the axilla, causing the patient concern about breast pathology. The cross section of Figure 4-46 illustrates the anatomy relevant to SP 20 in a man; overlying subcutaneous and mammary tissue will likely increase the distance between SP 20 and the pectoralis major muscle. Trigger points in the pectoralis minor muscle overlap with that of its major counterpart. In addition, referred pain follows the PC line to the palmar middle and ring fingers.

Coracobrachialis trigger points at and around SP 20 refer strongly to the middle deltoid region and extend along the dorsal brachium, antebrachium, and hand, tipping off at the middle finger. The referred pain pattern closely resembles the TH line from TH 14 to TH 3.

Nerves

- **2nd intercostal nerve:** Supplies the skin and muscles in this region.
- **Medial pectoral nerve: (C7, C8, T1):** Supplies both the pectoralis minor and major muscles.

Figure 4-46. SP 20, called "Encircling Glory" or "All-Round Flourishing" fits the multifaceted anatomy contained within this cross section. It also reveals the proximity of SP 20 to the pectoralis major, the anterior deltoid which it abuts, and the pectoralis minor muscle. The latter appears here as the darker, crescent-shaped structure deep to the massive pectoralis major that spans the entire chest.
The blood coursing through the major vessels at this level nourish the entire body to allow it flourish, suggesting an explanation for the name of "All-Round Flourishing". On another level, "Encircling Glory" as well as "All-Round Flourishing" applies to the influence of the nerves and vessels along this section of the SP channel for breast health, with the term "glory" connoting the apex of the SP channel at SP 20 before it changes course and descending toward SP 21.

- **Lateral pectoral nerve (C5-C7):** Supplies the pectoralis major muscle.
- **Musculocutaneous nerve (C5-C7)**: Supplies the coracobrachialis muscle.

Clinical Relevance: Nerve damage after surgery, irradiation, or other procedures near the breast and SP 20 may damage local nerves and their supporting structures. This has the potential to induce chronic breast pain.[1] Intercostal neuromas following breast surgery may affect one or more intercostal nerves along the lateral chest wall. Acupuncture, massage, and related techniques may aid in reducing nerve-based pain and myofascial restriction contributing to the problem.

Vessels

- **2nd intercostal artery and vein:** Supplies and drains, respectively, the intercostal muscles, overlying skin, and parietal pleura.
- **Lateral thoracic artery:** Arises from the axillary artery. It descends along the axillary border of the pectoralis minor toward the thoracic wall.
- **Lateral thoracic vein:** A tributary of the axillary vein, the lateral thoracic vein communicates with the superficial epigastric and superficial circumflex iliac veins to provide collateral routes for abdominopelvic venous blood return.
- **Thoracoacromial artery:** A branch of the axillary artery, the thoracoacromial artery divides into four branches (acromial, deltoid, pectoral, and clavicular). The pectoral branch supplies this region.
- **Thoracoepigastric vein:** This vein arises from the region of the superficial epigastric vein and drains into the axillary vein or lateral thoracic vein. Provides a subcutaneous collateral pathway for the superficial circumflex iliac veins and the superficial epigastric veins to return abdominopelvic venous blood to the heart, as they anastomose with the lateral thoracic vein, a tributary of the axillary vein. Because these veins are valveless, blood can flow back into the axillary vein and bypass the inferior vena cava. The communication pathway between the lower veins and the lateral thoracic vein constitutes the thoracoepigastric vein.

Clinical Relevance: Mondor's disease, or phlebitis of the thoracoepigastric vein, was first described in 1939. This vascular rarity may be mistaken as a serious disease of the breast or body wall.[2] The painful and tender cordlike structures that follow from SP 17 to SP 20 are actually dilated segments of the thoracoepigastric vein. Although most cases are self-limiting, acupuncture, laser therapy, massage, or other forms of neuromodulation and physical medicine may facilitate recovery from this inflammatory and confusing condition. Although the condition is ordinarily benign, it may accompany or follow other conditions such as silicoadenitis of axillary nodes, breast cancer, and aesthetic mammaplasty.

Indications and Potential Point Combinations

- **Fullness and pain in chest and lateral thorax:** SP 20, GB 22, GB 23, SP 21.
- **Rib pain, intercostal neuralgia:** SP 20, local trigger points, BL 12, BL 13.
- **Esophageal spasm or pain:** SP 20, PC 6, CV 22, CV 14
- **Hiccoughs:** SP 20, BL 17, CV 12.
- **Cough and chest congestion:** SP 20, LU 7, LI 4, LI 11, BL 12, BL 13, CV 22.

SP 21

Da Bao "Great Wrapping"

On the lateral chest wall, on the midaxillary line, 6 cun below the end of the anterior axillary crease, approximately midway between the axilla and the end of the 11th rib. Palpate this area to identify the most tender location. This may fall at either the 6th or 7th intercostal space. Depending on point location based on tenderness to palpation, SP 21 may be found atop the external oblique muscle as in Figure 4-48 or closer to the serratus anterior or latissimus dorsi.

Muscles

- **Abdominal external oblique muscle:** Pulls the chest downward and raises intraabdominal pressure by compressing the abdominal cavity. Assists in flexing and rotating the spine. Can laterally flex the spine.

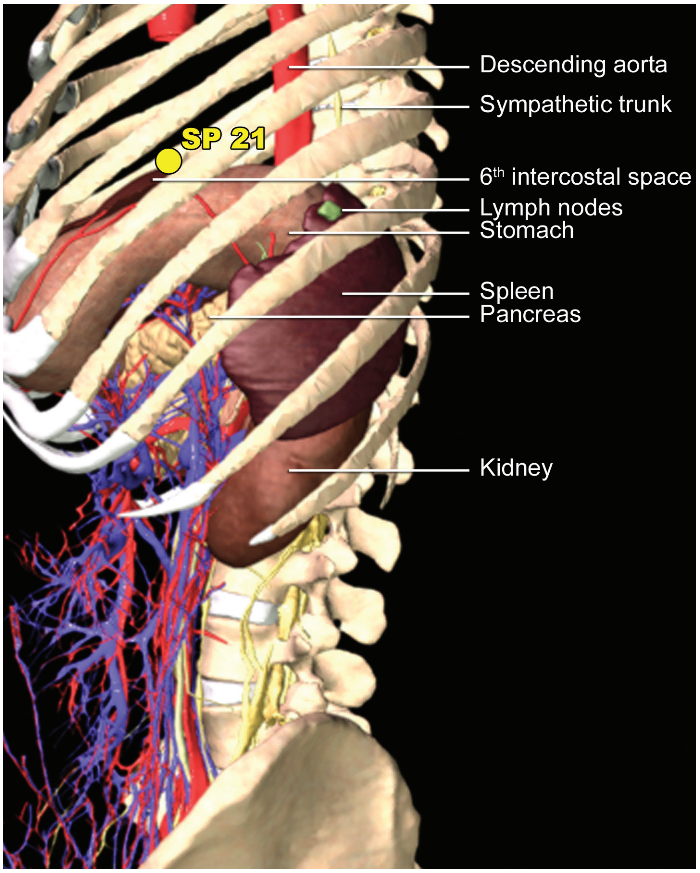

Figure 4-47. This depiction reveals the association of SP 21 to the spleen, pancreas, stomach, and kidney. In cases of portal vein hypertension, the vascular system develops a porto-caval collateral system of venous return.[2] Common causes of portal hypertension include posthepatic and alcoholic cirrhosis. Connecting the portal system with systemic circulation as a result of the vasculature responding to high portal pressure changes the conditions within existing vessel junctions as well as creates new vessels by means of angiogenesis. This collateral route for venous blood to return to the heart reduces portal pressure but also loads cardiac muscle and allows intestinal toxins to enter the general circulation. Splenorenal shunts may develop, perceived as a palpable, hard, non-pulsatile mass in the upper left quadrant of the abdomen, with or without splenomegaly. This left lateral view of SP 21 illustrates where such a connection between the splenic and renal veins may occur.

Clinical Relevance: External oblique trigger points may serve as a source of lateral truncal discomfort and, occasionally, digestive disturbances. Note how SP 21 sits between the serratus anterior and latissimus dorsi muscles as depicted in the cross section, Figure 4-48. Acupuncture needling, acupressure, or laser therapy may address myofascial dysfunction at the borders of these muscles as well as the body of the external oblique. This area is often tender to pressure.

Note: SP 17 to SP 20 also relate to the external intercostal muscles. However, they are not listed as needling targets due to concerns of inadvertent puncture of the lung with chest wall penetration.

Nerves

- **6th intercostal nerve:** Supplies the skin and intercostal muscles in this region.
- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves and L1):** Innervate the anterior abdominal muscles, overlying skin, and the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior to the umbilicus.

Clinical Relevance: Nerve entrapment in this region from trauma, sports injuries, or surgical procedures may cause abdominal wall pain or a perception of internal organ dysfunction due to crosstalk between the somatic and visceral nerves within overlapping levels of the spinal cord.

Vessels

- **Sixth intercostal artery and vein:** Supplies and drains, respectively, the intercostal muscles, overlying skin, and parietal pleura.
- **Thoracoepigastric vein:** This vein arises from the region of the superficial epigastric vein and drains into the axillary vein or lateral thoracic vein. Provides a subcutaneous collateral pathway for the superficial circumflex iliac veins and the superficial epigastric veins to return abdominopelvic venous blood to the heart, as they anastomose with the lateral thoracic vein, which is a tributary of the axillary vein. Because these veins are valveless, blood can flow back into the axillary vein and bypass the inferior vena cava. The communication pathway between the lower veins and the lateral thoracic vein constitutes the thoracoepigastric vein.

Clinical Relevance: As illustrated in Figure 4-48, the thoracoepigastric vessels relate to the SP line here at its endpoint as well as elsewhere along the channel's course. Surgical approaches to the thorax or breast may interfere with circulation pathways. Acupuncture and related techniques may improve circulation, alleviate pain, and aid in restoring tissue health.

Indications and Potential Point Combinations

- **Respiratory problems: cough, asthma, dyspnea:** SP 21, LU 7, LU 5, LU 1, BL 13, GB 21.

Figure 4-48. This final point on the SP line, SP 21, touches the same cross sectional level occupied by the spleen organ. Its name, "Great Embracement", may refer to the external oblique muscle wrapping around the abdomen at this level. Chinese medicine metaphors named SP 21 "the connecting point of all connecting points", the "regulator of all the network channels", and the "irrigator of the five viscera t hat presides over yin and yang". These references implicate the function of local collateral vessels' balancing capacity via the oscillatory venous web that embraces the anterolateral abdominal wall.

- **Thoracic or chest wall pain, especially lateral costal region:** SP 21, GB 22, GB 23, CV 17, CV 20, BL 15.
- **Mondor's disease (obliterative phlebitis typically affecting the lateral thoracic, thoracoepigastric, or superior epigastric veins and their tributaries):**[1] SP 21, LU 2, SP 16, SP 9, SP 6, CV 12.
- **Superficial thrombophlebitis of the lateral thorax, (non-infectious only):** SP 21.

Channel 5:: The Heart (HT)

The Heart channel begins in the center of the axilla at HT 1. The channel descends along the medial brachium to the medial end of the cubital crease, at the elbow. From here, the Heart channel crosses the ventral aspect of the antebrachium to the ulnar side of the wrist over the ulnar artery. Crossing the palm between the 4th and 5th metacarpals, the Heart channel ends on the radial aspect of the dorsal tip of the little finger at HT 9.

The red highlighted region depicts the course of the T1-T2 dermatome. Spinal cord stimulation of the T1-2 segments of the cord normalizes the function in the the heart's intrinsic nervous system. Benefits include analgesia, reduced medication requirements, and fewer, less severe anginal episodes. Pain radiating down the arm secondary to myocardial ischemia emulates the Heart channel trajectory; this occurs due to the sharing of information between visceral and somatic afferent fibers within overlapping spinal cord segments. This causes the confusion about the origin of pain due to the higher density of sensory nerves in the skin than the heart.[1] Acupuncture, as well, benefits patients with angina. Specifically, neuromodulation with acupuncture provides a significant reduction in the number of angina attacks during treatment, significantly increased maximal workload capacity until onset of chest pain, and reduction in ST segment depression at maximal workload. Quality of life likewise significantly improved, as did parameters assessing physical performance, peripheral chilliness, pessimism, vertigo, and relaxation.[2]

HT 1

Ji Quan "Summit Spring" or "Highest Spring"

In the center of the axilla, medial or posterior to the pulsation of the axillary artery. Locate the point with the arm abducted. The point lies between the subscapularis muscle and the pectoralis minor, at the highest point of the axilla. (See Figure 5-4 to explore these relationships further.)

Caution: Avoid puncturing the axillary artery or vein. Avoid entering the thoracic cavity.

Muscles

- **Latissimus dorsi tendon:** Rotates the humerus medially. Extends and adducts the humerus. Raises the body toward the arm as when an individual climbs using the arms.
- **Teres major muscle:** Adducts the arm and rotates it medially.

Nerves

- **Brachial Plexus (C5-C8, T1):** A network of nerves, formed by the ventral rami of cervicothoracic spinal nerves, that supplies the neck, axilla, arm, and hand with motor, sensory, and autonomic nerve fibers. Exceptions include structures such as the trapezius muscle supplied by the accessory nerve and the floor of the axilla supplied by the intercostobrachia nerve (see below).
- **Medial brachial cutaneous nerve (C8, T1):** Supplies the skin on the medial brachium (arm).
- **Ulnar nerve (C8-T1):** Arises as a terminal branch of the medial cord of the brachial plexus, receiving fibers from C8, T1, and often C7.
- **Intercostobrachial nerve (T2):** The ventral ramus of the 2nd thoracic spinal nerve divides into branches, the 2nd intercostal nerve (which is the larger of the two) and a smaller branch, the intercostobrachial nerve. The intercostobrachial nerve is a lateral cutaneous branch of the 2nd intercostal nerve. It emerges from the 2nd intercostal space at the midaxillary line and penetrates the serratus anterior muscle to enter the brachial region (i.e., the axilla and arm). It innervates the floor of the axilla (i.e., the skin and its underlying subcutaneous tissue). The intercostobrachial nerve then communicates with the medial brachial cutaneous nerve to supply the dorsal and medial aspects of the brachium. It communicates with the posterior brachial cutaneous branch of the radial nerve.

Clinical Relevance: The biggest significance of HT 1 neurologically is its close proximity to the brachial plexus. As such, acupuncture, massage, and laser therapy to HT 1 often becomes the first step in the treatment of brachial plexopathy of non-neoplastic origin and acute brachial plexus neuritis. It also benefits patients with radiculopathy from cervical nerve root impingement due to spondylosis.[3]

Communications between the intercostal nerves (specifically, the second and third) and arms that supply the brachium are sources of referred cardiac pain.

Axillary node clearance for conditions such as breast cancer can damage the intercostobrachial nerve and thus impair sensation and/or cause neuropathic pain.[4] Acupuncture and related techniques aids the nerve in recovery and allot the patient to regain sensation. HT 1 would be implicated in an acupuncture needling protocol for this purpose.

Vessels

- **Circumflex scapular artery:** Arises from the subscapular artery and reaches the muscles on the dorsum of the scapula after curving around the axillary border of the scapula. The circumflex scapular artery takes part in the scapular anastomoses, along with several other vessels. The anastomoses occur on both the anterior and posterior surfaces. Participating vessels include the dorsal scapular, subscapular (via the circumflex scapular), and suprascapular arteries. These anastomoses create a potential collateral circulation pathway for the arm in the event of axillary

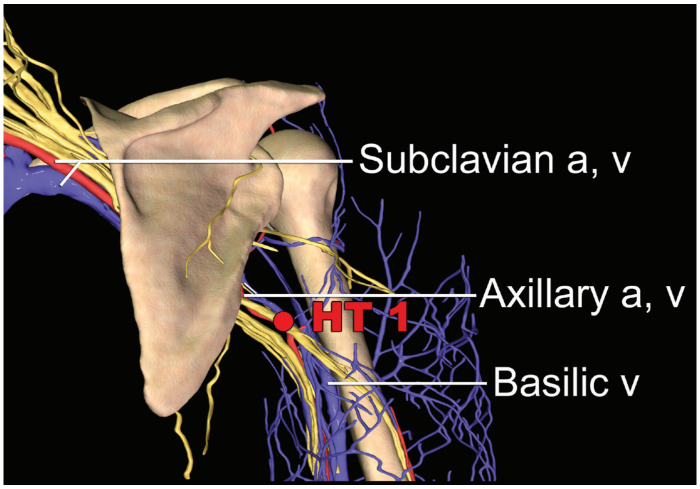

Figure 5-1. The name "Summit Spring" or "Highest Spring" for HT 1 connotes the axilla as the highest palpable location of the main artery (axillary artery) supplying the arm. Note that the axillary vein traveling through this region can become thrombosed and taught in cases of Mondor's Disease, causing them to bulge and grow taut, manifested as a "bowstring sign".

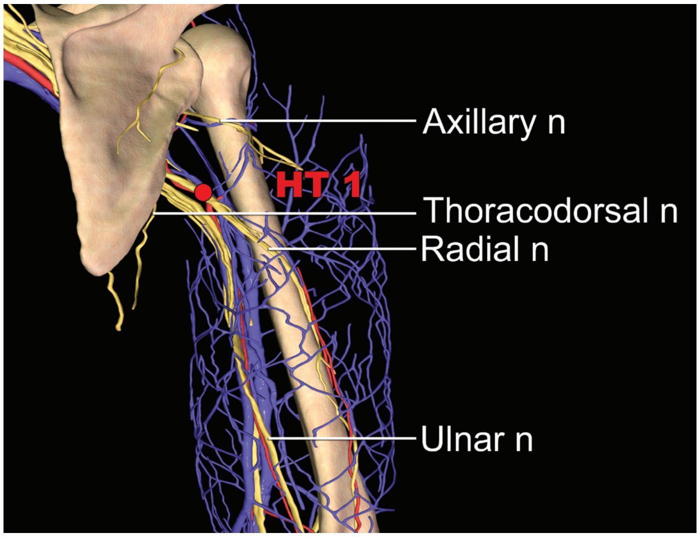

Figure 5-2. Neurologic indications for HT 1 brachial plexopathy; radial, ulnar, or median nerve injury; thoracic limb spasticity from stroke; and pain related to nerve compression or entrapment.

artery obstruction or ligation.

- **Axillary artery:** Provides blood flow to the arm. Arises from the subclavian artery. The third part of the axillary artery falls between the lateral border of the pectoralis minor muscle and the inferior border of the teres major muscle. Branches of the third portion of the axillary artery include the anterior and posterior circumflex humeral arteries and the subscapular artery.
- **Axillary vein:** The brachial veins that accompany the brachial artery unite with the basilic to form the axillary vein. The axillary vein ends lateral to the 1st rib and becomes the subclavian vein. The axillary vein connects, either directly or indirectly, with the inguinal region via the lateral thoracic vein and thoracoepigastric vein(s). The lateral thoracic vein is a tributary of the axillary vein and the thoracoepigastric veins arise from the anastomoses of superficial veins draining the groin. This connection between veins of the groin and the axillary vein creates a collateral channel through which venous blood returns to the heart in cases of inferior vena caval obstruction.
- **Basilic vein:** The basilic vein arises from the ulnar portion of the dorsal venous network of the hand and courses along the ulnar aspect of the forearm. It continues its ascent along the medial portion of the inferior arm (brachium), enters the axilla, and merges with the veins that accompany the brachial artery, thereby forming the axillary vein.

Clinical Relevance: Veins in the axillar outnumber arteries and commonly exhibit variations.[5] Arteritis in the head and arm could benefit from acupuncture and related techniques applied to highly vascularized regions such as HT 1, ST 9, and LU 9.[6]

Thrombophlebitis of the thoracoepigastric system of veins, also known as "Mondor's disease", affects women following breast cancer surgery with excision of the left axillary lymph nodes. It also occurs in women after breast augmentation of reactive hyperplasia of the axillary lymph nodes, misdiagnosed as silicoadenitis, leads to axillary node excision. Although Mondor's Disease most commonly appears below or on the lateral aspect of the breast (from SP 17 to SP 20), it also affects veins in the axilla.

When Mondor's disease affects the axillary vein, it causes them to exhibit a "bowstring sign" crossing the axilla from HT 1 toward HT 2. Superficial vein transection leads to blood stasis and phlebothrombosis when unidirectional valves disallow retrograde flow.[7] Mondor's disease is becoming more common as the number of breast augmentation mammoplasties and cancer surgeries increases. Acupuncture and related techniques aid in reducing pain and improving circulation in the region, though this should not replace specialist consultation as indicated.

Indications and Potential Point Combinations

- **Pains in ribs, arms, and pectoral area:** HT 1, plus palpate for trigger points in surrounding regions; e.g., subscapularis, pectoralis minor and major, teres minor and major, and intercostal muscles.
- **Thoracic limb paresthesias, paresis, or paralysis:** HT 1, plus points along neural pathways affected by the nerve injury; e.g., LI points for radial nerve dysfunction, HT and SI points for ulnar nerve dysfunction. Palpate for myofascial restrictions in the axillary and shoulder region that are perpetuating the neural impairment(s).

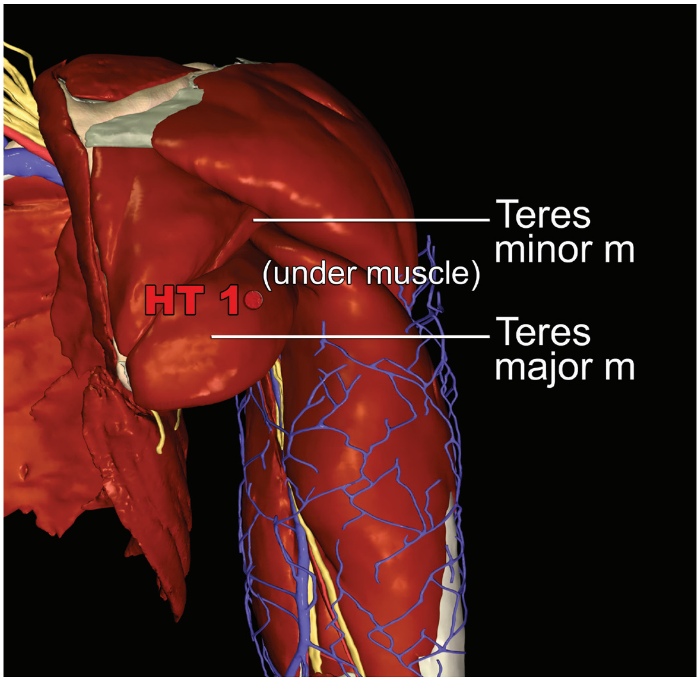

Figure 5-3. This image reveals the relationship of HT 1 deep to the teres muscles.

- **Brachial plexus injury:** HT 1; plus acupuncture points that impact the nerves affected by the injury. Target spinal nerve points on the lateral cervical region, GV 14, BL 11 as well as distal points related to the involved nerves.
- **Hot flushes, insomnia, night sweats, excessive thirst, dry mouth and throat:** HT 1, plus autonomic regulating points, such as LR 3, ST 36, LI 4.
- **Sadness, depression, anxiety:** HT 1, plus HT 3, LI 4, ST 36, LU 7.
- **Lactation disorders:** HT 1, SP 18, ST 18
- **Cardiac pain:** (After appropriate diagnostic and therapeutic measures have been taken for any cardiac irregularities) HT 1, or PC 6, CV 17, CV 14, CV 15, ST 36. Electrical stimulation applied to spinal cord segments C1-C2 (for vagal stimulation) and T1-T4 (to affect the intrathoracic intrinsic cardiac nervous system) utilizing points such as BL 10, BL 11, BL 12, BL 13, and BL 14 provides pain relief for patients suffering from severe angina pectoris.[1] The pain from cardiac disease usually refers to proximal somatic structures rather than distal ones; furthermore, nociceptive input from somatic and cardiac neurons converges onto the spinothalamic tract at T1-T5 but not C7 and C8. Thus, the neuroanatomic relationships would suggest selecting HT points along the T1 dermatome on the thoracic limb correspond to HT 1, HT 2, and HT 3, over more distal HT points. PC 6 falls within the T1 dermatome.[2]

HT 2

Qing Ling "Cyan Spirit" ("Blue Death")

On the medial side of the brachium, on the medial bicipital groove, 3 cun proximal to the cubital crease, on the line connecting HT 1 and HT 3.

Caution: The insertion site is directly over the brachial artery and companion veins. Avoid injuring the vessels; some suggest employing non-needling techniques to stimulate this site.

Fascia

- **Medial intermuscular septum:** Extends from the deep surface of the brachial fascia to the medial supracondylar ridge of the humerus. Divides the arm into anterior and posterior, or dorsal and ventral, compartments.
- **"Canal" or "Arcade" of Struthers (not always present):** A band or thickening of the deep, investing fascia in the distal third of the arm along the HT channel, at about the same location as HT 2. The "arcade" consists of a fibrous band or series of bands arching over the ulnar nerve.[2] In some cases, the ulnar nerve "sticks to" the fascial walls, keeping it from sliding freely and provoking entrapment pathology. The ulnar nerve changes course as it travels from the dorsal (posterior) to the ventral (anterior) compartments (see Figure 5-7), at the proximal opening of the canal, its tightest portion. The canal consists of the intermuscular septum, fascial fibers, and the epimysium of the triceps muscle. Other anatomists call this connective tissue element an internal brachial ligament.

Clinical Relevance: Myofascial restriction in the region of HT 2 increases traction on the ulnar nerve, predisposing it to damage and contributing to cubital tunnel syndrome.

Palpation of the medial brachium over the Canal of Struthers often elicits a report of tenderness to palpation.[3]

Muscles

- **Biceps brachii muscle:** Flexes the arm when the elbow is in extension. When the elbow flexes, the biceps brachii becomes the most powerful supinator of the forearm.
- **Triceps brachii muscle**: Serves as the main extensor of the forearm. The long head of the triceps steadies the head of the humerus of the abducted arm.

Clinical Relevance: Figure 5-7 illustrates how the edges of the biceps and triceps brachii lie within reach of an acupuncture needle entering HT 2 and thus pose opportunity for trigger point deactivation and proprioceptive influence. However, the main structures associating with the HT channel are neurovascular in nature; i.e., the axillary/brachial/ulnar arteries and the brachial plexus/medial brachial cutaneous/ulnar nerves. Figure 5-7 reveals the presence of the median nerve as well, exposing the neuroanatomical overlap of the HT and PC channels.

Nerves

- **Medial brachial cutaneous nerve (C8, T1):** Supplies the skin on the medial brachium (arm).
- **Ulnar nerve (C8-T1):** Arises as a terminal branch of the medial cord of the brachial plexus, receiving fibers from C8, T1, and often C7. It courses down the medial aspect of the arm and provides articular branches to the elbow joint. At the elbow, it continues posterior to the medial epicondyle and enters the antebrachium (forearm). The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.
- **Median nerve (C6-T1):** Accompanies the brachial artery along the arm but supplies no branches except for some small twigs to the brachial artery. The median nerve does supply articular branches to the elbow as it courses past the joint. Muscular branches supply the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi

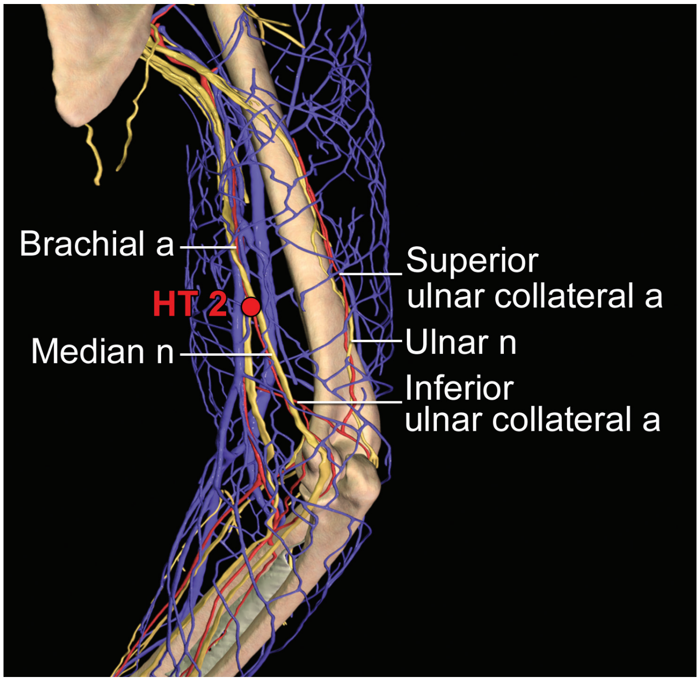

Figure 5-5. The abundance of venous structures at this site (HT 2) on a channel associated with the spirit (HT) explains the point's descriptive title of "Cyan Spirit" or "Blue Death". Note the position of the ulnar nerve as it winds around the humerus here, shifting from the brachium's dorsal to ventral compartment. In vivo, connective tissue tension limits its gliding and sliding capability, leading to nerve compression, stress, or other type of entrapment.

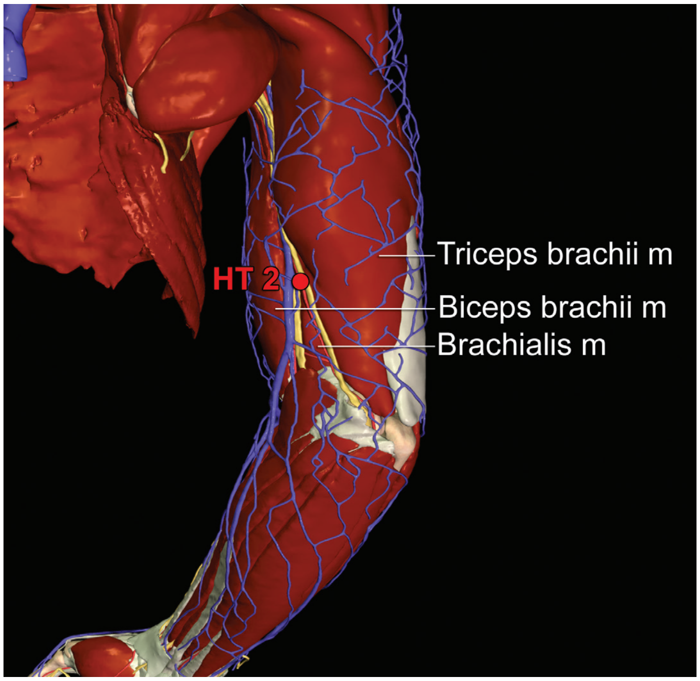

Figure 5-6. This image illustrates the placement of HT 2 along the medial bicipital groove, residing at the intersection of the biceps brachii, triceps brachii, and brachialis muscles.

radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except for the flexor carpi ulnaris and the medial half of the flexor digitorum profundus muscle. The median nerve innervates all thenar muscles except the adductor pollicis and deep head of the flexor pollicis brevis. It supplies the lumbrical muscles for digits II and III, and provides sensation to the skin of the palmar and distal dorsal aspects of the radial three digits (thumb, forefinger, and middle finger), the radial aspect of the ring finger, and adjacent palmar areas. Four branches of the median nerve supply the hand, named the recurrent (thenar), lateral, medial, and palmar cutaneous. The recurrent branch supplies the abductor pollicis brevis muscle, the opponens pollicis muscle, and the superficial head of the flexor pollicis brevis muscle. The lateral branch supplies the 1st lumbrical muscle, the palmar skin, and the skin on the distal dorsal aspects of the thumb and radial half of the index finger. The medial branch supplies the 2nd lumbrical muscle and the skin of the palmar and distal dorsal aspects of the adjacent aspects of the 2nd, 3rd, and 4th digits. The palmar cutaneous branch supplies the skin of the central palmar region.

Clinical Relevance: Cubital tunnel syndrome ranks as the second most common compressive neuropathy in the thoracic limb of humans, with carpal tunnel syndrome as the first.[4] Ulnar nerve compression can impair sensation, reduce the power of muscles supplied by the ulnar nerve, and radiate discomfort along the ulnar nerve's course. Causes include trauma, overuse, and myofascial dysfunction. The canal, or arcade, of Struthers constitutes the site (~HT 2) where the ulnar nerve traverses the intermuscular septum, leaving the anterior and entering the posterior compartments of the brachium; this is also a common source of nerve compression. Nerves need to glide and move longitudinally along their courses. When myofascia or other anatomical components stretch or tether them, this impacts their ability to function normally. The cross section in Figure 5-7 explores the multiplicity of neurovascular structures inhabiting HT 2. These include the ulnar, musculocutaneous, and median nerves; the brachial artery and its venae comitantes; and the basilic vein. Acupuncture, manual therapy, laser therapy, and a host of other physical medicine maneuvers contribute to alleviating compression and restriction of the ulnar nerve.[5]

Vessels

- **Brachial artery:** A continuation of the axillary artery, the brachial artery provides the main arterial supply to the arm. The brachial artery gives rise to the radial and ulnar arteries. Other main branches include the deep artery of the arm (profunda brachii artery) and the superior and inferior ulnar collateral arteries, which help form the elbow arterial anastomoses. The median nerve accompanies the brachial artery as it courses along the brachium.
- **Superior ulnar collateral artery:** This artery arises from the brachial artery near the middle of the arm and travels with the ulnar nerve toward the humerus. It anastomoses with the posterior branch of the ulnar recurrent artery and the inferior ulnar collateral artery which participate in the elbow anastomoses.
- **Brachial veins:** The brachial veins accompany the brachial artery and frequently encompass it, forming a common vascular sheath by means of their anastomotic interconnections. Blood draining from the brachial vein is further pushed along its pathway by the brachial artery's pulsations. The brachial veins form from the veins which travel with the radial and ulnar arteries. They drain into the axillary vein after joining with the basilic vein.
- **Inferior ulnar collateral artery:** This artery arises from the brachial artery about five centimeters proximal to the cubital crease. The inferior ulnar collateral artery joins the elbow anastomoses via by connecting with the anterior branch of the ulnar recurrent artery.
- **Basilic vein:** The basilic vein arises from the ulnar portion of the dorsal venous network of the hand and courses along the ulnar aspect of the forearm. It continues its ascent along the medial portion of the inferior arm (brachium), enters the axilla, and merges with the veins that accompany the brachial artery, thereby forming the axillary vein.

Clinical Relevance: The axillary vein and its tributaries exhibit variations that can complicate invasive procedures and impact neurologic function if they expand onto or otherwise compress neighboring nerves. Venous duplication increases the likelihood of thromboembolism when penetrated by a nerve and/or subjected to stretch.[6] Acupuncture and related techniques applied to this highly neurovascular region can lead to autonomic neuromodulation.

Indications and Potential Point Combinations

- **Rib pain:** HT 2, plus palpate for trigger points and tenderness at the paraspinal region and intercostals space at the level of the rib pain. Caution needling over the thorax.
- **Shoulder and arm pain:** HT 2, plus local trigger points in the brachium, shoulder, and upper back region.
- **Neuropathy and/or paresis in the thoracic limb:** HT 2, plus points along channels related to neuropathic nerves. Address related cervical spinal nerve points.

Figure 5-7. The intimate association of HT 2 with prominent vessels such as the brachial artery becomes evident in this cross section. Expanding the focus to include nearby nerves causes one to realize that nearly all of the peripheral nerves and vessels supplying the distal thoracic limb course through this bundle beneath the point.

- **Chest pain, both cardiac and thoracic wall pain:** After determining the course of action from a conventional medical perspective, for additional pain control, consider HT 2 along with paraspinal electroacupuncture stimulation of the upper thoracic spinal cord segments, such as BL 11-BL 14, as well as GV 14. Less direct and invasive than spinal cord stimulation via implanted electrodes, paraspinal electroacupuncture would share similar goals; i.e., delivery of electrical impulses to several of the most cranial thoracic spinal segments that 1) provide pain relief, 2) reduce frequency and severity of angina attacks, and lower the need for short-acting nitrate.[1]

HT 3

Shao Hai "Lesser Sea"

On the medial (ulnar) end of the cubital crease, in a depression anterior to the medial epicondyle of the humerus that appears when the elbow is flexed. Midway between PC 3 and the medial epicondyle of the humerus.

Muscles

- **Pronator teres muscle:** Pronates the forearm. Flexes the forearm at the elbow.

Clinical Relevance: Figure 5-10 shows the relationship of the more superficial and medial pronator teres to the brachialis muscle. The extensors of the antebrachium occupy the lateral compartment of the elbow. A needle entering HT 3 deeply enough reaches the pronator teres muscle and possibly the brachialis, depending on the nature of the insertion. HT 3 sits where myofascial trigger points in the pronator teres muscle reside. Referred pain issues from HT 3 strongly to the radial aspect of the distal volar antebrachium (from LU 7 to LU 10) with less pronounced pain between the elbow and wrist. "Pronator teres syndrome" leads to wrist pain of neurogenic origin. The median nerve courses between the humeral and ulnar heads of the pronator teres muscle and can become compressed with repetitive pronation/supination motions of the antebrachium.

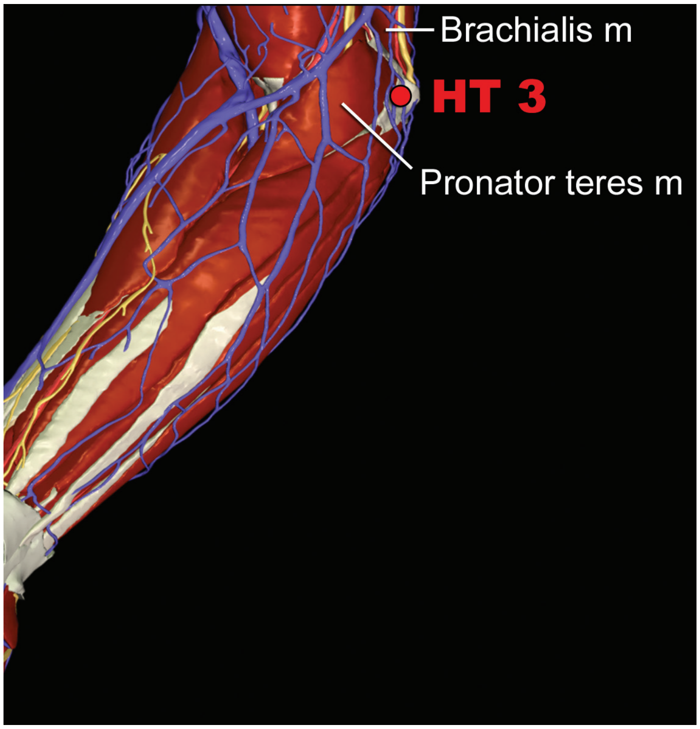

Figure 5-8. Muscles within reach of HT 3 include the pronator teres and brachialis muscles. The pronator teres muscles travels over the median nerve and brachial artery distal to this location (see also Figure 5-10). Myofascial restriction in the medial elbow, including restriction in the pronator teres muscle, furthers median nerve compression mimicking carpal tunnel syndrome. Depending on a patient's anatomy and location of tenderness to palpation, HT 3 might appear as shown here or more radial, within the belly of the pronator teres muscle.

Nerves

- **Medial brachial cutaneous nerve (C8, T1):** Supplies the skin on the medial brachium (arm).
- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Median nerve (C6-T1):** The median nerve forms distal to the axilla, arising from the medial and lateral cords of the brachial plexus. The bulk of the motor input of the median nerve arises from C8 and T1 fibers traveling in the medial cord, while most of the sensory axons of the median nerve derive from the lateral cord with C6 and C7 fibers.[1] After the terminal segments of the lateral and medial cords coalesce to form the median nerve, the nerve accompanies the brachial artery along the arm but supplies no branches except for some small twigs to the brachial artery. The median nerve supplies the elbow joint with articular branches. It passes beneath the bicipital aponeurosis (lacertus fibrosus) and the humeral head of the pronator teres muscle on its way to the forearm. It branches into the anterior interosseous nerve at about 4 cm distal to the medial epicondyle of the humerus where it passes under fascia from either the flexor digitorum superficialis or pronator teres muscle. Its course continues along the anterior interosseous membrane. Before it terminates in the distal forearm, it supplies the pronator teres and pronator quadratus muscles and all of the forearm flexors (including the flexor carpi radialis, the palmaris longus, and the flexor digitorum superficialis muscles), except for the flexor carpi ulnaris and the medial half of the flexor digitorum profundus muscle. Along its way to the distal forearm, the median nerve can experience compression, well before it faces the flexor retinaculum at the wrist, such as between the superficial and deep heads of the pronator teres muscle.[2]
- **Ulnar nerve (C8-T1):** Arises as a terminal branch of the medial cord of the brachial plexus, receiving fibers from C8, T1, and often C7. It courses down the medial aspect of the arm and provides articular branches to the elbow joint. At the elbow, it continues posterior to the medial epicondyle and enters the antebrachium (forearm). The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: The anterior interosseous nerve suffers entrapment from anomalous muscles, trauma, vascular compression, and/or fibrous bands from either the flexor digitorum superficialis or pronator teres muscle. This nerve lies deep within the proximal antebrachium between the flexor digitorum superficialis and profundus muscles. Tension in the pronator teres accentuates anterior interosseous entrapment syndrome.

Abundant restriction in the vicinity of HT 3 places additional pressure or traction on the ulnar nerve, located closer to SI 8 than HT 3, as illustrated in Figure 5-10.

Vessels

- **Inferior ulnar collateral artery:** This artery arises from the brachial artery about 5 cm proximal to the cubital crease. It joins the elbow anastomoses via its connection with the anterior branch of the ulnar recurrent artery.

- **Anterior (branch of the) ulnar recurrent artery:** Arises from the ulnar artery just past the elbow joint. It joins with the ulnar collateral and interosseous recurrent arteries to form the elbow anastomoses. It supplies the brachialis and pronator teres muscles.

- **Basilic vein:** The basilic vein courses along the medial aspect of the arm and ultimately empties into the axillary vein after merging with the brachial veins. The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm. At the elbow, it joins the median cubital vein. The basilic vein accompanies the medial antebrachial cutaneous nerve in the vicinity of HT 3.

Clinical Relevance: According to some, the inferior ulnar collateral artery provides the only direct vascular supply to the ulnar nerve in the section proximal to the cubital tunnel,[4] although connections with the superior ulnar collateral artery lend support. (See Figure 5-10.) If trauma, surgery, scar tissue, and/or inflammation interrupt or diminish extrinsic blood supply to the ulnar nerve, acupuncture and related techniques aidsn in restoring blood supply.

Indications and Potential Point Combinations

- **Psychological disturbance:** depression, mental fatigue brought on by intense emotion, anxiety, insomnia, seizures precipitated by anxiety: HT 3 combined with HT 7, ST 36, LR 3, GV 20.

- **Heart pain with nausea and vomiting:** After instituting appropriate conventional medical care, consider HT 3 plus PC 6, ST 36.

- **Intercostal neuralgia:** HT 3, SI 9 and/or SI 10 as well as tender myofascial trigger points and taut bands in the spinal segmental region associated with the dysfunctional intercostals nerve(s). Palpate for trigger points in the related intercostals muscles.

- **Pain or numbness of the thoracic limb, especially the elbow, from arthritis, nerve entrapment, or myofascial pain; also, cubital tunnel syndrome (a compression/traction neuropathy occurring at the elbow),[3] anterior interosseous nerve syndrome with hand weakness (patient expresses difficulty executing the "pinch" motion); differentiate from brachial neuritis with different locus of injury; pronator syndrome with pain and paresthesias that can mimic carpal tunnel syndrome but differentiable with resisted forearm pronation and other maneuvers:** HT 3, and tender myofascial trigger points in the region that may be precipitating or perpetuating the pain and neural dysfunction. For anterior interosseous nerve syndrome, consider adding PC points (e.g., PC 4-PC 6) associated with the anterior interosseous nerve as well as trigger points in the muscles it supplies, such as the lateral part of the flexor digitorum profundus muscle affecting digits 2 and 3, and the pronator quadrates. The anterior interosseous nerve also sends articular branches to the wrist, suggesting local wrist points such as PC 7.

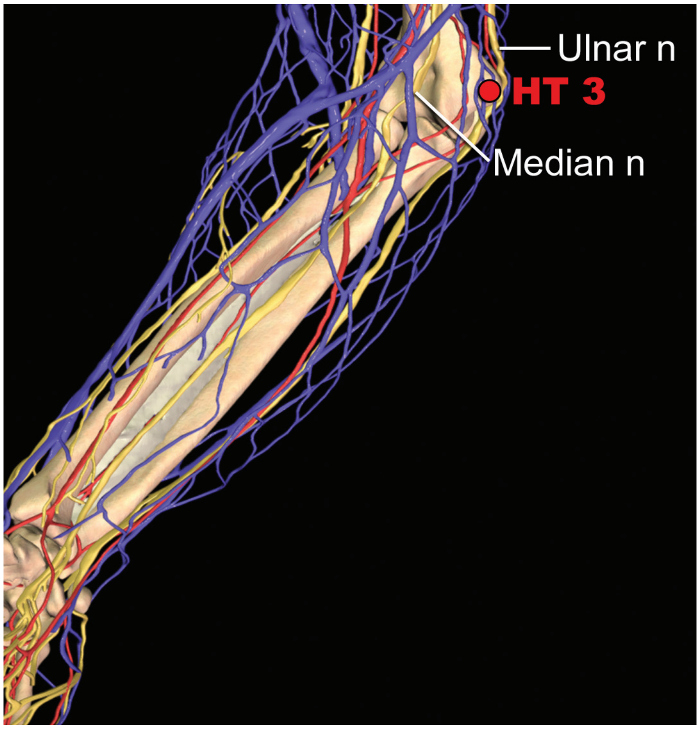

Figure 5-9. The ulnar nerve runs near HT 3, though it directly underlies SI 8, at the ulnar groove. The median nerve comes into the picture when considering HT 3, given its potential for compression by the pronator teres. A more radial location for HT 3, as discussed for the previous figure, would provide relatively more stimulation to the median than the ulnar nerve.

Figure 5-10. Several neurovascular structures sit near HT 3, including the brachial artery and its venae comitantes, the basilica vein, ulnar nerve, and the median nerve. HT 3, as the "Lesser Sea" marks the diminution in size of the brachial artery after it has given off several branches at or near the elbow, including the radial and ulnar arteries as well as the superior and inferior ulnar collateral arteries that produce an anastomosis around the elbow. HT 3 is the "Shao Hai" (Lesser Sea) point on the Shao Yin of the Hand channel. Points at the elbows and knees are also known as "Sea" points where the smaller vessels (streams and rivers) of the forearm are metaphorically connecting to larger distributing or collecting vessels (i.e., the arteries and veins, respectively).

HT 4

Ling Dao "Spirit Pathway"

Proximal to the wrist on its volar aspect, 1.5 cun proximal to the wrist crease and HT 7, on the radial aspect of flexor carpi ulnaris tendon.

Muscles

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints. Also flexes the proximal phalanges at the wrist and metacarpophalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius and ulna.
- **Flexor carpi ulnaris muscle:** Adducts and flexes the hand at the wrist.

Clinical Relevance: Prolonged contraction of the forearm and hand flexors can lead to fatigue and myofascial dysfunction. Activities include motorcycle racing and other high-force, repetitive activities.[1] The cross-sectional anatomy visible in Figure 5-12 illustrates the relationships of the local musculature to the entry site at HT 4, suggesting the angle and depth required for local trigger point deactivation.

Tension in the flexor carpi ulnaris muscle contributes to ulnar nerve lesions at the elbow more commonly than does tension in the flexor digitorum profundus.[2] Ulnar neuropathy at the wrist is more rare and difficult to localize with routine electrophysiologic studies than ulnar neuropathy at the elbow.[3] Myofascial palpation of the tissues along the course of the ulnar nerve often reveals the locus of dysfunction and prompts attention to the site through medical acupuncture and related techniques.

Swelling of the pronator quadratus muscle as well as soft tissue edema outside of the muscle can become visible on radiograph and indicate inflammatory, infectious, or hemorrhagic conditions.[4] Fascia covering the muscle keeps fluid accumulation centralized in this region. Note the thin fat layer in Figure 5-12 between the pronator quadratus and flexor digitorum profundus muscles. This fat plane can become visible on radiographs when this section expands with fluid. The fat layer sits directly below HT 4.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the volar and ulnar aspects of the forearm from the vicinity of HT 2 to HT 7.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles.
- **Anterior interosseous nerve:** A branch of the median nerve, the anterior interosseous nerve supplies the flexor digitorum profundus (lateral, or radial aspect), flexor pollicis longus, and the pronator quadratus muscles. (The ulnar nerve also innervates the flexor digitorum profundus, medial, or radial side.) The anterior interosseous nerve provides articular branches to the wrist joint. Although anatomy texts often show the nerve terminating within the belly of the pronator quadratus muscle, others contend that the anterior interosseous nerve continues on to terminate at the palmar aspect of the radiocarpal and intercarpal joints.

Clinical Relevance: Venipuncture can injure the medial antebrachial cutaneous nerve. The nerve becomes subcutaneous just proximal to the medial epicondyle. It follows the HT channel region to provide cutaneous sensation to the ulnar aspect of the antebrachium.[5] Steroid injection for medial epicondylitis, cubital tumor surgery, arthroscopy of the elbow, and

Figure 5-12. As the most proximal point of the group at the wrist, HT 4 goes by the name "Spirit Pathway" implying its pathway to the Heart, where the spirit resides in Chinese medicine. The vascular conduit, i.e., the ulnar artery, connecting HT 4 to the master pump appears on this cross section just deep to the point.

routine venipuncture can injure the nerve, along with repetitive motion trauma, soft tissue injury, and subcutaneous lipomas. This causes a purely sensory neuropathy. Medical acupuncture and related techniques could be implemented in order to aid in the recovery of medial antebrachial cutaneous nerve injury function.

The ulnar nerve is vulnerable to suffer compression at the wrist from soft tissue expansions such ganglion cysts.[6] Ulnar neuropathy at the wrist takes the form of a mixed motor and sensory neuropathy, purely motor, or purely sensory.[7]

Following repair of the ulnar and median nerves, sympathetic unmyelinated fibers regrow more quickly than sensory myelinated fibers. The relative amount of autonomic versus somatic nerve endings in an acupuncture point locale colors the kind of response the tissue exhibits.

Pressure on the anterior interosseous nerve could cause diagnostic confusion.[8] Patients characteristically describe the discomfort as dull, non-radiating, and achy. Wrist hyperextension worsens the problem in some patients. Myofascial restriction in the flexor muscles of the distal forearm would likely worsen the compression, prompting practitioners to palpate the region and deactivate trigger points that are contributing to the problem. The course of the anterior interosseous nerve belongs more to the PC channel (PC 6, PC 7) than the HT, but myofascial dysfunction can spill over from one channel to another.

Vessels

- **Ulnar artery:** In this region, the dorsal and palmar carpal branches of the ulnar artery anastomose with the radial artery.
- **Ulnar veins:** These paired veins drain the forearm and accompany the ulnar artery. The receive tributaries from muscles lying nearby.

Clinical Relevance: Corticosteroid injection for carpal tunnel syndrome runs the risk of injuring local nerves or vessels. Injection on either side of the palmaris longus tendon can injure the median nerve, while an ulnar approach risks damaging the ulnar artery and nerve.[9]

Indications and Potential Point Combinations

- **Ulnar neuralgia:** Select HT 4 for pain in this region, but also palpate for myofascial restriction and target trigger points. Consider adding proximal ulnar nerve points such as SI 8 or HT 3. Palpate for caudal cervical somatic dysfunction, paying particular attention to the C7-T1 region. Select GV 14 and local points for caudal cervical somatic dysfunction.
- **Wrist or elbow pain:** HT 4 if tender, plus local trigger points. Palpate the musculotendinous junctions of the involved dysfunc-

tional muscles for additional trigger points, to determine the cause of the pain, if it is indeed myofascial, as opposed to articular, or neuropathic.

HT 5

Tong Li "Connecting Li"

Proximal to the wrist on its volar aspect, 1 cun proximal to the wrist crease and HT 7, on the radial aspect of the tendon of the flexor carpi ulnaris muscle.

Note the proximity of the points HT 4, HT 5, HT 6, and HT 7 in Figure 5-11. As such, the cross-sectional anatomy of HT 5 will be similar to HT 4.

Muscles

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints. Also flexes the proximal phalanges at the wrist and metacarpophalangeal joints.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius and ulna.
- **Flexor carpi ulnaris muscle:** Adducts and flexes the hand at the wrist.

Clinical Relevance: Prolonged contraction of the forearm and hand flexors can lead to fatigue and myofascial dysfunction. Activities include motorcycle racing and other high-force, repetitive activities.[2] The cross-sectional anatomy visible in Figure 5-12 illustrates the relationships of the local musculature to the entry site at HT 4, suggesting the angle and depth required for local trigger point deactivation. Structures deep to HT 5 will have a similar layout to HT 4.

Tension in the flexor carpi ulnaris muscle contributes to ulnar nerve lesions at the elbow more commonly than does tension in the flexor digitorum profundus.[2] Ulnar neuropathy at the wrist is more rare and difficult to localize with routine electrophysiologic studies than ulnar neuropathy at the elbow.[4] Myofascial palpation of the tissues along the course of the ulnar nerve often reveals the locus of dysfunction and prompts attention to the site through medical acupuncture and related techniques.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the volar and ulnar aspects of the forearm from the vicinity of HT 2 to HT 7.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles.
- **Anterior interosseous nerve:** A branch of the median nerve, the anterior interosseous nerve supplies the flexor digitorum profundus (lateral, or radial aspect), flexor pollicis longus, and the pronator quadratus muscles. (The ulnar nerve also innervates the flexor digitorum profundus, medial, or radial side.) The anterior interosseous nerve provides articular branches to the wrist joint. Although anatomy texts often show the nerve terminating within the belly of the pronator quadratus muscle, others contend that the anterior interosseous nerve continues on to terminate at the palmar aspect of the radiocarpal and intercarpal joints.

Clinical Relevance: Venipuncture sometimes injures the medial antebrachial cutaneous nerve. The nerve becomes subcutaneous just proximal to the medial epicondyle. It follows the HT channel region to provide cutaneous sensation to the ulnar aspect of the antebrachium.[5] Steroid injection for medial epicondylitis, cubital tumor surgery, arthroscopy of the elbow, and routine venipuncture can injure the nerve, along with repetitive motion trauma, soft tissue injury, and subcutaneous lipomas. This can cause a sensory neuropathy. Medical acupuncture and related techniques aid in the recovery of medial antebrachial cutaneous nerve injury function.

The ulnar nerve suffers compression at the wrist from soft tissue expansions such ganglion cysts.[6] Ulnar neuropathy at the wrist can express itself as a mixed motor and sensory neuropathy, purely motor, or purely sensory.[7]

Following repair of the ulnar and median nerves, sympathetic unmyelinated fibers regrow more quickly than sensory myelinated fibers. The relative amount of autonomic versus somatic nerve endings in an acupuncture point locale colors the kind of response the tissue exhibits.

Pressure on the anterior interosseous nerve could cause diagnostic confusion.[8] Patients characteristically describe the discomfort as dull, non-radiating, and achy. Wrist hyperextension worsens the problem in some patients. Myofascial restriction in the flexor muscles of the distal forearm would likely worsen the compression, prompting practitioners to palpate the region and deactivate trigger points that are contributing to the problem. The course of the anterior interosseous nerve belongs more to the PC channel (PC 6, PC 7) than the HT, but myofascial dysfunction can spill over from one channel to another.

Vessels

- **Ulnar artery:** In this region, the dorsal and palmar carpal branches of the ulnar artery anastomose with the radial artery.
- **Ulnar veins:** These paired veins drain the forearm and accompany the ulnar artery. The receive tributaries from muscles lying nearby.

Clinical Relevance: Corticosteroid injection for carpal tunnel syndrome runs the risk of injuring local nerves or vessels. Injection on either side of the palmaris longus tendon can injure the median nerve, while an ulnar approach risks damaging the ulnar artery and nerve.[9]

The nervi vasorum associated with the ulnar artery figure prominently into the cardiovascular and hemodynamic indications of this point. Note the close association between vessels and HT 5 in Figure 5-13…a theme that characterizes one of the key features of the HT line.

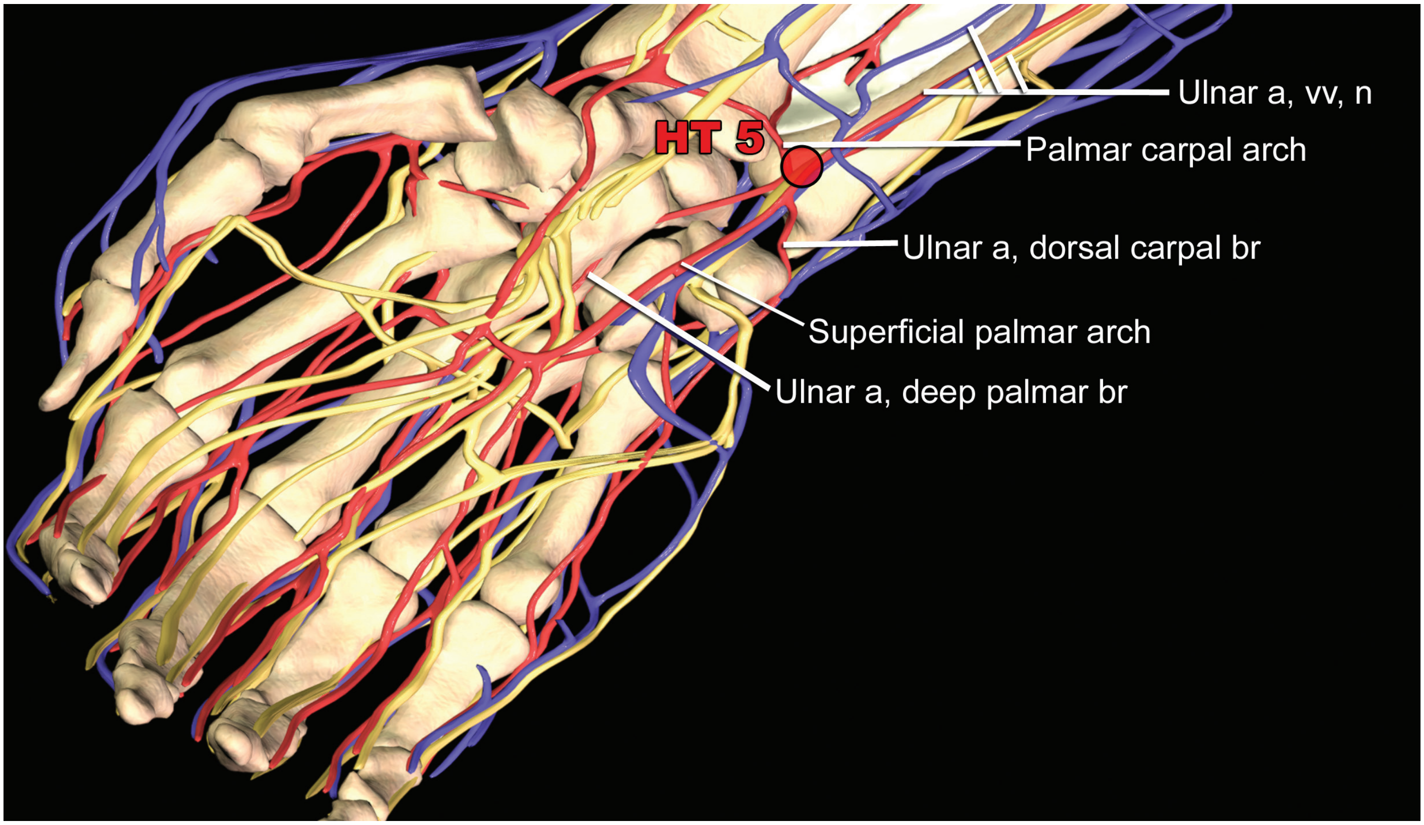

Figure 5-13. HT 5, as “Connecting Li” indicates a connecting place or village at a crossroad. Anatomically, HT 5 lies near two offshoot branches of the ulnar artery. One continues into the palm as the superficial palmar carpal arch. The other links the HT channel to the SI channel via the dorsal carpal branch of the ulnar artery, shown in this figure just distal and ulnar to HT 5. The latter branch constitutes a connecting (transverse) vessel between the HT and SI lines, harkening back to the original conceptualization of acupuncture channels as vascular conduits.

Indications and Potential Point Combinations

- **Emotional issues:** Performance or test anxiety, heart symptoms of emotional origin: HT 5, HT 7, ST 36, GV 20.
- **Angina pectoris:** ST 36, BL 15, BL 20, HT 5, and PC 6 (see below for evidence-based application).
- **Sudden loss of voice, aphasia, hoarseness:** HT 5, CV 23, CV 22, ST 9.
- **Wrist pain:** Palpate for tender areas to determine source of pain (myofascial, arthrodial, neuropathic) and additional points (whether proximal, distal, volar, dorsal, or lateral).

Evidence-Based Applications

- Acupuncture at ST 36, BL 15, BL 20, HT 5, and PC 6 reduced the number of attacks per week in **angina pectoris** patients and reduced ST-segment depression during exercise, possibly indicating protection of the myocardium from ischemia.[1]

HT 6

Yin Xi "Yin Cleft"

Proximal to the wrist on its volar aspect, 0.5 cun proximal to the wrist crease at HT 7, on the radial aspect of the tendon of the flexor carpi ulnaris muscle.

Muscles

- **Flexor digitorum superficialis muscle:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints. Also flexes the proximal phalanges at the wrist and metacarpophalangeal joints.

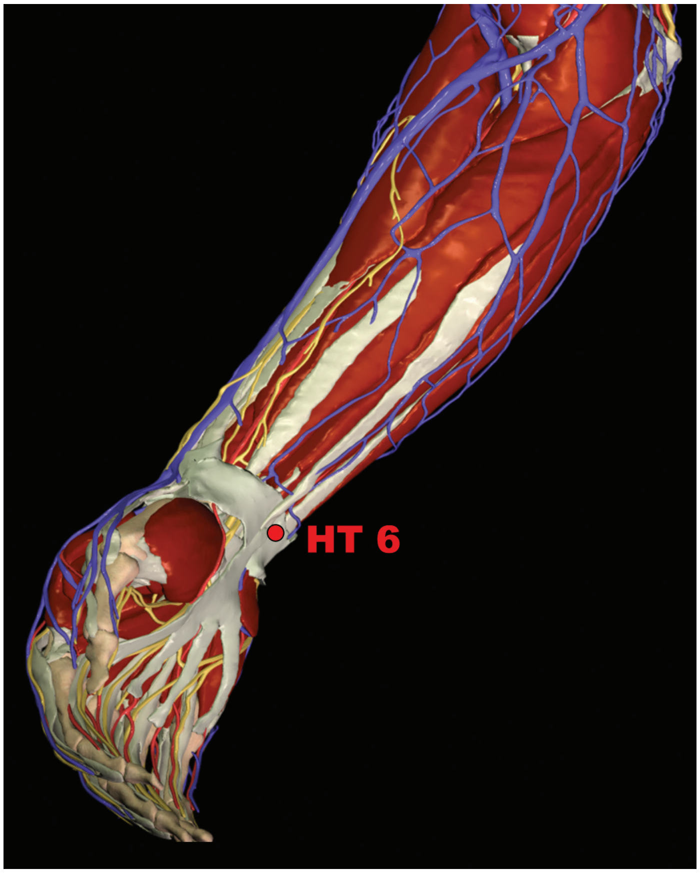

Figure 5-14. Points located at or near myotendinous junctions were historically called "Xi" or "Cleft" points, signifying a division between the muscle and tendon. HT 6, "Yin Cleft" is such a point along the HT channel, considered a Yin channel because it courses along the inner and palmar surface of the thoracic limb. Tender myotendinous junctions signal active trigger points resulting from irritable nociceptors and poor oxygenation relative to normal myotendinous junctions. Myotendinous junctions in the wrist and hand contain a high density of Golgi tendon organs (GTO), particularly in the muscular portion of thejunction (Jozsa L, Balint J, Kannus P, et al. Mechanoreceptors in human myotendinous junction. *Muscle & Nerve.* 1993;16:453-457). GTO's work with muscle spindles to signal position and respond to active contraction in the muscle as well as passive stretch. Free nerve endings in these zones serve as pain receptors. In addition to GTO's and free nerve endings, the myotendinous junction also contains Ruffini and Pacinian corpuscles, i.e., mechanoreceptors that aid the GTO and free nerve endings in orchestrating coordinated and protective control over complex bodily movements. Thus, myotendinous junctions house four types of sensory nerve endings: Type I (Ruffini corpuscles, pressure sensors), Type II (Pacinian corpuscles, also pressure sensors), Type III (GTO's) and Type IV (free nerve endings).

- **Flexor digitorum profundus muscle:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.
- **Pronator quadratus muscle:** Pronates the antebrachium, binds the radius and ulna.
- **Flexor carpi ulnaris muscle:** Adducts and flexes the hand at the wrist.

Clinical Relevance: Prolonged contraction of the forearm and hand flexors can lead to fatigue and myofascial dysfunction. Activities include motorcycle racing and other high-force, repetitive activities.[1] The cross-sectional anatomy visible in Figure 5-15 illustrates the relationships of the local musculature to the entry site at HT 6, suggesting the angle and depth required for local trigger point deactivation.

Tension in the flexor carpi ulnaris muscle contributes to ulnar nerve lesions at the elbow more commonly than does tension in the flexor digitorum profundus.[2] Ulnar neuropathy at the wrist is more rare and difficult to localize with routine electrophysiologic studies than ulnar neuropathy at the elbow.[3] Myofascial palpation of the tissues along the course of the ulnar nerve often reveals the locus of dysfunction and prompts attention to the site through medical acupuncture and related techniques.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Note: Communicating branches pass between the median and ulnar nerves.**
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Venipuncture can injure the medial antebrachial cutaneous nerve. The nerve becomes subcutaneous just proximal to the medial epicondyle. It follows the HT channel region to provide cutaneous sensation to the ulnar aspect of the antebrachium.[4] Steroid injection for medial epicondylitis, cubital tumor surgery, arthroscopy of the elbow, and routine venipuncture can injure the nerve, along with repetitive motion trauma, soft tissue injury, and subcutaneous lipomas.

Figure 5-15. As with the other HT points near the wrist, the ulnar nerve and artery stand in close approximation.

A sensory neuropathy can result. Medical acupuncture and related techniques will support neural recovery.

The ulnar nerve suffers compression at the wrist from soft tissue expansions such ganglion cysts.[5] Ulnar neuropathy at the wrist can express itself as a mixed motor and sensory neuropathy, purely motor, or purely sensory.[6]

Following repair of the ulnar and median nerves, sympathetic unmyelinated fibers regrow more quickly than sensory myelinated fibers. The relative amount of autonomic versus somatic nerve endings in an acupuncture point locale colors the kind of response the tissue exhibits.

Vessels

- **Ulnar artery:** Arises near the neck of the radius in the cubital fossa. It provides several branches, including the anterior and posterior (branches of the) ulnar recurrent arteries, the common interosseous artery, the anterior and posterior interosseous arteries, and the dorsal and palmar carpal branches, which anastomose with the radial artery.
- **Ulnar veins:** These paired veins drain the forearm and accompany the ulnar artery. The receive tributaries from muscles lying nearby.

Clinical Relevance: Note the proximity of the ulnar nerve and artery to HT 6 in Figure 5-15. Needling directly into the ulnar artery and nerve at this site could cause hemorrhage and pain. Instead, palpate for the pulse prior to inserting a needle. Angle the insertion toward the muscles instead. That said, nervi vasorum associated with the ulnar artery figure prominently into the cardiovascular and hemodynamic indications of this point.

Indications and Potential Point Combinations

- **Chest pain, angina pectoris, palpitations, chest pressure:** HT 6, with HT 2 or HT 3, PC 6, GV 14, BL 10-BL 15
- **Anxiety, insomnia, night sweats:** HT 6 with PC 4, PC 5, or PC 6, GV 20, LR 3
- **Local pain:** HT 6 if tender, along with other trigger points in the flexor muscles.

HT 7

Shen Men "Spirit Gate"

On the wrist crease, in the articular region between the pisiform bone and the ulna, in a depression on the radial aspect of the flexor carpi ulnaris tendon. When needling a patient who is in the prone position, HT 7 can be needled on the ulnar side of the flexor carpi ulnaris tendon, close to its insertion and directed toward the radial side of the tendon.

Note how Figure 5-17 reveals proximity of the HT channel to the median of the volar antebrachium where the PC line lies. This intimate association anatomically explains why the HT and PC point exhibit commonality in their indications.

Tendons

- **Flexor digitorum superficialis tendon:** Flexes the middle phalanges of the fingers at the proximal interphalangeal joints. Also flexes the proximal phalanges at the wrist and metacarpophalangeal joints.
- **Flexor digitorum profundus tendon:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.
- **Flexor carpi ulnaris tendon:** Adducts and flexes the hand at the wrist.

Clinical Relevance: Figure 5-18 reveals the close assortment of tendons coursing beneath HT 7. Falling and bracing oneself with the outstretched hand occasionally injure flexor and extensor tendons.[12] Of the flexor tendons involved in Colles' fractures, the flexor digitorum profundus to the index finger and the flexor pollicis longus are most likely to be affected. Some flexor tendon ruptures in patients with rheumatoid arthritis occur as a result of wear by bone spurs or direct invasion of hypertrophic tenosynovium.[13]

Medical acupuncture and related techniques such as laser therapy would improve tendon health and healing capacity through direct tissue effects on injured segment and relaxation of the tissue in the muscle belly to reduce traction on the tendon.

Those who participate in grip sports sometimes develop entrapment syndromes.[14] See next section on nerves regarding their entrapments by tendons and other entities. Use acupuncture and related techniques to relax myotendinous regions and foster flexibility in wrist and antebrachial structures.

Nerves

- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal

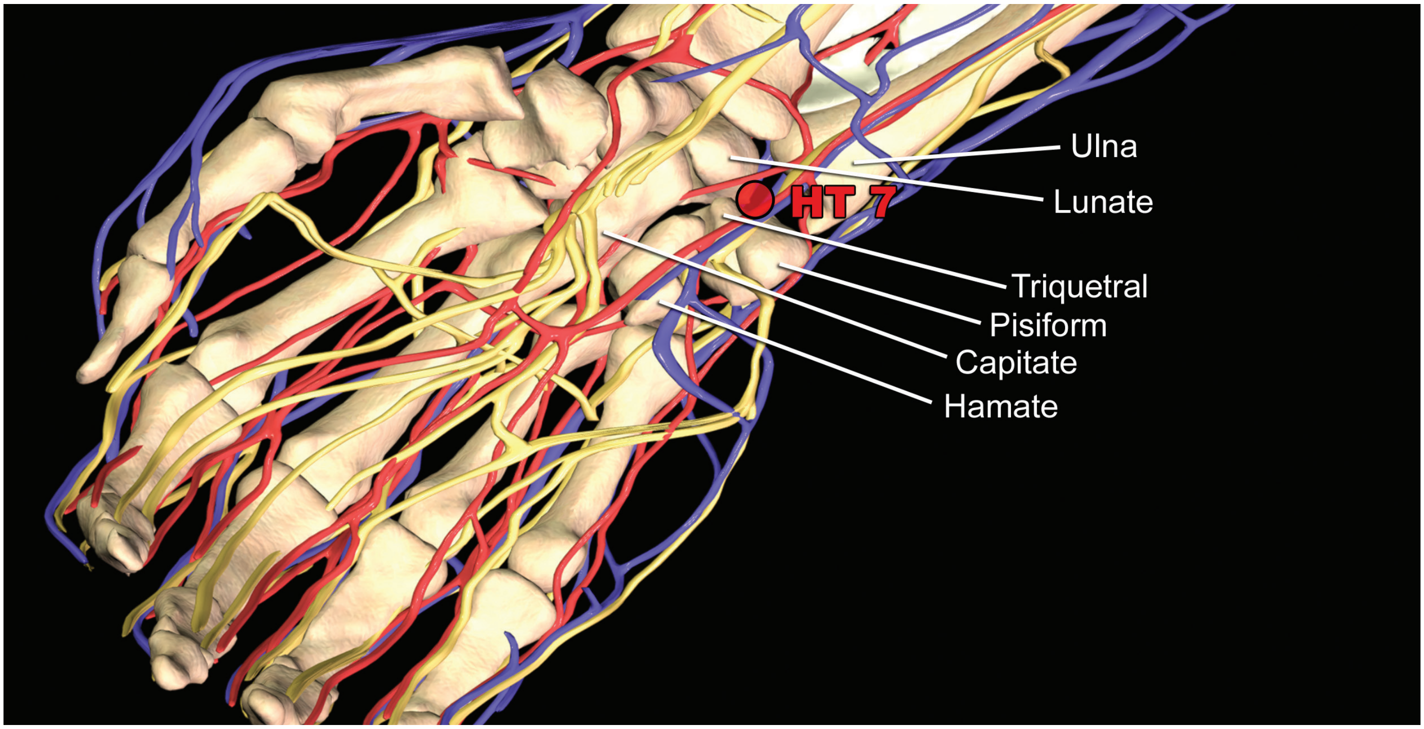

Figure 5-16. HT 7, "Spirit Gate" or "Spirit Door", is considered a passageway to the spirit that allows acupuncture to induce calm. Auricular Shen Men has been dubbed the "Valium® point" for its similarly calming effects. Whereas auricular Shen Men invokes trigeminovagal influences to calm the nervous system, body Shen Men (i.e., HT 7), modulates autonomic function by influencing sympathetic fibers in the nervi vasorum and ulnar nerve.

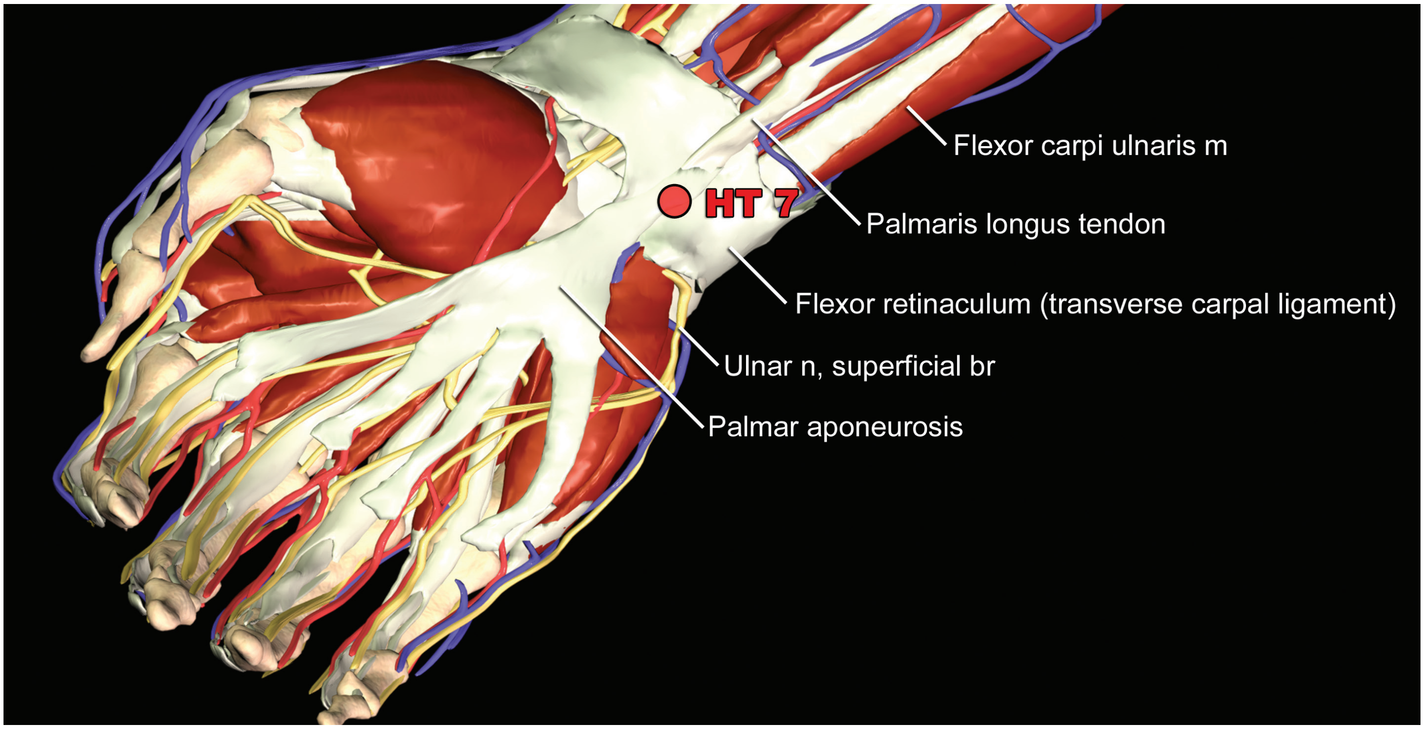

Figure 5-17. Connective tissue and myofascial restriction in the flexor compartment of the wrist produces pain and limits movement in the wrist. Acupuncture, massage, and laser therapy in the vicinity of HT 7 reduces tension in the structures appearing in this image as well as underlying tissue, depending on the depth that the stimulation reaches. See Figure 5-18 to study the cross-sectional anatomy at the level of HT 7.

palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Some anatomists contend that three different tunnels exist in the wrist and that Guyon's canal is frequently misrepresented or confusingly outlined. They define the tunnels as 1) a carpal tunnel deep to the flexor retinaculum; 2) the canalis ulnaris (Guyon's canal) between two layers of the flexor retinaculum; and 3) the canalis pisohamatum that issues the deep branch of the ulnar nerve into the hypothenar eminence.[15]

Ulnar nerve entrapment in the wrist, called Guyon's canal syndrome, refers to a compression neuropathy at the wrist or hand that can cause loss of motor, sensory, or both motor and sensory function within the ulnar nerve distribution.[16] Various growths, degenerative conditions, inflammation, and trauma in the vicinity of the ulnar nerve injure it. Specific processes include ganglion cysts, anomalous musculotendinous arches, lipomas, ulnar neuropathy, hamate fractures, ulnar hand trauma, and occupational requirements for wrist hyperextension over long periods of time.

Ozdemir et al describe Guyon's canal as a 4.0 – 4.5 cm long tunnel starting proximal to the hypothenar eminence and extending to the fibromuscular arch at the hypothenar eminence.[17] The palmar carpal ligament, palmaris brevis, and fibrous tissue build the roof of the canal. The flexor digitorum profundus, transverse carpal ligament, the pisohamate and pisometacarpal ligaments form the floor. The flexor carpi ulnaris, pisiform bone, and abductor digiti minimi create the ulnar aspect of the canal. Its radial side comprises the hook of the hamate, transverse carpal ligament, and digital flexor tendons.

Guyon's canal courses along the groove between HT 7 (see Figure 5-16) and HT 8 (Figure 5-19). Note the relationship between HT 7 in Figure 5-16 and the ulnar nerve, artery, and vein it overlies. Acupuncture and related techniques such as massage and laser therapy applied to HT 7 and its myofascial vicinity invites the tissue to relax and relieve pressure on the nerve. Carpal tunnel syndrome, a median nerve entrapment syndrome, at times produces ulnar neuropathy as tension in the wrist extends to involve additional nerves. In addition, postoperative fibrosis after carpal tunnel surgical release can contribute to ulnar nerve entrapment in Guyon's canal.

Vessels

- **Ulnar artery:** Arises near the neck of the radius in the cubital fossa. It provides several branches, including the anterior and posterior (branches of the) ulnar recurrent arteries, the common interosseous artery, the anterior and posterior interosseous arteries, and the dorsal and palmar carpal branches, which anastomose with the radial artery.
- **Ulnar veins:** These paired veins drain the forearm and accompany the ulnar artery. The receive tributaries from muscles lying nearby.

Clinical Relevance: Aneurysm of the ulnar artery appears after traumatic injury to the hand in sports activities such as a basketball dunk.[18] Take care to not penetrate the ulnar artery aneurysm with an acupuncture needle.

One complication of steroid injection for carpal tunnel syndrome involves ulnar artery ischemia.[19] Acupuncture and related techniques improve tissue circulation and can serve as helpful adjuncts in such situations.

The main indications for HT 7 include anxiety and insomnia. The ability of HT 7 to impact the psyche likely relates to the abundant autonomic fibers adjacent to the point, including the

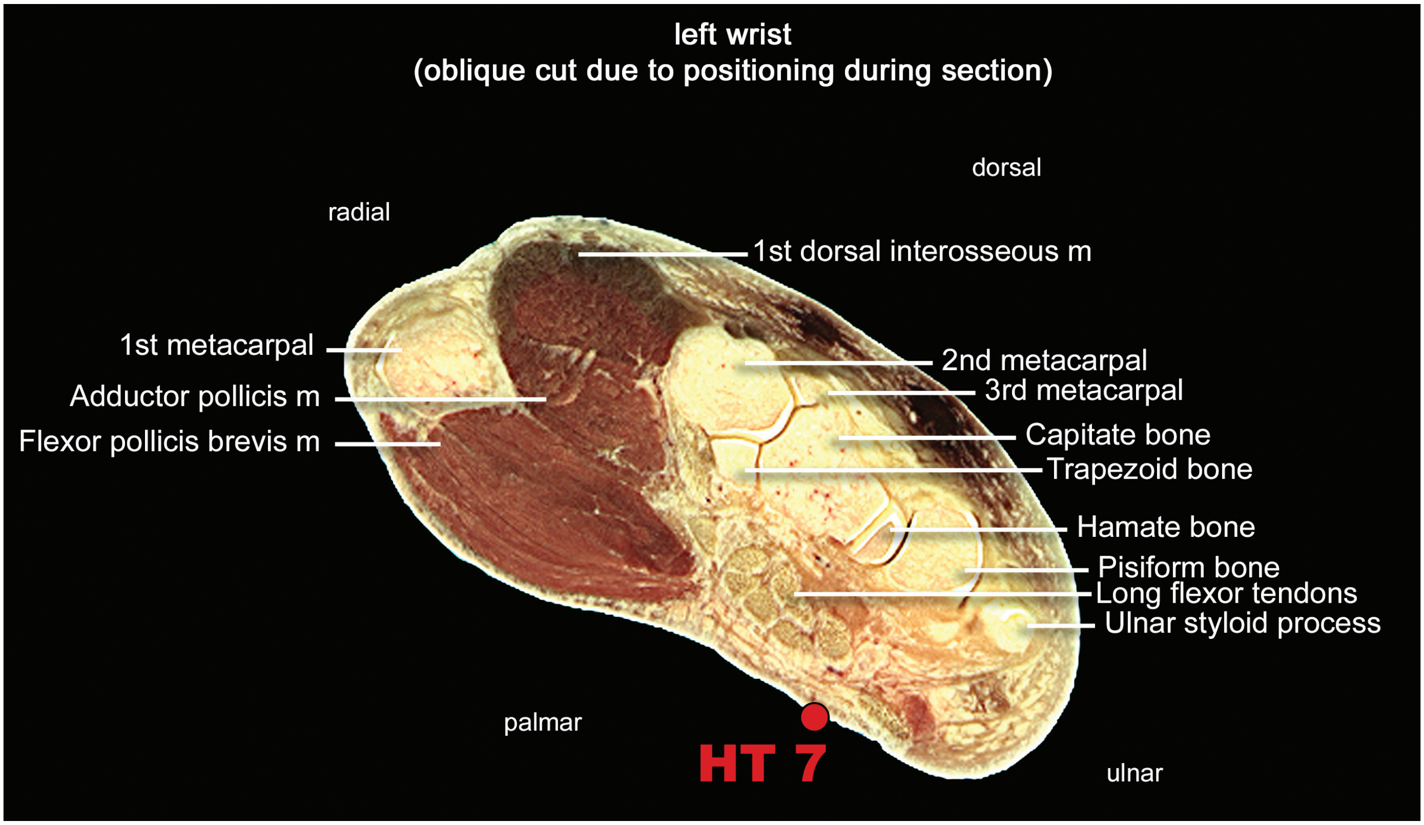

Figure 5-18. The ulnar vessels and nerve appear directly below HT 7 in this cross section, on the ulnar aspect of the long flexor tendon groups.

nervi vasorum of the ulnar artery and sympathetic fibers in the ulnar nerve.

Indications and Potential Point Combinations

- **Mental-emotional agitation; depression; stress-related palpitations, angina pectoris, hypertension, seizures, memory loss, or insomnia:** HT 7, plus PC 7, HT 3, LR 3, ST 36
- **A feeling of heat in the palms, thirst for cold drinks:** HT 7, LI 4, ST 36, ST 44, LR 3
- **Emergence agitation in pediatric patients:** HT 7, LI 4

Evidence-Based Applications

- **Stress**[1]
- **Insomnia**[2]
- **Post-stroke anxiety:** HT 7, GV 20, GV 24, Yintang (GV 24.5), GV 26, LI 4, LR 3, and PC 6.[20]
- Capsicum (hot pepper) plasters applied to HT 7 reduced **emergence agitation in pediatric patients undergoing tonsillectomy and/or adenoidectomy.**[21]
- Acupuncture at LI 4 and HT 7 immediately after induction of anesthesia significantly lowered pain and agitation scores in children after **bilateral myringotomy and tympanostomy.**[22]
- Acupressure at HT 7 improves sleep quality and reduces anxiety in **insomniacs.**[23,24]
- Acupuncture at HT 7 and BL 40, along with CV 3, BL 23, CV 6, LU 9, LR 3, and LR 2 reduced **nocturnal enuresis in children** in a Chinese case series.[25]
- Acupuncture at HT 7, PC 6, GV 26, SP 6, and GV 20 improved **mental depression after stroke** in a Chinese case series.[26]
- Acupuncture at HT 7 in rats sensitized to morphine significantly decreased dopamine release in the nucleus accumbens and the behavioral activity induced by a systemic morphine challenge. This suggests that the beneficial effect of acupuncture for morphine addiction may work by inhibiting the neurochemical and behavioral **sensitization to morphine.**[3]
- Acupuncture at HT 7, but not at PC 6 or a tail point, significantly prevented a decrease in extracellular dopamine levels in the nucleus accumbens during **withdrawal from ethanol.** It also significantly prevented an increase in accumbal dopamine levels subsequent to an ethanol challenge, in chronic ethanol-treated rats. These results indicate that HT 7 helps normalize dopamine release in the mesolimbic system in chronic ethanol-treated rats.[4]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[5]
- Neural tracer investigation found central neural pathways from the heart and acupuncture points PC 6 and HT 7 in the middle cervical, stellate, and T4 sympathetic ganglia and the T2 to T6 spinal ganglia. Sites of overlap were also found in the brain and spinal cord, illustrating the interrelationship of PC 6, HT 7, and **autonomic regulation of heart function.**[6]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with **Sjögren's syndrome.**[7]
- Laser acupuncture significantly outperformed sham laser for

the treatment of **mild to moderate depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[8]

- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes.**[9]
- Electroacupuncture at CV 4, GV 20, SP 6, KI 3, and HT 7 may have afforded a modulating positive effect on **psychogenic and non-psychogenic erectile dysfunction.** It improved the quality of erection and restored sexual activity in 39% of patients.[10]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[11]

HT 8

Shao Fu "Lesser Palace"

On the palm of the hand, between the 4th and 5th metacarpal bones, in the area where the tip of the 5th digit touches the palm when a tight fist is made. Usually occurs between the two transverse palmar creases.

Fascia

- Palmar aponeurosis: the deep fascia over the palm that covers the underlying soft tissues and flexor tendons. The tendon of the palmaris longus fuses with the palmar aponeurosis and the underlying flexor retinaculum (transverse carpal ligament) at the wrist. The palmar aponeurosis appears in Figure 5-17.

Clinical Relevance: Dupuytren contracture develops when collagen nodules and cords manifest and shorten the palmar fascia, causing digital flexion deformity.[2] This fibroproliferative disorder more commonly afflicts the ring and little fingers along the HT channel. Recurrence after surgical correction is common. Prevention and treatment with nonsurgical methods such as physical therapy, soft tissue manual therapy, stretch, laser therapy, and acupuncture at HT 8 and surrounding region should be tried before fasiotomy or fasciectomy.

Muscles and Tendons

- **Flexor digitorum superficialis tendons to the 4th and 5th digits:** Flex the middle phalanges of the fingers at the proximal interphalangeal joints. Also flex the proximal phalanges at the wrist and metacarpophalangeal joints.
- **Flexor digitorum profundus tendons to 4th and 5th digits:** Flex the distal phalanges at the distal interphalangeal joints of the fingers. Aid flexion of the hand.
- **4th lumbrical muscle:** Flexes the digit at the metacarpophalangeal joint and extend the interphalangeal joint.
- **3rd palmar interosseous muscle:** Adducts the digits toward the axial line. Assists the lumbrical muscles in extending the interphalangeal joints and flexing the metacarpophalangeal joints.
- **4th interosseous dorsalis muscle:** Abducts digits from the axial line. Acts with the lumbrical muscles to extend the interphalangeal joints and to flex the metacarpophalangeal joints.

Clinical Relevance: HT 8 lands at a particularly muscular section of the hand, explaining its applications for hand pain and nerve entrapment. Because needling a sensitive region such as the palm causes discomfort, myofascial release and laser therapy will likely be more readily accepted for trigger point deactivation and fascia work.

Nerves

- **Palmar cutaneous branch of the ulnar nerve:** Supplies the skin on the medial (ulnar) aspect of the palm and wrist.
- **Common palmar digital nerves:** Arise from the median nerve and the superficial branch of the ulnar nerve. They branch to become the proper palmar digital nerves. They provide sympathetic motor supply to the skin of the palmar surfaces of the

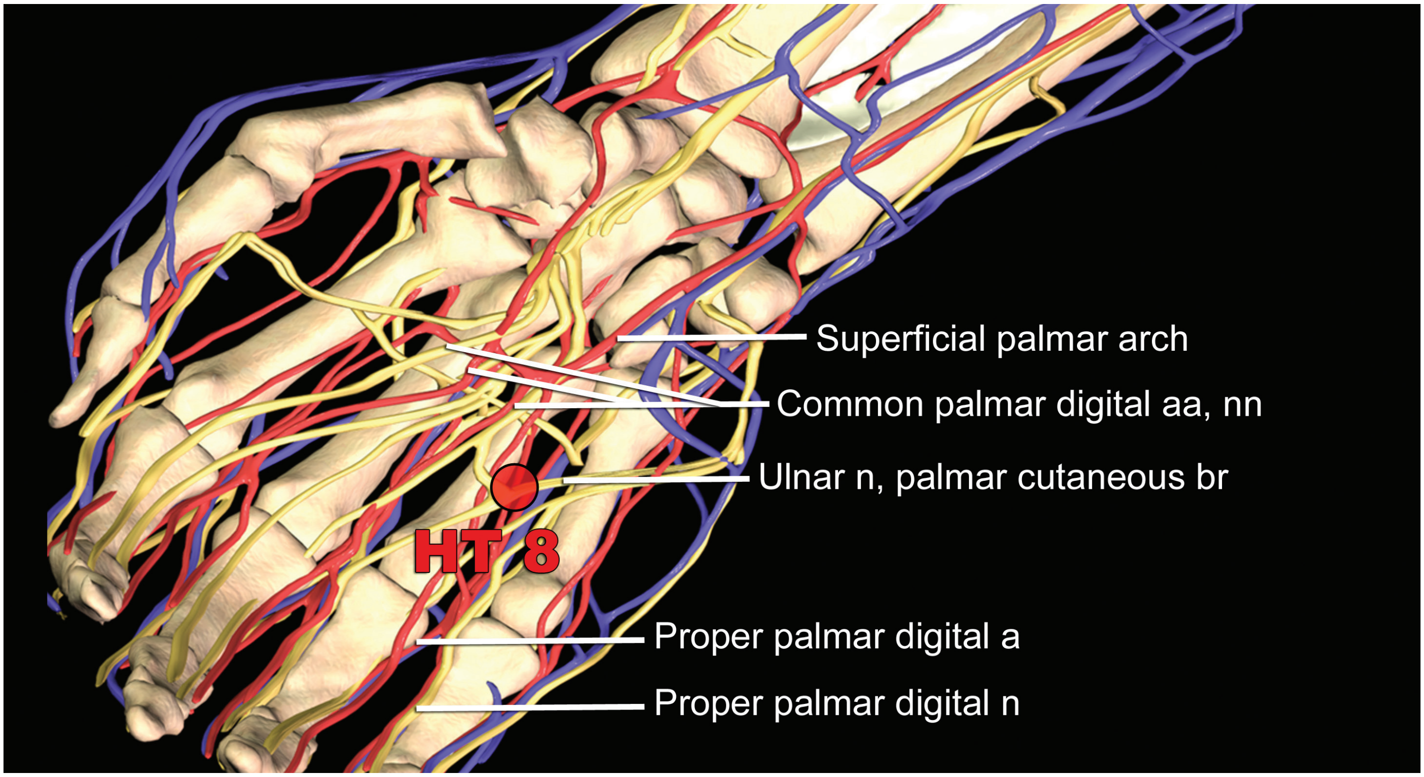

Figure 5-19. The Chinese name for HT 8, "Shao Fu" employs the term "Shao" or "Lesser" for a point along the HT like Shao Hai did for HT 3. "Shao" suggests the channel's anatomic term "Shao Yin of the Arm". Too, HT 8 resides near PC 8, "Palace of Toil"; refer to Figures 9-23 to 9-26 for anatomical comparisons. In contrast to PC 8, the neurovasculature structures near HT 8 are indeed somewhat "lesser" considering they supply the ring and little fingers rather than the index and middle digits. As such, the palace where HT 8 resides is anatomically less well endowed. Note, as well, the size difference in the gap between metacarpals IV and V (at HT 8) as opposed to that between II and III (PC 8).

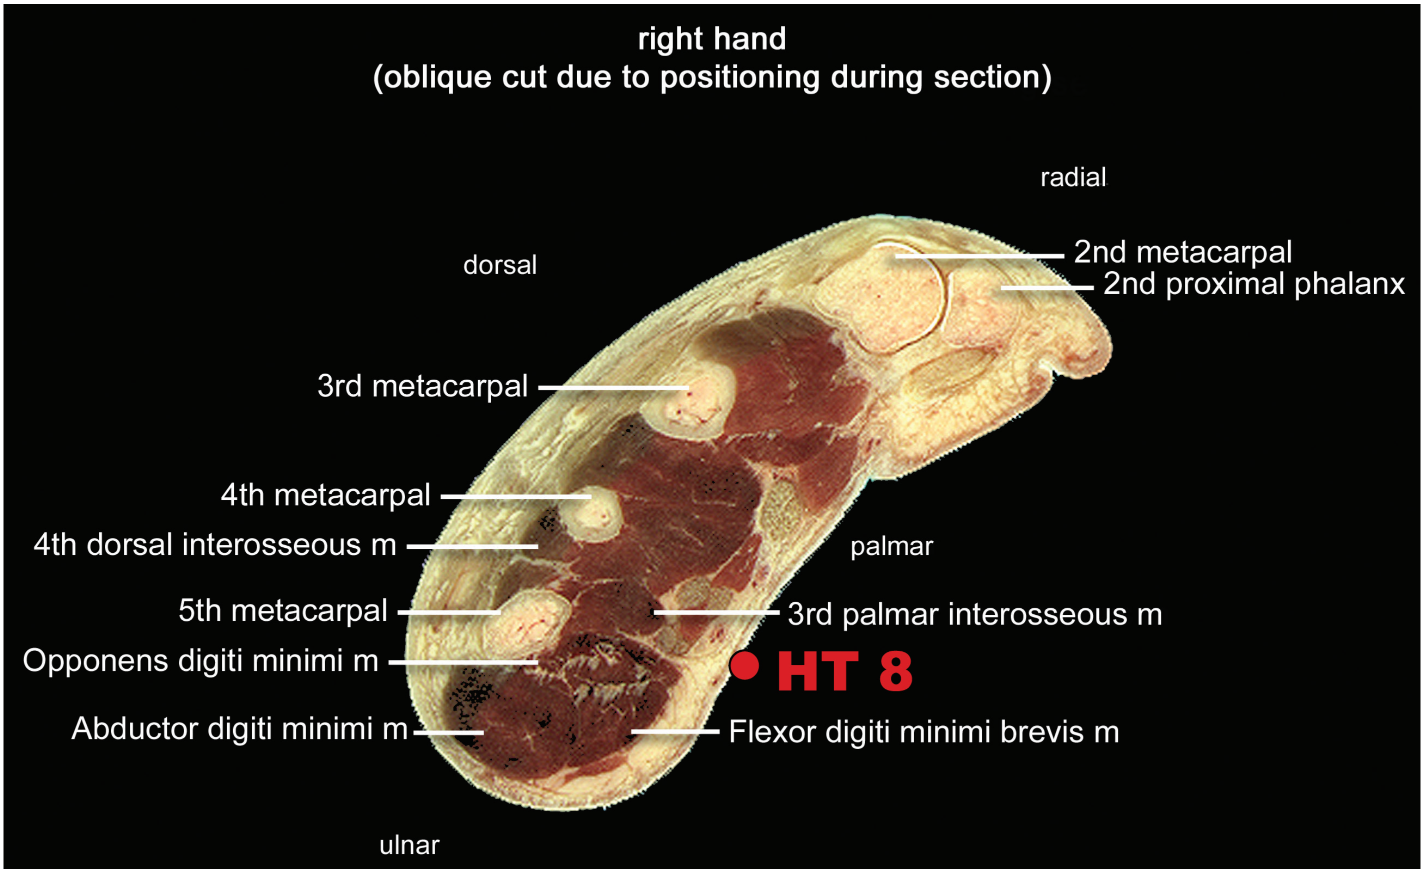

Figure 5-20. At first, the muscularity of HT 8 appears to overshadow the vasculature in this cross section, visible as small, oblong red structures superficial to the muscular structures. These arteries are part of the superficial palmar arterial arch or its branches. Remember that the arteries of the hand house a rich supply of nervi vasorum, i.e., autonomic nerves that control blood vessel diameter in response to changes in temperature and psychological states.

adjacent sides of two digits. The proper palmar digital nerve branches supply the dorsum of the fingertip, in the nail bed region. The proper palmar digital nerve branches from the ulnar nerve supply the palmar and dorsal skin on the medial side of the 4th digit and the entire 5th digit and the respective nail beds. The proper palmar digital nerves originating from the median nerve supply the palmar skin and nail bed of the thumb, index, and middle finger, as well as the radial side of the ring finger (4th digit).

- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: The highly muscular region around HT 8 (shown in Figure 5-20) emphasizes the possibility of ulnar nerve entrapment secondary to hand strain and repetitive motion injury. Anomalous muscle trajectories commonly occur in this region, increasing the potential for nerve compression at Guyon's canal. For example, the flexor digiti minimi brevis has been shown to traverse Guyon's canal where ulnar tunnel syndrome arises.[3] Anatomical variations also affect the abductor digiti minimi muscle[4] and the palmaris brevis.

Vessels

- **Superficial palmar arch:** This constitutes the main termination of the ulnar artery. The superficial palmar arch gives rise to three common palmar digital arteries. These arteries anastomose with the palmar metacarpal arteries, which arise from the deep palmar arterial arch. In contrast to the superficial palmar arch which arises mainly from the ulnar artery, the radial artery provides the main arterial basis for the deep palmar arch. The superficial and deep palmar arterial arches serve as the main sources of blood supply to all structures in the human hand. Preservation of fetal arteries in dominant hands may account for the preservation of complete superficial arterial arches into adulthood.[5]
- **Common palmar digital artery for 4th and 5th digits:** Each common palmar digital artery divides into proper palmar digital arteries, which give rise to a dorsal branch innervating the finger

tips with vessels known as the dorsal branches of the proper palmar digital arteries. The proper palmar digital arteries course along the adjacent sides of digits II through IV.

- **Common palmar digital veins for 4th and 5th digits:** The superficial and deep palmar venous arches accompany the superficial and deep palmar arterial arches.

Clinical Relevance: Acute digital pain, discoloration, reduced skin temperature, and cyanosis without Raynaud syndrome should prompt one to consider the diagnosis of acute digital ischemia.[6] Consider referral for microsurgical exploration and embolus localization. An aneurysm of the ulnar artery, atrial fibrillation, or thoracic outlet syndrome can contribute to the development of digital embolism. Ulnar pseudoaneurysm is another possible etiology. Vascular wall damage can occur secondary to needling trauma, emphasizing the need for caution when introducing acupuncture needles into highly vascular territory. Delaying recognition and aggressive microsurgical treatment raises the possibility of the need for finger amputation. While laser therapy, massage, and acupuncture can facilitate recovery from ischemic events, these therapies should be pursued as appropriate and not delay invasive care when warranted.

Raynaud's phenomenon affects the body's extremities by causing an exaggerated vasospastic response to temperature change and/or psychological stress.[7] Patients with systemic sclerosis (also known as scleroderma) and other connective tissue diseases develop Raynaud's as a secondary problem. Primary Raynaud's phenomenon is related to functional alterations in the endothelium of blood vessels. Acupuncture provides relief of Raynaud's phenomenon through neurologic and, possibly, anti-inflammatory effects on cytokine levels.[8]

Indications and Potential Point Combinations

- **Autonomic arousal, including fever, sweating, especially in the palms; feelings of heat in the palms or burning sensations in the hands; palpitations, chest pain:** HT 8, if such a strong intervention seems required, plus consideration of HT 5, PC 6, and PC 7, as well as ST 36 and GV 20.
- **Neural compromise, including paresthesias, paresis, or paralysis in the thoracic limb:** Outline the defective neurologicpathways including the affected spinal cord segments and address accordingly.
- **Raynaud's syndrome:** HT 8 if required; although LI 4, PC 6, ST 36, and LR 3 would be more readily accepted by most patients. Include laser therapy and massage when possible to HT 8 and PC 8.

Evidence-Based Applications

- Acupuncture stimulation of HT 8, BL 66, and LR 2 effectively reduced elevated body temperature induced by **bacterial inflammation,** in part by suppressing hypothalamic production of pro-inflammatory cytokines.[1]

HT 9

Shao Chong "Lesser Rushing"

On the radial side of the base of the nail of the 5th digit, the width of a Chinese leek leaf from the corner of the nail.

Nerves

- **Dorsal branches of proper palmar digital nerve:** Arise from the ulnar nerve (C8-T1).

Clinical Relevance: The dorsal sensory nerve reaches the nail bed at the ting points, or end points of each channel.[3] These sites, whether or not they are classical acupuncture points, can improve sensation in digits with compromised nerve supply.

Vessels

- **Dorsal branches of proper palmar digital artery of the radial side of the 5th digit:** Arise from the proper palmar digital arteries, which in turn arise from the superficial palmar arterial arch, which comes from the ulnar artery.

Clinical Relevance: The dorsal branches of the proper palmar digital artery contain a rich supply of nervi vasorum that, when stimulated with an acupuncture needle, can lead to profound hemodynamic shifts. This makes HT 9 one of the prime points for recovery from vasovagal episodes.

Indications and Potential Point Combinations

- **Sympathetic hyperarousal: Mania, palpitations:** HT 9 with PC 7, PC 6
- **Coma, stroke, shock other loss of consciousness states; resuscitation:** HT 9 plus PC 9 and GV 26 (strongly stimulated with a pecking motion)
- **Hyperthermia:** HT 9, bled for extreme conditions, GV 20, LR 2, LR 3.
- **Raynaud phenomenon,** which may be due either to a primary disease such as Fabry disease, systemic sclerosis, or other microangiopathies, or secondary Raynaud's due to a local defect in normal vascular responses in the face of cold temperature or emotional stress causing digital blanching); secondary causes would likely respond more quickly and favorably:[1] HT 9, LI 4, PC 6, ST 36, LR 3, Baxie (in the web spaces between the fingers)
- **Vascular dementia:** Jing-well, or ting points, improve memory in rats with experimental vascular dementia.[4]

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[2]

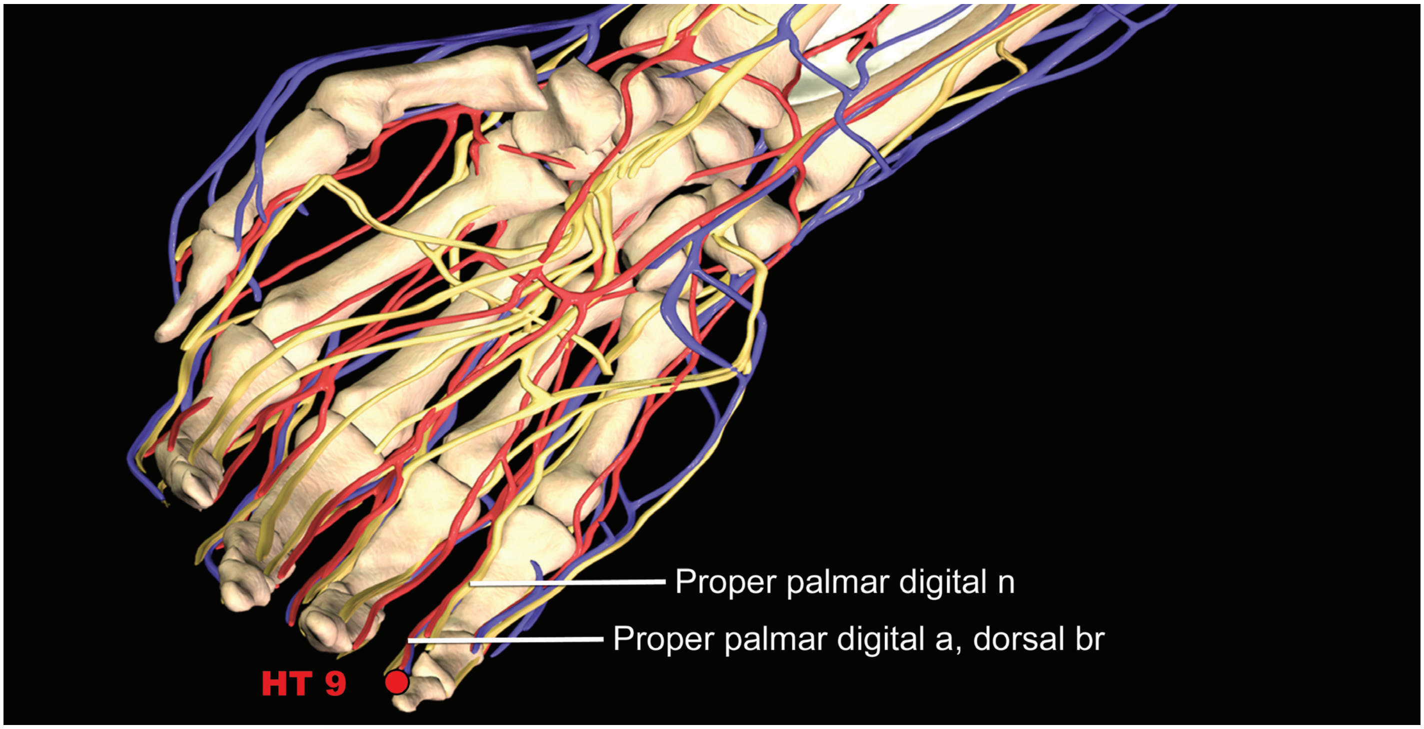

Figure 5-21. The substantial sympathetic supply of nerves affecting the microvasculature near the nails helps explain why certain points such as HT 9 or "Lesser Surge" find their way into treatments for shock and collapse.

Channel 6:: The Small Intestine (SI)

The Small Intestine channel begins on the little finger near the ulnar side of the fingernail. It migrates toward the wrist along the ulnar aspect of the hand, and takes a short detour to the dorsal distal antebrachium before resuming its ulnar aspect journey to the ulnar groove at the elbow. From there it ascends to the shoulder and ultimately makes it to the ear, but only after zigzagging somewhat erratically over the scapula and lateral face.

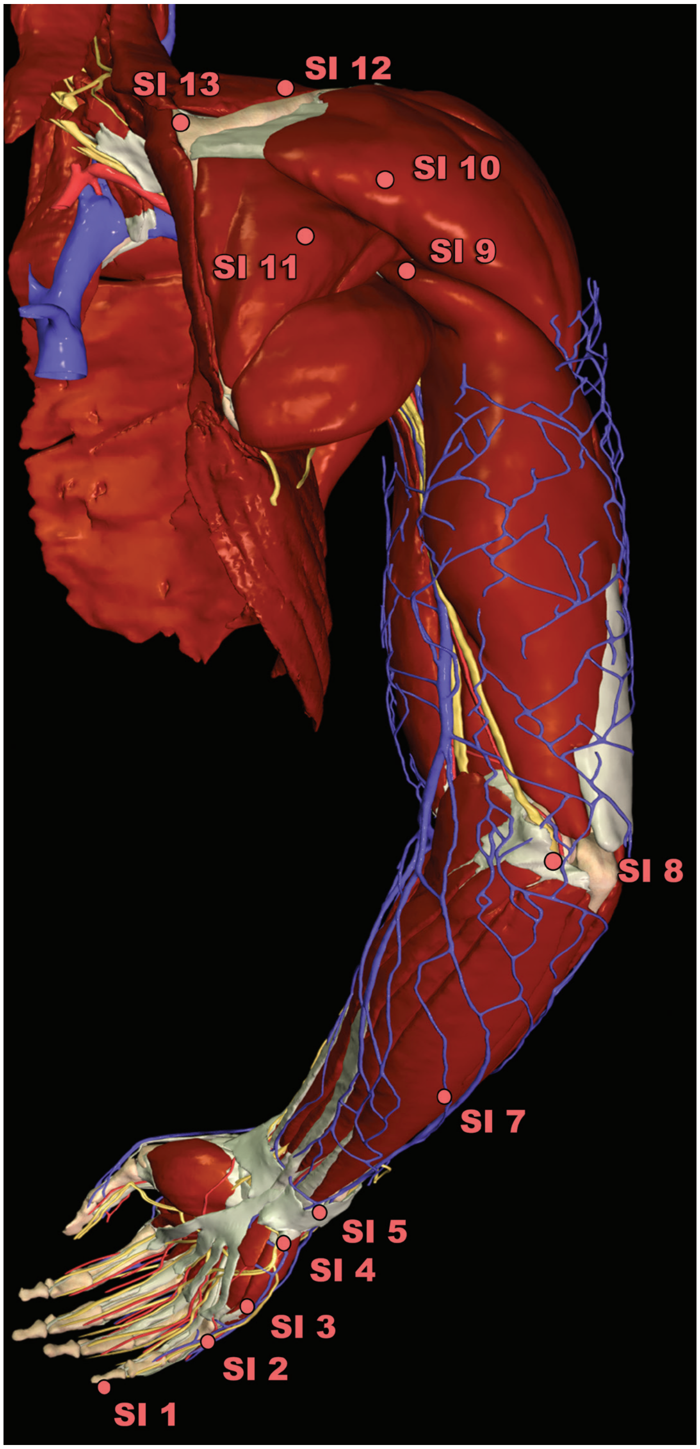
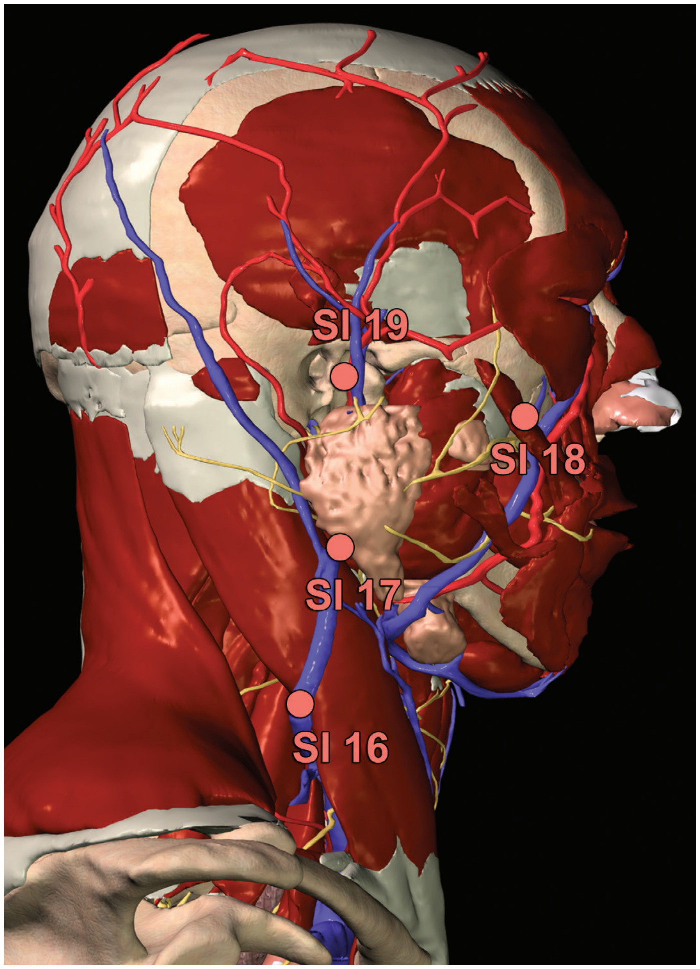
SI 9
SI 8
SI 7
SI 6
SI 5
SI 4
SI 3
SI 2
SI 1



The anatomical structures beneath the surface trajectory of the Small Intestine channel frequently correspond to the clinical indications given for points along the channel. Points SI 1 to SI 8 relate intimately with the ulnar nerve and its branches. As such, indications for these points include problems related to structures supplied by the ulnar nerve: elbow pain, sensory deficits, ulnar neuralgia, or motor deficits of the flexor carpi ulnaris or the ulnar portion of the flexor digitorum profundus. The SI points scattered over the posterior shoulder address myofascial pain in the shoulder and upper back.



Indications of SI points on the head and neck pertain mostly to problems along the SI channel including pain in the temporomandibular joint, neck, and ear, as well as torticollis.

SI 1

Shao Ze "Lesser Marsh"

Ulnar to the nail base of the 5th digit, the width of a Chinese leek leaf from the corner of the nail.

Nerves

- **Dorsal branches of proper palmar digital nerve:** Arise from the ulnar nerve (C8-T1). The dorsal branches of the proper palmar digital nerves supply branches to the dorsum of the tip of the little finger and nail bed, and the ulnar aspect of the ring finger.

Clinical Relevance: SI 1 is called the "milk let-down point". Lactation requires appropriate responses from the master autonomic control switch, i.e., the hypothalamus. Stimulation of SI 1 activates the C8/T1 spinal cord segments, just cranial to the level at which the sympathetic portion of the spinal cord begins. As the most distal point on the SI channel, SI 1 receives the richest autonomic innervation per unit area of any SI point on the thoracic limb. The ulnar nerve arises from the most caudal spinal segments (i.e., those closest to the mammary glands) forming the brachial plexus. The concatenation of these concepts explains how SI 1 became popular to stimulation lactation.

Vessels

- **Dorsal branches of proper palmar digital artery of the ulnar side of the 5th digit:** Arise from the proper palmar digital arteries, which in turn arise from the superficial palmar arterial arch, which comes from the ulnar artery.

Clinical Relevance: Autonomic offshoots of the ulnar nerve become the nervi vasorum of arterioles at SI 1. These afferents impel neuromodulatory influences from the fingertip to the spinal cord and brain and serve to regulate autonomic tone in the upper body.

Indications and Potential Point Combinations

- **Pain problems along SI and BL channels: torticollis, neck and throat pain, eye pain, occipital headache, severe shoulder pain or ulnar neuropathy:** SI 1 plus tender points local to the pain problem, with BL points located at the relevant spinal cord segments, BL 60, GV 20.
- **Fever and chills:** SI 1 plus ST 36, GV 20.
- **Stroke, coma, loss of consciousness, epilepsy:** SI 1, GV 20
- **Mastitis, hypogalactia, other lactation disorders:** SI 1, ST 18, CV 17, LI 4

Evidence-Based Applications

- Electroacupuncture (EA) at SI 1 **improved lactation quantity and maintained prolactin levels** significantly better than EA at LI 1 according to a Chinese study.[1]

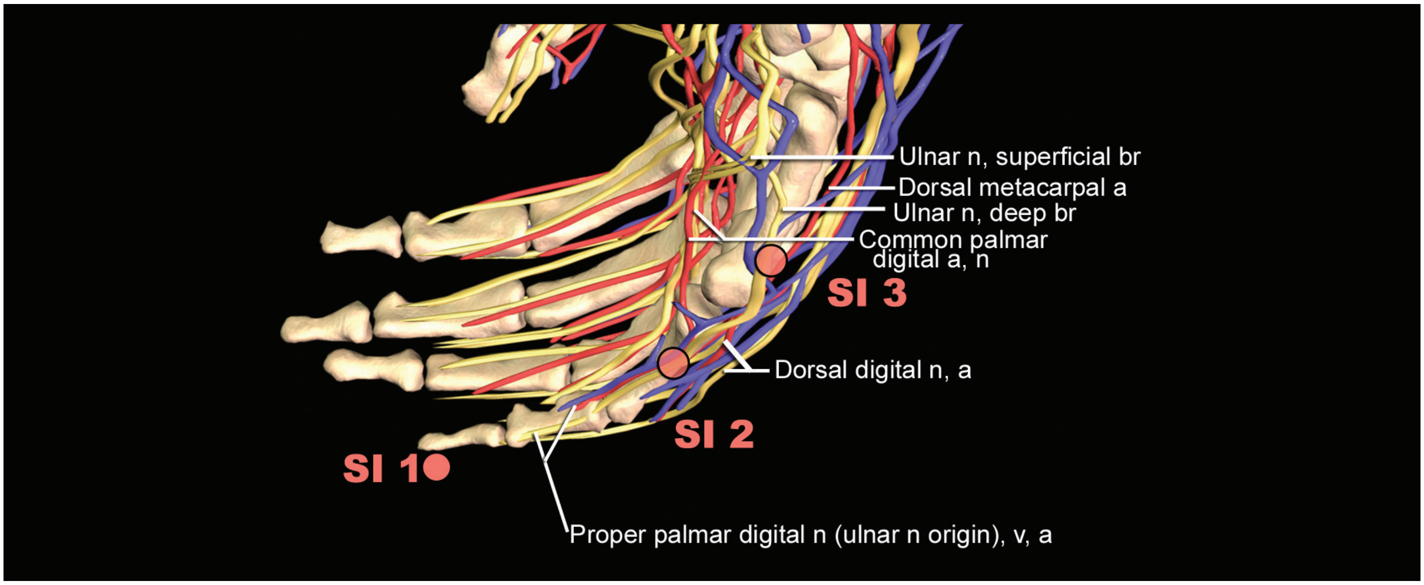


Figure 6-1. According to Nigel Wiseman[2] the original meaning of the character for "Shao", as in "Shao Ze", meant "extremely small". This view of the vascular structures coursing to the fingers indicates how the dorsal branches of the proper palmar digital arteries peter out by the time they inhabit the fingertips. Their "marshiness" or ability to suffuse the nail bed with blood becomes minimal at this site. That said, however, the considerations relevant to neuromodulation pertain to ways in which the abundant nervi vasorum activate the autonomics body-wide.

SI 2

Qian Gu "Front Valley"

On the ulnar side of the little finger, in a depression distal to the 5th metacarpophalangeal joint.

Muscles

- **Abductor digiti minimi muscle of the hand:** Abducts the little finger at the metacarpophalangeal joint. Refer to Figure 6-4 for the anatomic representation of the origin, belly, and insertion of the abductor digiti minimi muscle.

Clinical Relevance: Pathologic nodules and cords that develop in patients with Dupuytren's disease arise from the fascia of the palm and digits. They contain contractile myofibroblasts that shorten and diminish range of motion of the metacarpophalangeal and proximal interphalangeal joints, occasionally involving the distal interphalangeal joint.[1] Digital cords in Dupuytren's contracture will, at times, form within one finger; these isolated cords typically afflict the ulnar aspect of the little finger, within SI channel territory. Cords in this digit may arise from the musculotendinous junction of the abductor digiti minimi or other sites within the finger. They lead to flexion deformities of the proximal interphalangeal joint. Early acupuncture, massage, stretching, and laser therapy may counteract the otherwise inevitable shortening of these myofascial bands that require surgery.

The myotendinous insertion of the abductor digiti minimi muscle (seen on Figure 6-4) contains Golgi tendon organs that serve as proprioceptive sensory receptors that sense stretch and signals force produced by the muscle. Acupuncture treatment at SI 2 will influence impulses sent to the spinal cord and affect muscle firing.

Nerves

- **Common palmar digital branches of the superficial branch of the ulnar nerve:** Supply sympathetic motor innervation to the palmar and dorsal skin of the little finger and ulnar half of the ring finger.
- **Dorsal digital nerves:** Supply the ulnar aspect of the little finger, derived from the ulnar nerve.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as supplies sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), as well as the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Patients with amyotrophic lateral sclerosis (ALS) experience hand muscle wasting that usually affects the thenar muscles and spares, to some degree, the hypothenar muscles such as the abductor digiti minimi.[2] Although the ulnar nerve supplies both the first dorsal interosseous muscle and the abductor digiti minimi, the former undergoes atrophy in ALS

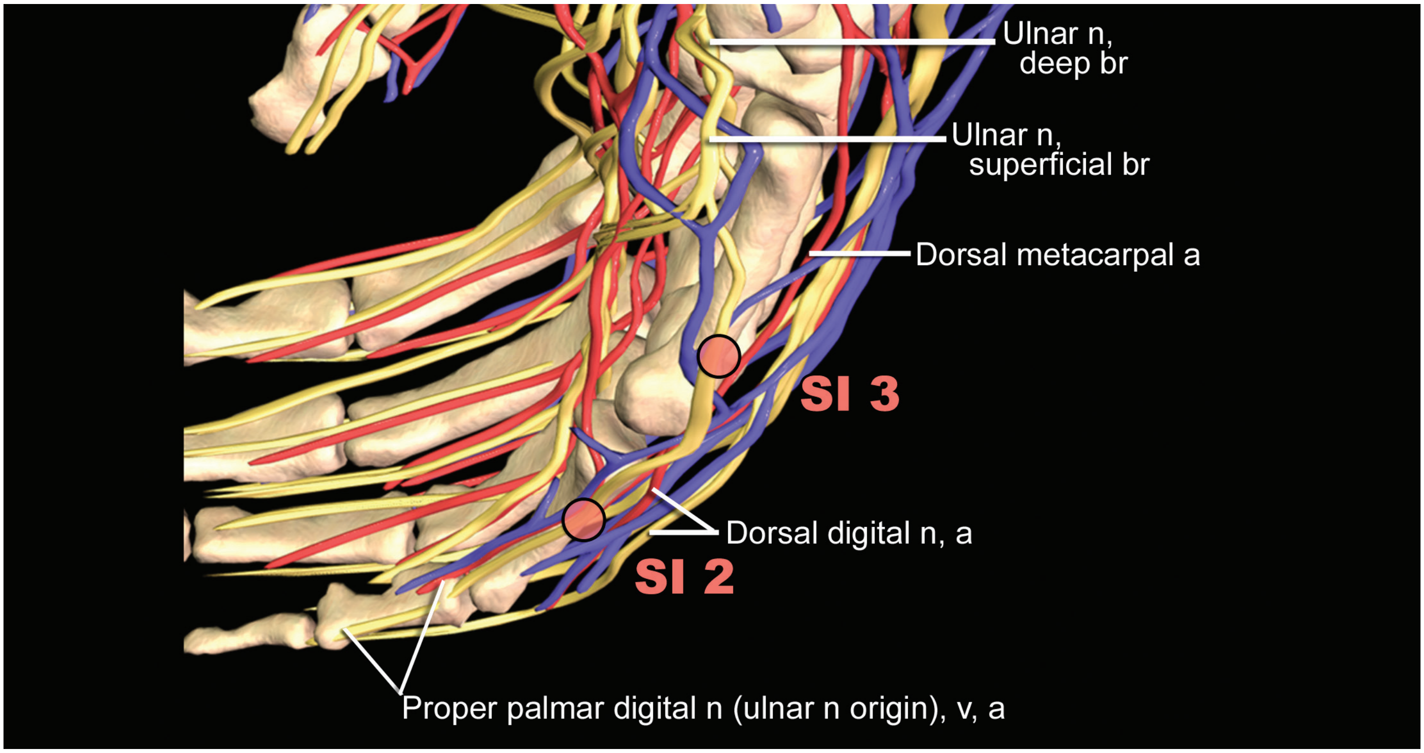

Figure 6-3. Viewing the 5th metacarpophalangeal joint as a mountain facing the fingertip, "Front Valley" (SI 2) and "Back Ravine" (SI 3) refer to the depressions on either side. Note the numerous neurovascular structures crossing this region.

while the latter less so. Whether the underlying mechanism relates to ion channel differences, cortical influences, or differential oxidative stress, this phenomenon called the "split hand syndrome" is considered a useful diagnostic sign in early cases of ALS, with a high degree of specificity. If a patient complains of having problems with a pincer or precision grip, consider ALS within the differential. Although acupuncture and related techniques may assist in preserving hand function, these treatments should not delay appropriate referral and diagnostics.

Metacarpophalangeal (MCP) joint pain in the 5th digit from degenerative joint disease affects local neurovasculature and muscle tension. Acupuncture and related techniques alleviate joint pain by impacting local neurovascular control and reducing myofascial restriction. Acupuncture for joint pain would typically include, for this joint, SI 2 and SI 3.

Vessels

- **Dorsal digital artery:** Arises from the dorsal carpal branch of the ulnar artery.
- **Proper palmar digital artery:** Arises from the superficial palmar arch, derived from the ulnar artery.

Clinical Relevance: Isolated digital cords in cases of Dupuytren's contracture can overlie, displace, or otherwise disturb neurovascular structures of the finger.[3] Resulting pressure or traction on nerves and vessels could produce neuropathic pain and circulatory compromise. Acupuncture and related techniques can loosen the muscles and fascia as well as improve circulation and nerve function.

Indications and Potential Point Combinations

- **Numbness or pain in the pinky finger:** SI 2, plus isolate sources of discomfort to determine whether osseous, arthrodial, neural, or myofascial in origin and treat accordingly.
- **Headache originating in the neck:** SI 2, BL 10, GB 20, GB 21, GV 14, GV 20, and associated trigger points.

SI 3

Hou Xi "Back Stream"

On the ulnar side of the little finger, in a depression proximal to the metacarpophalangeal joint when a loose fist is made, at the dorsal/palmar skin junction. Some advise needling from SI 3 in the direction of LI 4.[1]

Muscles

- **Abductor digiti minimi muscle of the hand:** Abducts the little finger (5th digit).
- **Flexor digiti minimi brevis muscle:** Flexes the proximal phalanx of the little finger.
- **Opponens digiti minimi muscle:** Allows the little finger to oppose the thumb.
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.

Clinical Relevance: Ulnar tunnel syndrome at the hand occurs usually as a result of ganglions, cysts, repetitive motion injury, bicycling, lipomas, and other activities in which the wrist is hyperextended for prolonged periods of time or during which continued pressure impacts the ulnar nerve in the hypothenar eminence. For those cases in which myofascial dysfunction is restricting nerve gliding and reducing circulation, acupuncture and related techniques relaxes the tissue, improves hemodynamics, and facilitates neural repair. The image in Figure 6-4 shows that aspect of the hand impacted by these activities or growths. The motor branch of the ulnar nerve inhabits the ulnar tunnel; the superficial branch appears here beneath SI 3.

Nerves

- Ulnar nerve (C8-T1): The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles.

Clinical Relevance: The benefits of SI 3 for neck pain likely arise from the spinal cord neuromodulation afforded by this distal, muscular point on the SI line. Afferent input arises from muscle, joint, skin, and vascular tissues. This multifaceted information arises at C8/T1 at the bottom or most caudal spinal cord segments. It then ascends along the neck to the head, inducing analgesia along the SI channel and its myofascial continuity.

Ulnar nerve entrapment at the elbow accounts for 20% of focal neuropathies, making it the second most common entrapment neuropathy.[8] Acupuncturists should keep this in mind, because when treating weakness of the ulnar-innervated hand muscles, one should determine the source of nerve injury and not only the result. Patients with ulnar nerve entrapment at the elbow exhibit sensory disturbances along ulnar nerve territory, elbow pain, and weakness in the intrinsic hand muscle supplied by the ulnar nerve. The adductor digiti minimi, i.e., the 3rd palmar interosseous muscle, often displays more weakness than the abductor digiti minimi; this causes Wartenberg's sign where the little finger remains abducted. The pattern and extent of motor compromise correspond to the components of the ulnar nerve that are damaged. In other cases, the pinky may "override" the ring finger, when tone in the adductor overrides that of the abductor.

Guyon's canal syndrome, a compression neuropathy of the ulnar nerve in the wrist or hand, can cause loss of sensory, motor, or their combined functions.[9] Acupuncture treatment of Guyon's canal syndrome would likely require inputs directed toward points on both the HT and SI lines local to the wrist, hand, and elbow.

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Dorsal digital artery:** Arises from the dorsal carpal branch of the ulnar artery.

Clinical Relevance: Variants in musculature local to the wrist can lead to ulnar and median entrapment as well as thrombosis in the vessels.[10]

Indications and Potential Point Combinations

- **Neck, shoulder, and back pain and myofascial restriction:** SI 3, BL 62, tender trigger points, BL 10, GV 20, BL line points related to the involved spinal segment.
- **Neurologic dysfunction affecting the thoracic limb, especially in the ulnar nerve distribution:** SI 3 plus additional points along the ulnar nerve, including SI 8 (needle carefully); add cervical spinal nerve root points to address involved spinal segments. Consider adding Baxie (web space points on the hand) and LI 4.
- **Tinnitus:** SI 3, TH 5, local ear points and trigger points of muscles attaching to the temporal bone, BL 10.

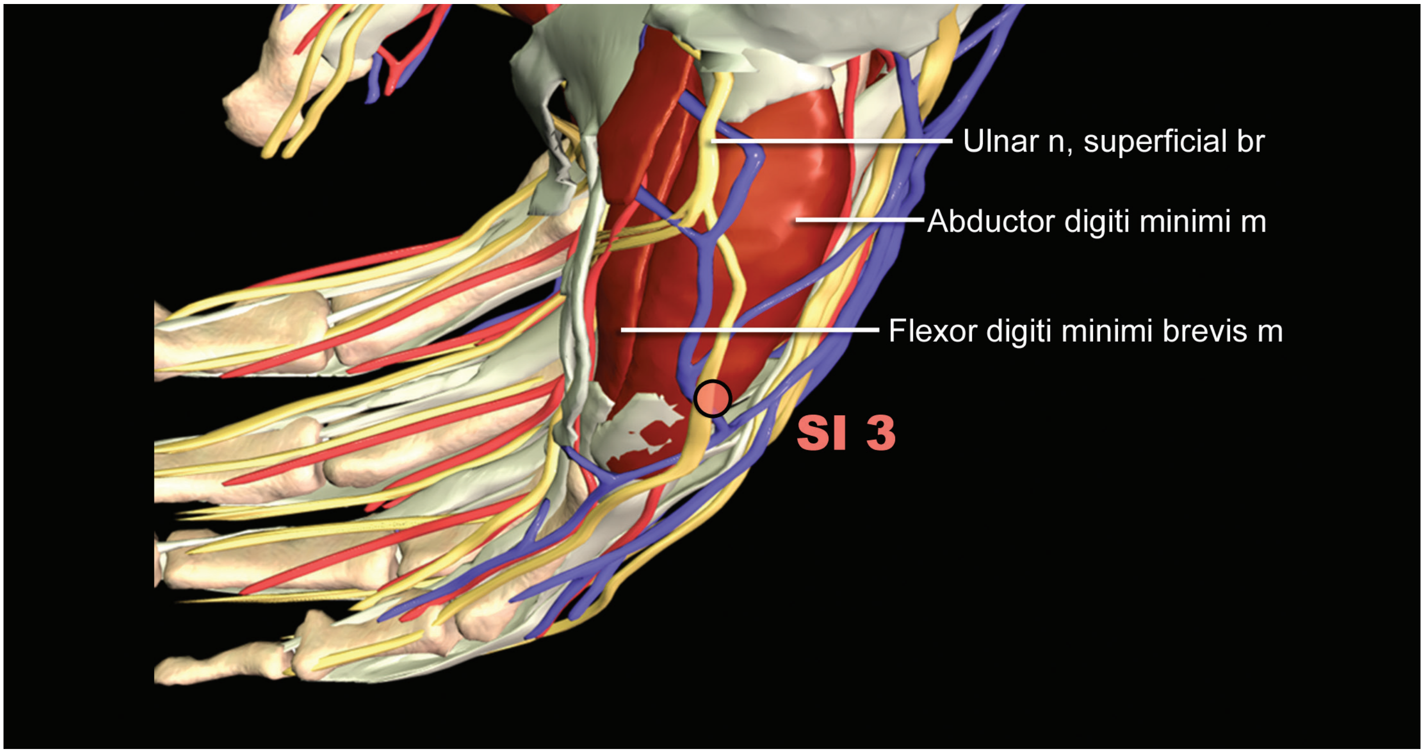

Figure 6-4. One of the strongest indications for SI 3 pertains to its effects on neck pain. Mechanisms involve neuromodulation of C8/T1 spinal cord segments through its input via the ulnar nerve.

Evidence-Based Applications

- Electroacupuncture applied to SI 3, BL 62, and four locations on the ear relating to the spinal cord contributed significantly to neurologic and functional recoveries in patients with **spinal cord injuries.**[2]
- Electroacupuncture at LI 4 and SI 3 produce significant changes in **skin temperature of the hand.**[3]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **dry eye, or KCS.**[4]
- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud's syndrome**, demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[5]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain**: KI 3, KI 10, SI 3, SI 18, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, and GB 44.[6]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[7]
- Acupuncture at SI 3 and Luo Zhen (M-UE-24; also called "dorsal PC 8" because it can be found on the dorsum of the hand on the other side of PC 8) alleviated neck pain in patients with **acute torticollis.**[11]

SI 4

Wan Gu "Wrist Bone"

On the ulnar side of the hand, in a depression between the pisiform bone and the base of the 5th metacarpal, at the dorsal/palmar skin junction.

Muscles

- **Abductor digiti minimi muscle of the hand:** Abducts the little finger (5th digit).
- **Flexor digiti minimi brevis muscle:** Flexes the proximal phalanx of the little finger.
- **Opponens digiti minimi muscle:** Allows the little finger to oppose the thumb.
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.

Clinical Relevance: Ulnar tunnel syndrome at the hand occurs usually as a result of ganglions, cysts, repetitive motion injury, bicycling, lipomas, and other activities in which the wrist is hyperextended for prolonged periods of time or during which continued pressure impacts the ulnar nerve in the hypothenar eminence. For those cases in which myofascial dysfunction is restricting nerve gliding and reducing circulation, acupuncture and related techniques relaxes the tissue, improves hemodynamics, and facilitates neural repair. The image in Figure 6-4 shows that aspect of the hand impacted by these activities or growths. The motor branch of the ulnar nerve inhabits the ulnar tunnel; the superficial (dorsal) branch is visible here traveling from SI 5 toward SI 1.

SI 4 coincides with the motor point of the abductor digiti minimi muscle.[1] Acupuncture and related techniques treat pain along the ulnar aspect of the hand due to myofascial restriction, whether at the motor point/central trigger point (SI 4) or the myotendinous junctions of the abductor digiti minimi muscle at SI 3 and SI 5.

Nerves

- **Common palmar digital branches of the superficial branch of the ulnar nerve:** Supply sympathetic motor innervation to the palmar and dorsal skin of the little finger and ulnar half of the ring finger.
- **Dorsal digital nerves:** Supply the ulnar aspect of the little finger, derived from the ulnar nerve.
- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger

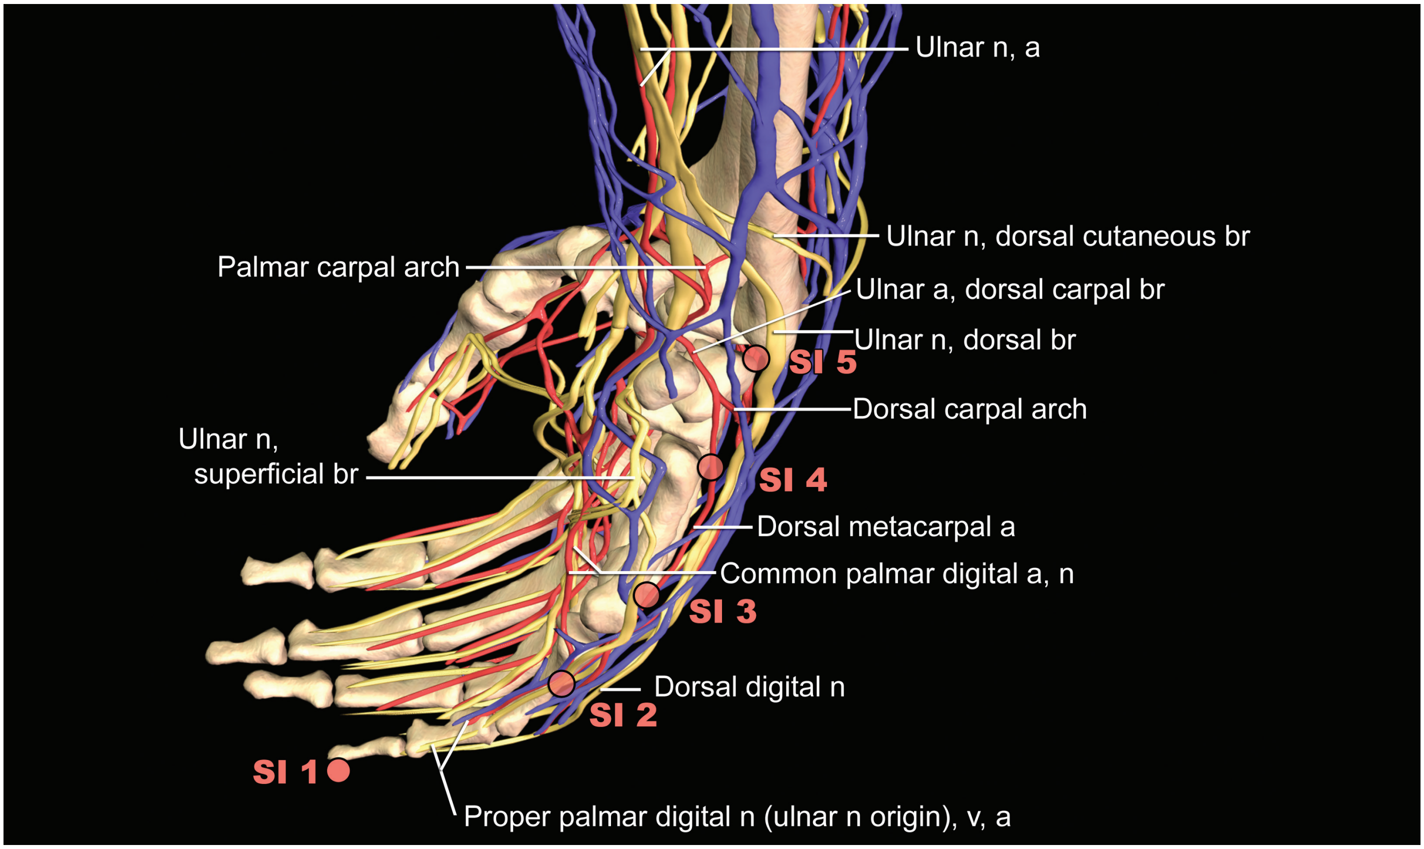

Figure 6-5. The descriptive name for SI 4, "Wrist Bone" refers to the bony juncture of the wrist and hand, comprising the intersection of the 4th metacarpal, ulna, and the pisiform bone.

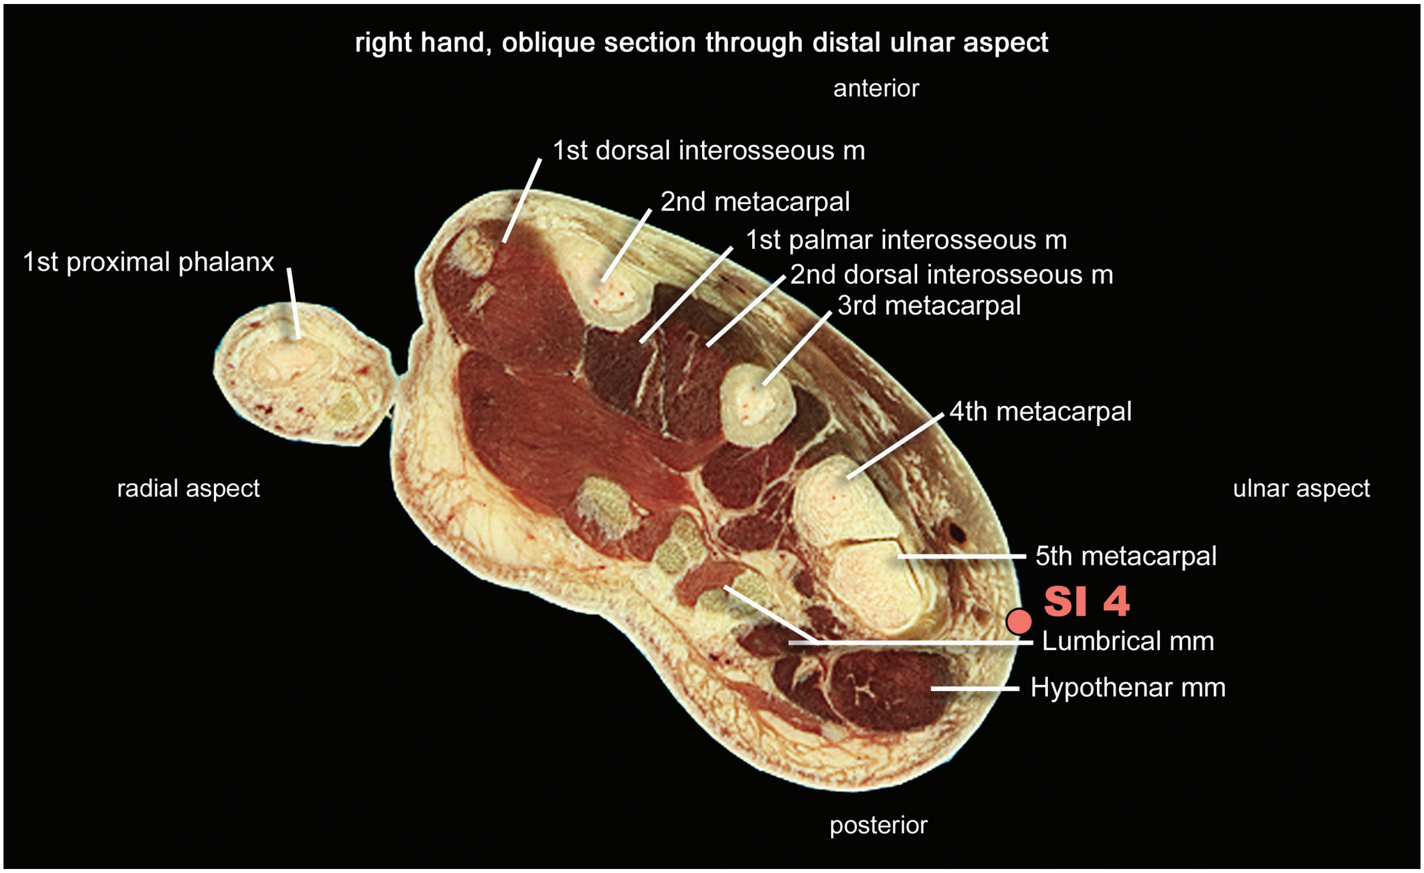

Figure 6-6. Cross sections such as this connect the layout of the underlying anatomy with the acupuncture point, indicating the insertion angle necessary to achieve clinical success, depending on the goal(s).

and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus, extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles.

Clinical Relevance: Guyon's canal syndrome, a compression neuropathy of the ulnar nerve in the wrist or hand, can cause loss of sensory, motor, or their combined functions.[2] Acupuncture treatment of Guyon's canal syndrome would likely require inputs directed toward points on both the HT and SI lines local to the wrist, hand, and elbow.

Vessels

- **Dorsal venous network:** Formed by the three dorsal metacarpal veins, which in turn arise from the dorsal digital veins. This portion of the dorsal venous network drains into the cephalic vein.
- **Superficial palmar arch:** This constitutes the main termination of the ulnar artery. The superficial palmar arch gives rise to three common palmar digital arteries. These arteries anastomose with the palmar metacarpal arteries, which arise from the deep palmar arterial arch. In contrast to the superficial palmar arch which arises mainly from the ulnar artery, the radial artery provides the main arterial basis for the deep palmar arch.
- **Deep branch of the ulnar artery:** Anastomoses with the radial artery to complete the deep palmar arch.
- Common palmar digital artery for 4th and 5th digits: Each common palmar digital artery divides into proper palmar digital arteries, which give rise to a dorsal branch innervating the finger tips with vessels known as the dorsal branches of the proper palmar digital arteries. The proper palmar digital arteries course along the adjacent sides of digits II through IV.
- **Common palmar digital veins for 4th and 5th digits:** The superficial and deep palmar venous arches accompany the superficial and deep palmar arterial arches.

Clinical Relevance: Figure 6-5 shows the anatomical relationship between SI 4 and underlying vessels, including the dorsal carpal arterial arch, the dorsal metacarpal artery, and associated venous networks. Treating this region with acupuncture, massage, and/or laser therapy would improve circulation in the ulnar aspect of the wrist. Better blood flow brings oxygen, nutrients, and supportive xenobiotics to the region to aid in tissue repair and maintenance.

Indications and Potential Point Combinations

- **Shoulder, neck, elbow, headache, or temporomandibular joint (TMJ) pain related to the SI channel distribution:** SI 4 (or SI 3; the anatomy overlaps), adding local points neuroanatomically related to the pain, spinal segmental points neuroanatomically related to the pain, and myofascial trigger points as found.

For shoulder pain, add relevant tender trigger points over the scapula. For neck pain along the SI line, examine the sternocleidomastoid muscle and additional potentially restricted zones extending to the clavicle and trapezius muscle. For head pain referring to the vertex, palpate BL points on the head (especially BL 7 and BL 8) and neck (BL 10); consider adding GV 20 if heat present. For TMJ pain, add tender myofascial trigger points over the shoulder and neck, as well as SI 18 and SI 19.

- **Local wrist pain:** SI 4 if pain localizes to the ulnar aspect of the wrist. Localize source of pain if possible; closely examine the flexor carpi ulnaris muscle which may radiate pain to the SI 4, SI 5 region.

SI 5

Yang Gu "Yang Valley"

On the ulnar side of the wrist, in the depression between the ulnar styloid process, the triquetrum, and the pisiform bone.

Connective Tissues

- **Extensor retinaculum:** Holds the extensor tendons of the wrist in place.

Clinical Relevance: Myofascial dysfunction involving the extensor retinaculum at the wrist may cause compression of ulnar nerve branches, seen in Figure 6-7 coursing beneath the structure on the palmar and dorsal aspects of the wrist. Acupuncture and related techniques directed toward SI 5 and nearby points aid in alleviating tissue compression in this tightly contained region, i.e., the wrist.

Muscles

- **Extensor carpi ulnaris tendon:** Extends and adducts the hand at the wrist.
- **Flexor carpi ulnaris tendon:** Flexes and adducts the hand at the wrist.
- **Pronator quadratus muscle:** Binds together the ulna and radius; pronates the antebrachium.

Clinical Relevance: SI 5 resides in a region imbued with both flexor and extensor attachments. Repetitive motions of the wrist such as computer work with a mouse, and compressive forces generated by tasks like bicycle riding can cause pain and debility in the wrist.

Nerves

- **Ulnar nerve (C8-T1):** The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the extensor carpi ulnaris muscle as well as others leading to the hand.
- **Anterior interosseous nerve (from the median nerve (C8, T1)):**

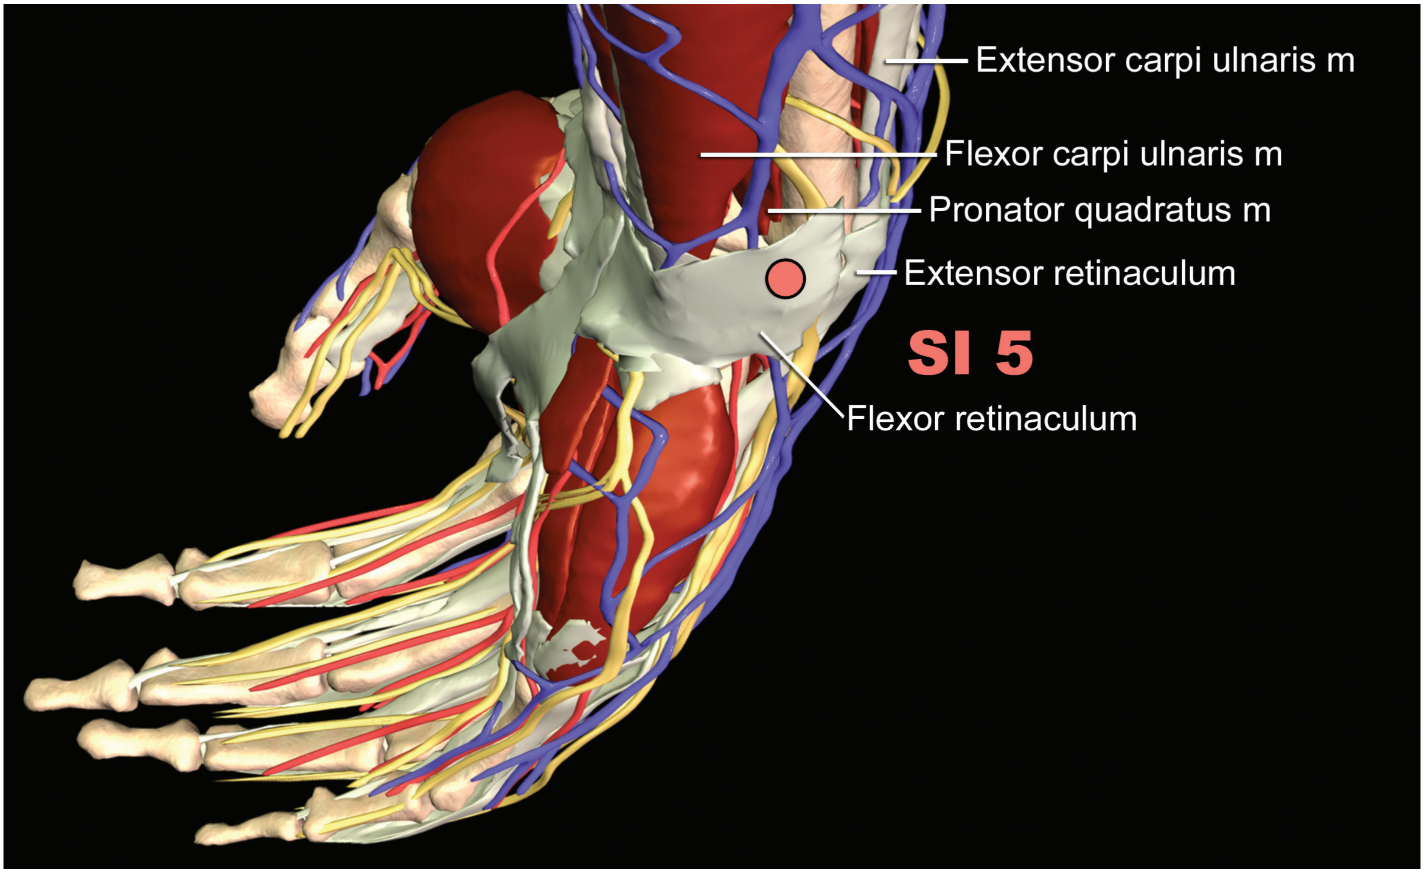

Figure 6-7. SI 5, "Yang Valley", rests in a nook ("valley") along the ulnar (Yang) surface of the wrist.

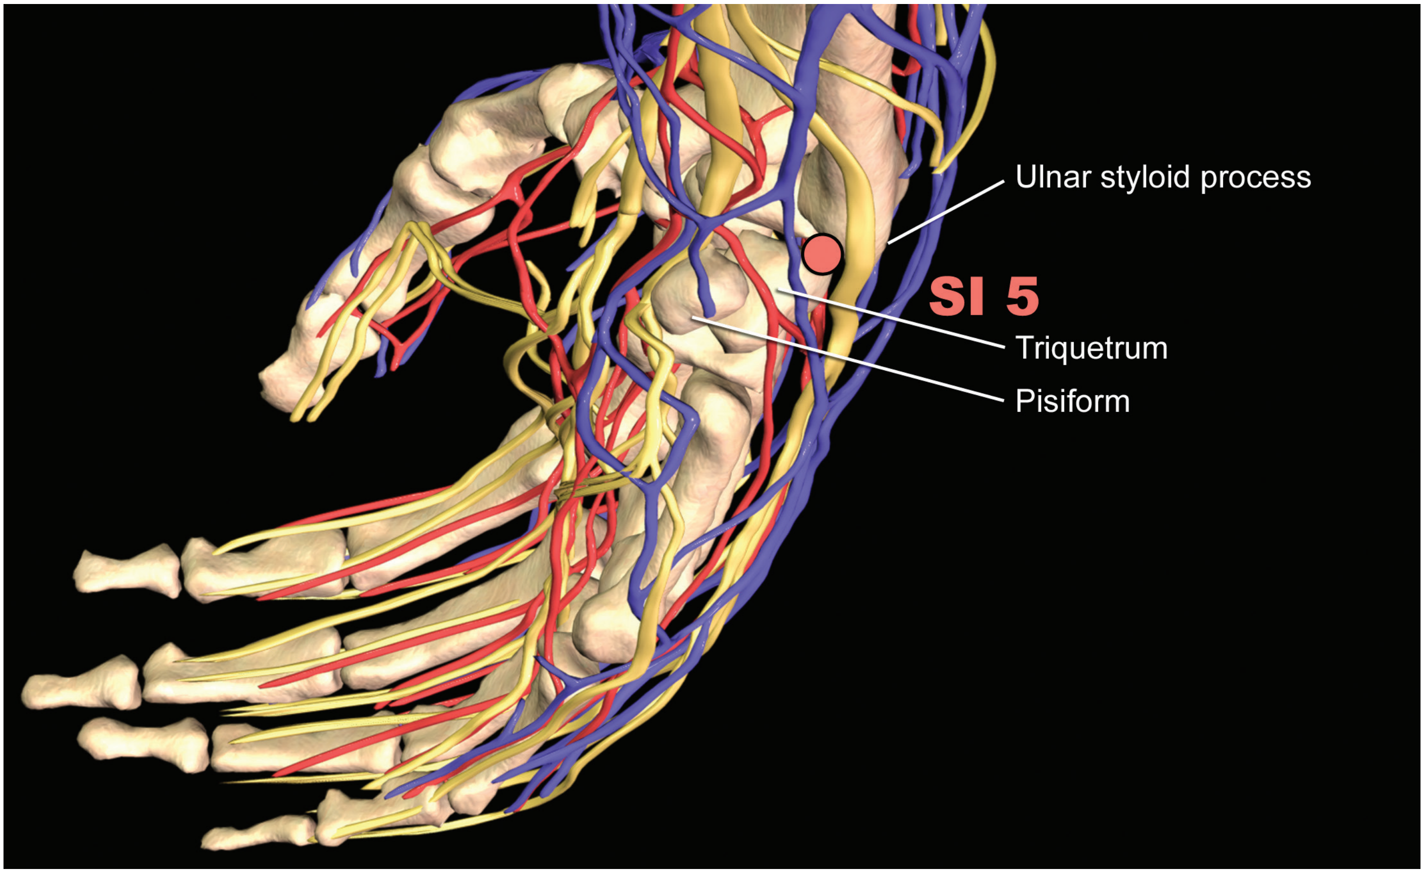

Figure 6-8. SI 5 as "Yang Valley" is bounded by the pisiform bone, triquetrum, and the ulnar styloid process. The point is often tender to palpation, more likely to be so than SI 1 to SI 4, considering the range of motion and mechanical strain affecting this location.

Supplies the pronator quadratus muscle.

Clinical Relevance: Guyon's canal syndrome, a compression neuropathy of the ulnar nerve in the wrist or hand, can cause loss of sensory, motor, or their combined functions.[1] Acupuncture treatment of Guyon's canal syndrome would likely require inputs directed toward points on both the HT and SI lines local to the wrist, hand, and elbow.

Vessels

- **Deep branch of the ulnar artery:** Anastomoses with the radial artery to complete the deep palmar arch.
- **Dorsal carpal branch of the ulnar artery:** Arises from the ulnar artery at the wrist. Anastomoses with branches of the radial artery, thereby providing collateral circulation for the wrist joint via dorsal and palmar carpal arches.
- **Paired ulnar veins:** Accompany the ulnar artery. Anastomose readily with paired veins accompanying the radial artery.
- **Basilic vein:** The basilic vein courses along the medial aspect of the arm and ultimately empties into the axillary vein after merging with the brachial veins. The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm. At the elbow, it joins the median cubital vein.

Clinical Relevance: Acupuncture at SI 5 will improve blood flow through the vessels inhabiting the ulnocarpal joint seen in Figure 6-8.

Indications and Potential Point Combinations

- **Agitation:** SI 5, HT 7, and KI 3
- **Wrist pain:** SI 5 if tender. Explore for trigger points in the flexor carpi ulnaris muscle.

References

1. Ozdemir O, Calisaneller T, Gulsen S, et al. Ulnar nerve entrapment in Guyon's canal due to recurrent carpal tunnel syndrome: case report. *Turkish Neurosurgery.* 2011;21(3):435-437.

SI 6

Yang Lao "Support the Aged"

Proximal to the wrist, in a dorsal depression proximal to the radial aspect of the head of the ulna.

Alternate method of location: When the patient's palm faces the chest, the point sits in the cleft on the radial aspect of the high point of the ulnar styloid process when the wrist is flexed and the index finger points to the sternum.

Muscles

- **Extensor carpi ulnaris tendon:** Extends and adducts the hand at the wrist. Its musculotendinous unit confers both agonist and antagonist action in wrist motion, imparting the act of throwing darts, for example.[1] Forceful wrist supination, flexion, or ulnar deviation can rupture the extensor carpi ulnaris tendon sheath, a connective tissue structure that stabilizes the tendon inside a groove along the distal ulna. Patients who complain of a painful snapping or clicking sensation over the dorsoulnar wrist during antebrachial rotation could be experiencing extensor carpi ulnaris instability. Asking the patient to simulate the action of scooping ice cream with the involved hand against examiner resistance and palpation accentuates tendon subluxation and allows identification of subtle instabilities.[2]
- **Extensor digiti minimi muscle:** Extends the little finger at both the metacarpophalangeal and interphalangeal joints.
- **Extensor digitorum muscle:** The chief extensor of the medial four digits. Extends the digits at the metacarpophalangeal joints and extends the hand at the wrist.

Clinical Relevance: Athletes and musicians develop wrist pathologies, myofascial strain syndromes, and nerve entrapments as a consequence of specific overuse disorders.[3] Palpation and in-depth history taking should help identify the sources and consequences of pain and restriction, indicating where and how to treat the condition with acupuncture and related techniques.

Carpal stability depends upon the shapes of bones interacting at the wrist as well as the intrinsic and extrinsic ligaments and muscles crossing the joint.[4] The neuromuscular system controls joint stability through a sophisticated network of proprioceptive orchestration. Considering the impact of the extensor carpi ulnaris on stability of the distal radioulnar joint, conservative (i.e., non-surgical) treatment of carpal instability should target tendons that cross the joint and retrain proprioceptive control.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1), ulnar branch:** Arises from the medial cord of the brachial plexus.
- **Posterior cutaneous nerve of the forearm (C5-C8):** A branch of the radial nerve that supplies the skin on the posterior surface of the antebrachium.
- **Posterior interosseous nerve (C7, C8):** A continuation of the deep branch of the radial nerve. Innervates the abductor pollicis longus, extensor pollicis brevis, extensor pollicis longus,

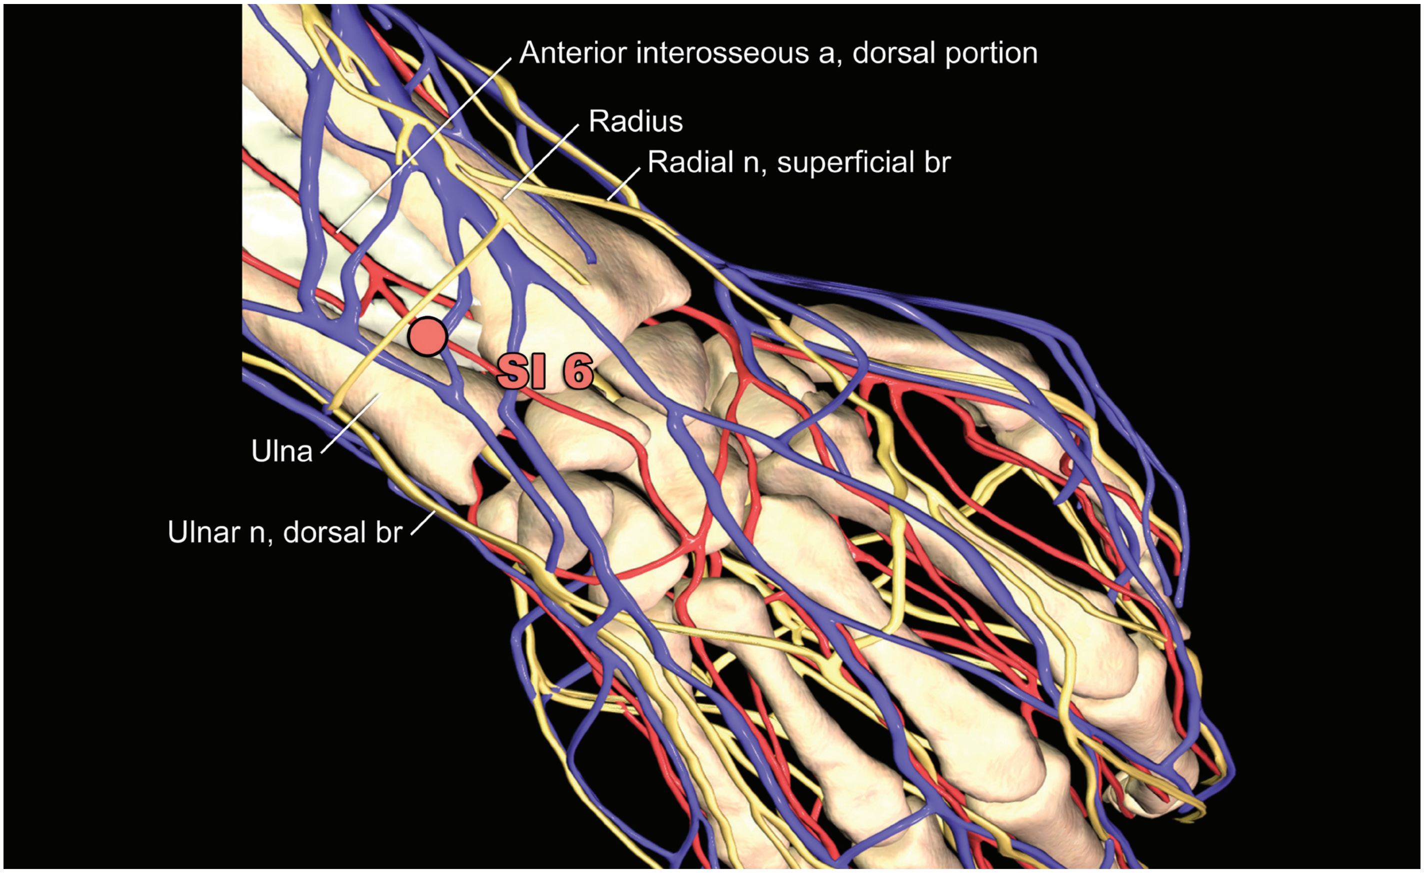

Figure 6-9. SI 6 sits atop a high-traffic neurovascular section of the wrist. This image also shows a connecting branch between the ulnar and radial nerves. Although the posterior interosseous nerve is not shown, it follows the course of the artery atop the interosseous membrane.

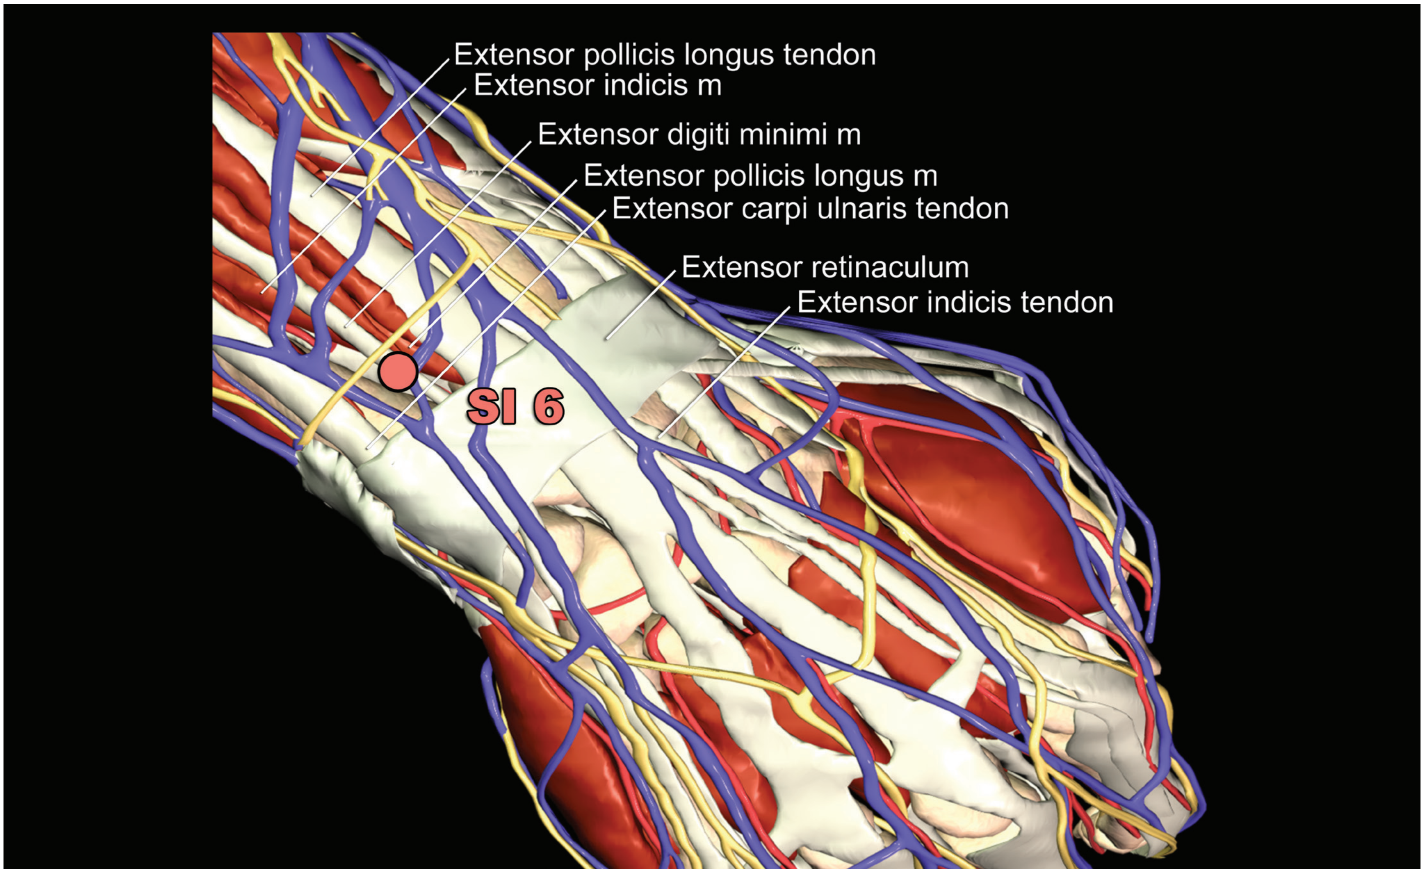

Figure 6-10. SI 6, "Nursing the Aged", lands where elderly exhibit tremor. The name for SI 6 conjures the image of an elderly woman sitting with her elbow resting on the arm of her chair and her fingers pointing to her chest, making the depression where SI 6 lands more visible. This typical posture may come about because contractures, weakness, or arthritis have led to shortening of the flexor tendons of the wrist, causing the wrist to assume this position of ease. Note how the extensor carpi ulnaris tendon stands apart from the bulk of other tendons coursing within its own sheath. It contributes substantial dynamic stability to the carpus along with the distal radioulnar joint.

extensor indicis, extensor digitorum, extensor digiti minimi, and extensor carpi ulnaris muscles.

Clinical Relevance: Although acupuncture needling is often employed to support nerve recovery and alleviate entrapment, cases exist of nerve injury following acupuncture. If a needle traumatizes a vessel wall, a resulting hematoma could cause neural compression. In addition, a fractured needle tip can irritate or otherwise injure a nerve. In some cases, the needle may lead to a nerve laceration. Relevant to SI 6, posterior interosseous nerve palsy has been reported following needle acupuncture.[5]

Vessels

- **Basilic vein:** The basilic vein courses along the medial aspect of the arm and ultimately empties into the axillary vein after merging with the brachial veins. The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm. At the elbow, it joins the median cubital vein.
- **Posterior and anterior interosseous arteries:** Both the anterior and posterior interosseous arteries arise from the common interosseous artery, which branches off of the ulnar artery. Both interosseous arteries course along the interosseous membrane. The posterior interosseous artery gives rise to the recurrent interosseous artery, which participates in the anastomoses around the elbow joint. The anterior interosseous artery supplies both sides of the interosseous membrane by providing a dorsal branch that emerges through the distal posterior portion of the interosseous membrane.
- **Posterior interosseous vein:** These deep veins accompany the interosseous arteries. The drain into the veins accompanying the radial and ulnar arteries.

Clinical Relevance: Figure 6-9 depicts the rich neurovascular supply of the underlying region. Acupuncture and related techniques improve local circulation which supports tissue healing and maintenance.

Indications and Potential Point Combinations

- **Pain along the SI channel in the mid-thoracic region, posterior shoulder, posteromedial arm, or medial elbow along the SI channel distribution:** SI 6 as a distal point, plus check for trigger points in the latissiumus dorsi, supraspinatus, infraspinatus, teres minor, teres major, subscapularis, and deltoid muscles. Consider SI 9, SI 10, SI 11, SI 12, SI 13, SI 14.
- **Eye diseases:** blurred vision, conjunctivitis: SI 6, BL 1, TH 23, ST 36.
- **Occipital headache:** SI 6, plus examine sternocleidomastoid muscle for trigger points, consider SI 16, TH 16, GB 20, BL 10, GV 20.

SI 7

Zhi Zheng "Branch of the Correct"

On the ulnar aspect of the antebrachium, 5 cun proximal to the wrist joint, on a line joining SI 5 and SI 8, between the ventral border of the ulna and the flexor carpi ulnaris muscle belly.

Muscles

- **Flexor carpi ulnaris muscle:** Adducts and flexes the hand at the wrist. The flexor carpi ulnaris contains two heads, between which the ulnar nerve courses in the distal portion of the forearm. One head attaches to the humerus, and the other to the ulna.
- **Flexor digitorum profundus muscle:** Flexes the distal phalanges at the distal interphalangeal joints of the fingers. Aids flexion of the hand.

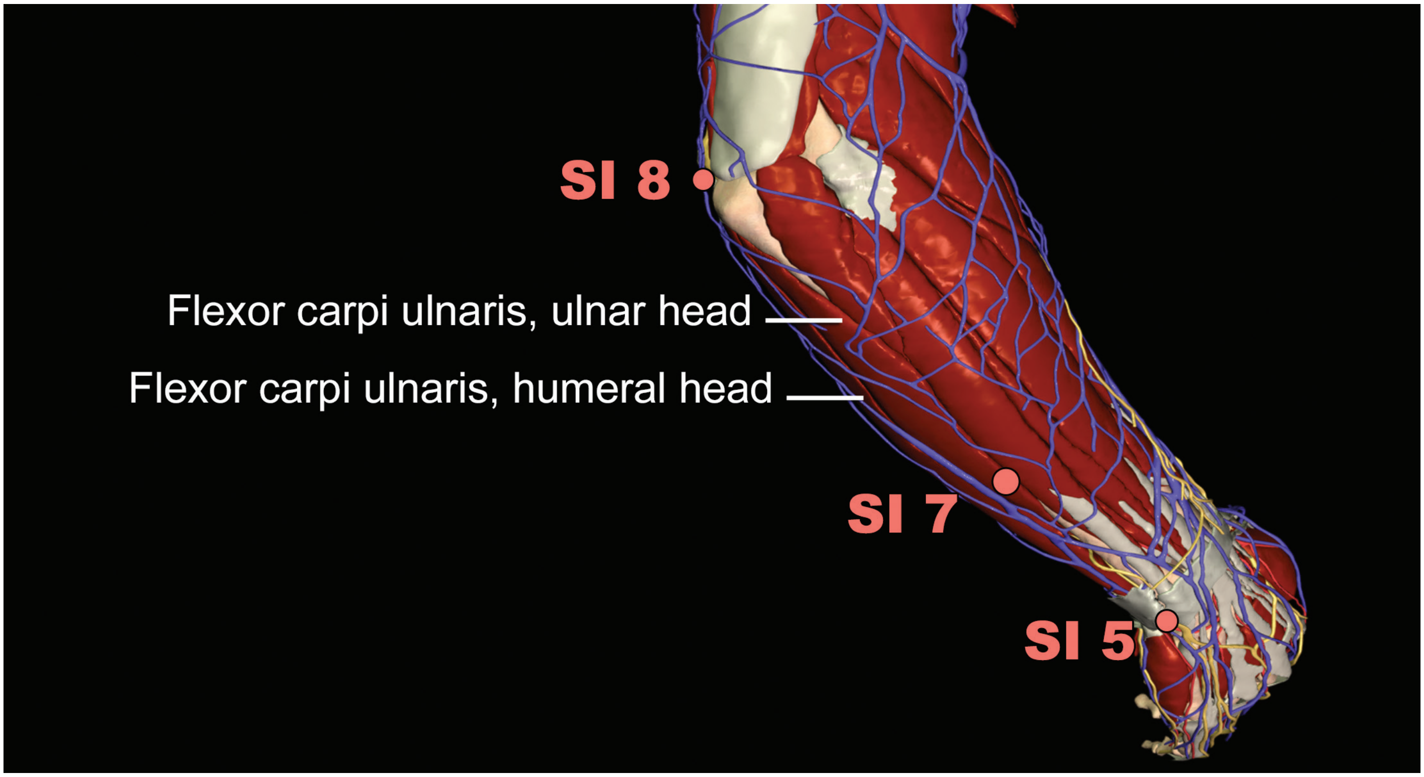
Clinical Relevance: Myofascial dysfunction affecting muscles within reach of SI 7 (i.e., the flexor carpi ulnaris, flexor digitorum superficialis, and flexor digitorum profundus) may collectively compress the ulnar nerve and vessels coursing between them. The cross section shown in Figure 6-14 illustrates these relationships. Muscles impacted by needling at SI 7 will vary according to the direction and depth of needling. Trigger point pathology in the flexor carpi ulnaris muscle refers pain strongly to the ulnar aspect of the wrist along the HT channel (HT 5-HT 7). Acupuncture needling can reproduce referred pain stemming from myofascial trigger points, reaffirming site selection.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Ulnar nerve (C8-T1):** Arises as a terminal branch of the medial cord of the brachial plexus, receiving fibers from C8, T1, and often C7. It courses down the medial aspect of the arm and provides articular branches to the elbow joint. At the elbow, it continues posterior to the medial epicondyle and enters the antebrachium (forearm).

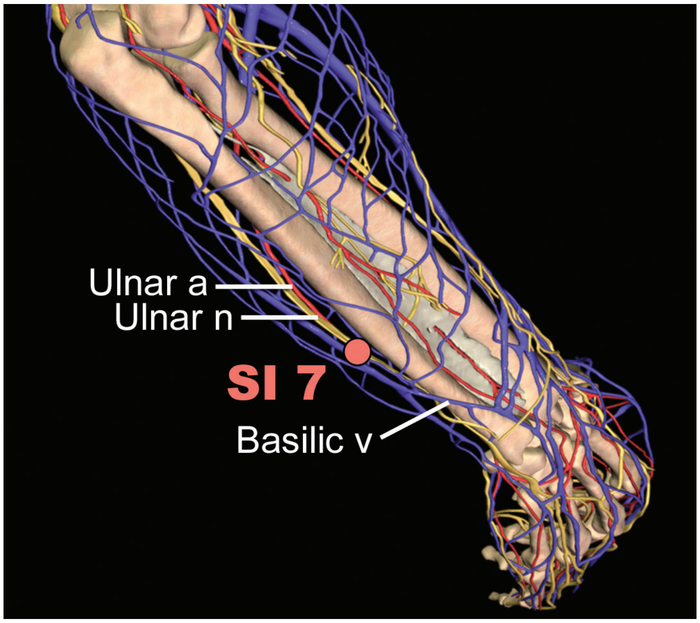
Clinical Relevance: Both the medial antebrachial cutaneous and ulnar nerves are susceptible to injury by dint of their position on the ulnar surface of the antebrachium where blunt force against the bone can injure the nerves. In addition, phlebotomy hasa been reported to damage the nerve, albeit rarely, causing paresthesia and forearm pain.[2] Acupuncture and related techniques would support nerve healing and provide analgesia to the area. Note the position of the ulnar nerve in relation to the bone in Figure 6-13.

Another source of nerve injury relates to subluxation-related ulnar neuropathy resulting from dorsal radioulnar joint instability. In this condition, antebrachial rotation produces a sensory deficit, ordinarily following a history of trauma to the wrist or forearm.[3] Paresthesias become most severe in the maximally pronated position; motor symptoms are infrequent. If patients do complain of motor difficulty, the problem has likely become chronic. Stabilization reduces neurologic injury. Acupuncture applied to SI 7 and nearby regions can reduce myofascial dysfunction impacting the nerves.



SI 8
Flexor carpi ulnaris, ulnar head
Flexor carpi ulnaris, humeral head
SI 7
SI 5

Figure 6-12. SI 7 begins the SI channel's migration from the extensor surface of the thoracic limb at SI 6 to the flexor aspect from SI 7 to SI 8. As such, SI 7 engages include predominantly flexors. The tunnel between SI 7 and SI 8 corresponds to the cubital tunnel that houses the ulnar nerve. The myofascial cleavage plane between the ulnar and humeral heads of the flexor carpi ulnaris describes the course of the ulnar nerve where compression commonly occurs. A fibrous brand from the medial intermuscular septum may cross the ulnar nerve to compress it further. Myofascial restriction in the flexor carpi ulnaris, flexor digitorum profundus, and flexor digitorum superficialis can contribute to the problem.



Ulnar a
Ulnar n
SI 7
Basilic v

Figure 6-13. The name, "Branch to the Correct" for SI 7 refers to the deviation of the SI channel toward the HT line's territory along the antebrachium, i.e., the ulnar neurovasculature. In addition, "Branch to the Correct" connotes the way in which the radius overrides the ulna during pronation, as tree limbs might cross. The ulna, however, leads to the HT and SI channels while the radius takes one to the LU and LI lines.

Vessels

- **Basilic vein:** The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm.
- **Ulnar artery:** Arises near the neck of the radius in the cubital fossa. It provides several branches, including the anterior and posterior (branches of the) ulnar recurrent arteries, the common interosseous artery, the anterior and posterior interosseous arteries, and the dorsal and palmar carpal branches, which anastomose with the radial artery.
- **Ulnar veins:** These paired veins drain the forearm and accompany the ulnar artery. They receive tributaries from muscles lying nearby.

Clinical Relevance: Figure 6-14 depicts the proximity of SI 7 to the basilic vein. Figure 6-13 illustrates how the basilic vein joins SI 6 to SI 7, corresponding to the original vascular basis of acupuncture. Acupuncturists treating patients after shoulder surgery or arthroscopy should be vigilant for pain and swelling in the thoracic limb that can reflect deep venous thrombosis in the axillary, basilic, and brachial veins.[4]

Figure 6-14. This cross section illustrates how SI 7 "straddles the fence" that separates the flexor and extensor surfaces of the forearm. It denotes the location where the SI line travels from the dorsal to the palmar surface of the forearm.

Indications and Potential Point Combinations

- **Forearm or elbow pain:** Select SI 7 if tender. Isolate which, if any, muscles are generating the pain. Needle the central trigger points in the endplate zones of the muscles and assess for associated enthesopathy expressed as attachment trigger points.
- **Inability to grasp with hand:** Identify neural dysfunction and treat accordingly. If ulnar neuropathy, target SI 7 plus SI 6 and HT 7. Consider cervical spinal nerve points in caudal cervical region to address spinal nerve roots supplying the ulnar nerve.
- **Ulnar neuralgia:** Consider ulnar nerve entrapment in the cubital tunnel. This tunnel constitutes a narrow passageway bordered laterally by the elbow joint, medially by the two heads (humeral and ulnar) of the flexor carpi ulnaris muscle, and anteriorly by the medial epicondyle of the humerus.

SI 8

Xiao Hai "Small Sea"

On the posteromedial elbow, over the ulnar groove (also known as the humeral sulcus for the ulnar nerve), in the depression between the medial epicondyle of the humerus and the olecranon. Locate with the elbow slightly flexed.

Caution with needling to avoid traumatizing the vulnerable ulnar Nerve at SI 8.

Nerves

- **Medial antebrachial cutaneous nerve (C8, T1):** Supplies the skin on the anterior and medial aspects of the forearm.
- **Ulnar nerve (C8-T1):** Arises as a terminal branch of the medial cord of the brachial plexus, receiving fibers from C8, T1, and often C7. It courses down the medial aspect of the arm and provides articular branches to the elbow joint. At the elbow, it continues posterior to the medial epicondyle and enters the antebrachium (forearm). The ulnar nerve supplies the flexor carpi ulnaris and ulnar half of the flexor digitorum profundus muscle, which sends tendons to the 4th and 5th digits. The ulnar nerve supplies most of the intrinsic hand muscles (i.e., the hypothenar, interosseous, adductor pollicis, deep head of the flexor pollicis brevis, and the medial (IV and V) lumbrical muscles. It provides sensation to the palmar and distal dorsal aspects of the ulnar 1.5 digits (i.e., the little and the ulnar half of the ring finger) and adjacent palmar region. It gives off four branches: the palmar cutaneous, dorsal, superficial, and deep branches. The palmar cutaneous branch supplies the skin at overlying the carpal bones on the ulnar side of the wrist. The dorsal branch supplies the skin on the ulnar aspect of the dorsal hand and the proximal parts of the little and medial ring finger. The superficial branch supplies the palmaris brevis muscle, as well as sensation to the skin of the palmar and distal dorsal aspects of the little finger and the ulnar side of the ring finger, as well as the proximal palm. The deep branch supplies the hypothenar muscles (i.e., the abductor, flexor, and opponens digiti minimi), and the IV and V lumbrical muscles, the adductor pollicis muscle, and the deep head of the flexor pollicis brevis muscle.

Clinical Relevance: Entrapment of the ulnar nerve typically occurs at four sites: the arcade of Struthers (medial intermuscular septum), the ulnar groove, the cubital tunnel (humeroulnar arcade), and the exit point between the two heads of the flexor carpi ulnaris.[1] Compressive neuropathy of the ulnar nerve at the elbow is one of the most common nerve compressions of the thoracic limb.[2] Figure 6-15 reveals the abundance of muscular and connective tissue elements that might contribute to compression. An aponeurosis may form between the flexor digitorum superficialis and the flexor carpi ulnaris muscles, entrapping the nerve. Motor and/or sensory abnormalities can develop over the ulnar aspect of the forearm and hand. Flexion of the elbow increases intraneural pressure six-fold.[3] The size of the canal through which the ulnar nerve travels narrows by more than half as the oval passageway becomes elliptical. Cubitus valgus deformity, whether acquired or congenital, increases the likelihood of ulnar neuropathy. Athletes may acquire ulnar neuropathy after repeated valgus stress at the elbow. Sports putting the nerve at risk include baseball, javelin throwing, tennis, gymnastics, and football.[4] Acupuncture, manual therapy, laser therapy, and stretching can contribute to conservative management to alleviate myofascial restriction compressing the nerve. SI 8 would constitute the primary treatment focus.

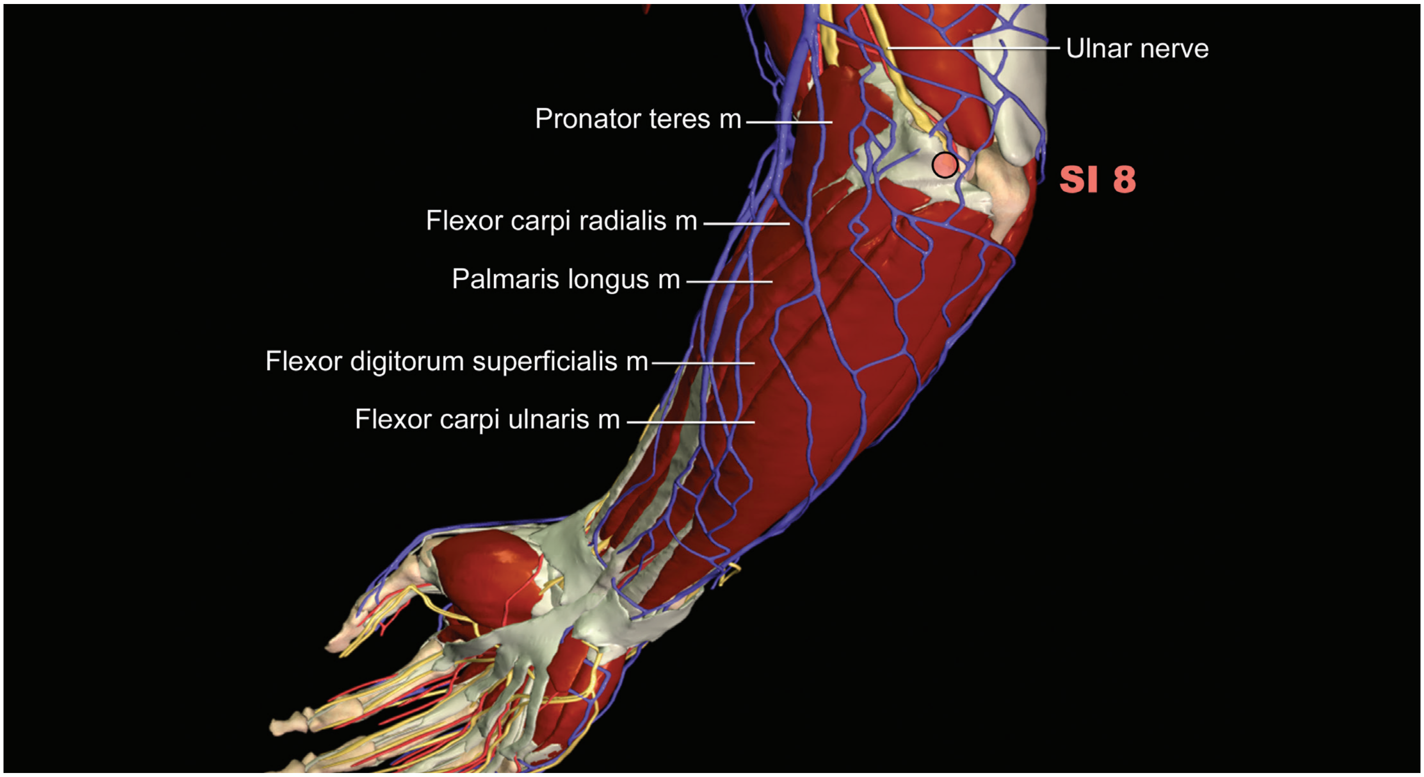

Figure 6-15. SI 8 sits directly over the ulnar nerve in the ulnar groove, vulnerable to compression and traction.

Vessels

- **Basilic vein:** The basilic vein courses along the medial aspect of the arm and ultimately empties into the axillary vein after merging with the brachial veins. The basilic vein arises from the medial aspect of the dorsal venous network of the hand and ascends along the posteromedial forearm. At the elbow, it joins the median cubital vein.
- **Superior ulnar collateral artery:** This artery arises from the brachial artery near the middle of the arm and travels with the ulnar nerve toward the humerus. It anastomoses with the posterior branch of the ulnar recurrent artery and inferior ulnar collateral artery which participate in the elbow anastomoses.
- **Posterior (branch of the) ulnar recurrent artery:** Arises from the ulnar artery just past the elbow joint. It joins with the ulnar collateral and interosseous recurrent arteries to form the elbow anastomoses. It supplies the adjacent muscles.
- **Inferior ulnar collateral artery:** This artery arises from the brachial artery about 5 cm proximal to the cubital crease. It joins the elbow anastomoses via its connection with the anterior branch of the ulnar recurrent artery.

Clinical Relevance: Despite the abundant anastomoses around the elbow, arterial injuries at the elbow have a high risk of causing muscle necrosis.[5] Elbow trauma leading to fracture and requiring orthopedic fixation may injure the brachial artery and cause ischemic injury to the hand.[6] Elbow dislocations, in particular, run the risk of concomitant periarticular neurovascular

Figure 6-17. The ulnar groove and its neural content shown beneath SI 8 are what people commonly refer to as the "funny bone" due to the uncomfortable, tingly feeling experienced when the elbow hits the corner of a table or similar object.

injury. The arterial and venous anatomoses surrounding the elbow appear in Figure 6-16.

Indications and Potential Point Combinations

- **Medial epicondylitis:** SI 8, not needled deeply. Examine proximal and distal to the elbow for trigger points and tender enthesiopathies.
- **Pain or stiffness along the SI channel:** Aside from myofascial strain leading to or accentuating ulnar nerve entrapment and thereby making the case for treating SI 8, selecting other points along the SI channel that associate with more myofascial tissue and less risk of injuring the nerve seems more prudent.

SI 9

Jian Zhen "True Shoulder", "Central Shoulder"

On the dorsal shoulder, 1 cun cranial to the end of the start of the axillary fold (see channel drawing at beginning of this chapter, in a depression caudal to the infraglenoid tubercle (see Figure 6-19), lateral to the lateral border of the scapula. The point occurs along the caudal border of the deltoid muscle.

The point relates closely to the quadrangular space (see Figure 6-18).

Muscles

- **Deltoid muscle:** The posterior part extends the arm and rotates it laterally. The anterior part flexes the arm and rotates it medially. The middle part abducts the arm.
- **Teres minor muscle:** Adducts the arm and rotates it medially. The teres minor tendon crosses and unites with the caudal shoulder joint capsule.

Clinical Relevance: Axillary neuropathy in cases of quadrilateral space syndrome or other sources of injury to the axillary nerve may cause pain and weakness in the shoulder and be mistaken for rotator cuff syndrome.[1] However, patients with denervation of the teres minor muscle due to axillary neuropathy differs from rotator cuff syndrome in that patients may have no history of trauma or show display torn tendons. Selective compression of the axillary nerve branch supplying the teres minor and/or compression of the posterior humeral circumflex artery can induce selective teres minor atrophy. Humeral head decentering caused by caudal glenoid wear secondary to osteoarthritis may also lead to isolated teres minor atrophy.

Causes of axillary nerve compression include fibrous bands in the quadrilateral/quadrangular space and space-occupying lesions such as caudal paralabral cysts, lipomas, and venous dilations. Differential diagnoses include cranial shoulder dislocation, humeral neck fracture, stretch injury of the brachial plexus, and thoracic inlet or outlet syndromes. Imaging and electrophysiologic studies assist in the diagnosis when physical examination and palpation cannot sufficiently delineate the cause of pain and/or weakness.

Myofascial pain syndrome in the shoulder warrants early intervention with acupuncture and/or related techniques in order to avert progression to rotator cuff tendinopathy, subacromial impingement syndrome, or other problems. SI 9 overlies the trigger point of the teres minor muscle; this site of somatic dysfunction refers pain strongly to the distal dorsal deltoid and dorsal proximal brachium.

Nerves

- **Axillary nerve (C5, C6):** Innervates the deltoid muscle and teres minor muscle. Also supplies the shoulder joint and the skin overlying the inferior deltoid region.

Clinical Relevance: The axillary nerve can suffer iatrogenic injury during orthopedic surgical procedures such as arthroscopy, thermal shrinkage of the shoulder capsule, and plate fixation of the proximal humerus.[2] Traumatic stretching or repetitive motion injury also has the potential to damage the nerve.

When the axillary nerve enters the quadrangular space, it divides into anterior and posterior branches that supply the deltoid, teres minor, and skin. The anterior branch provides

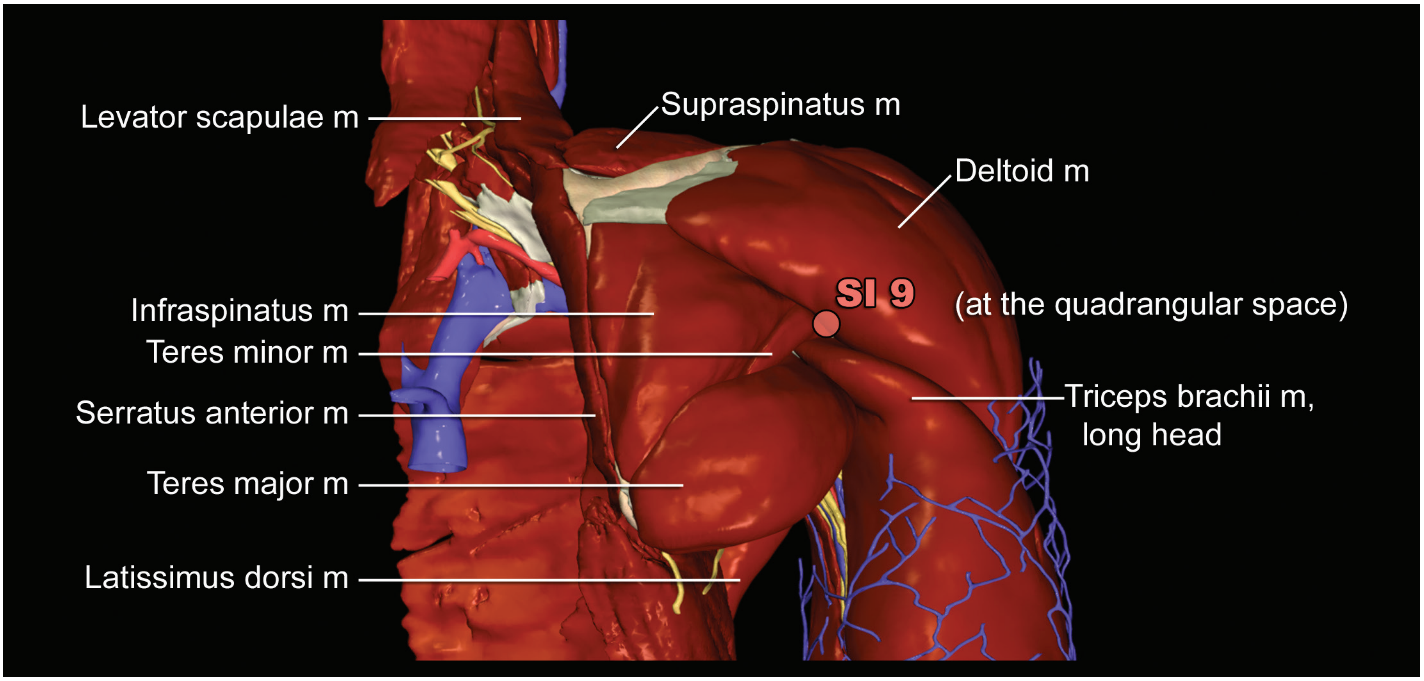

Figure 6-18. The "hole" one palpates at SI 9, identifies the quadrangular (quadrilateral) space, bordered by the long head of the triceps medially, the surgical neck of the humerus laterally, superiorly by the teres minor muscle, and inferiorly by the teres major muscle. The quadrangular space transmits the axillary nerve and posterior circumflex humeral artery. When compressed by the fibrous bands, myofascial restriction, or space-occupying lesions, the axillary nerve suffers entrapment, accompanied by a sensory deficit over the lateral shoulder and proximal dorsal brachium.[12] Relaxing muscle tension through acupuncture and related technique releases pressure on the nerve and accompanying artery.

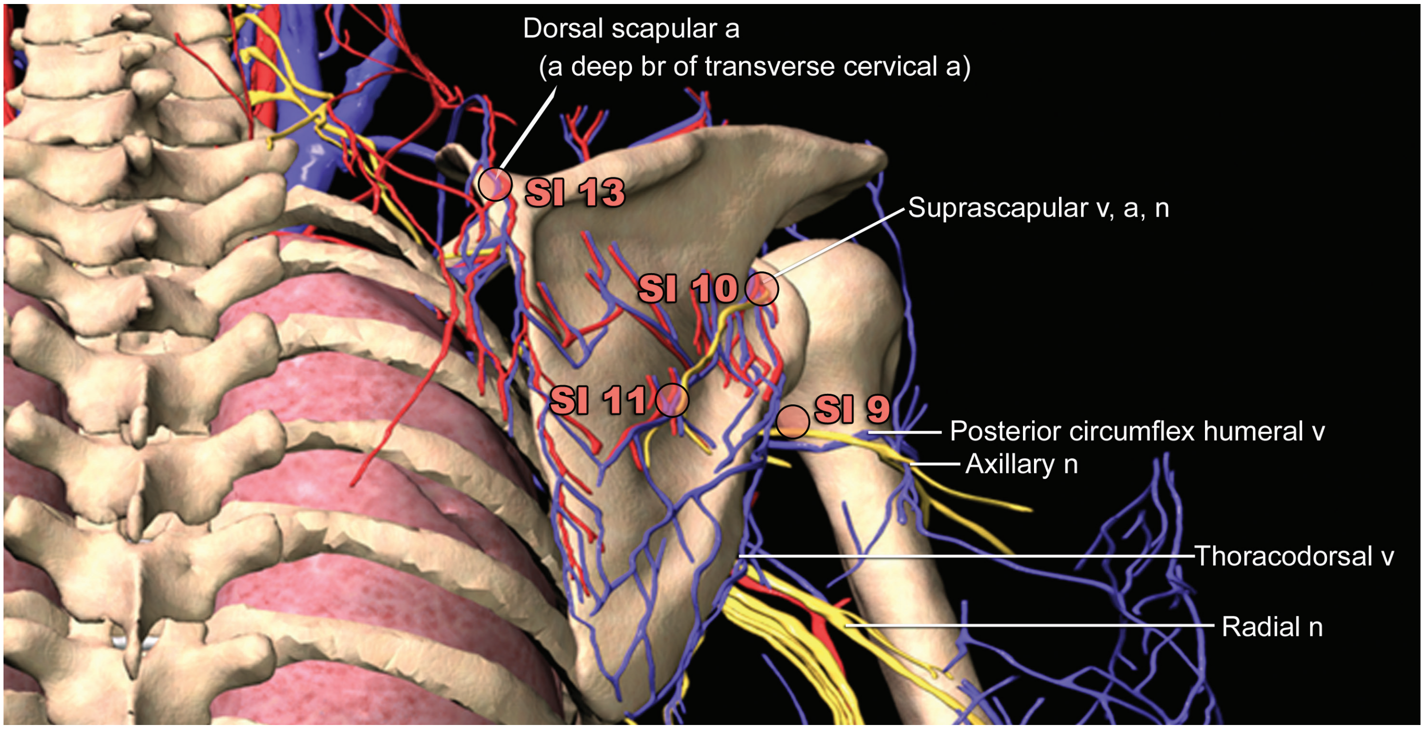

Figure 6-19. This neurovascular view of SI 9 explains its titles "True Shoulder" and "Central Shoulder". Its location over the axillary nerve and posterior circumflex humeral vessels appears as a hub at the joint around which the other SI points revolve.

branches to the joint capsule along with the anterior and middle deltoid heads. The teres minor muscle and deltoid muscle receive innervation from the posterior branch. Branching patterns often vary between individuals, raising the possibility of iatrogenic injury due to unpredictable courses of the nerves.

Glenohumeral arthrosis and associated humeral osteophytes may compress the axillary neurovascular bundle. A large, caudal humeral osteophyte known as a "goat's beard deformity" sometimes extends into the caudal portion of the glenohumeral joint capsule, potentially injuring the axillary nerve. Axillary nerve compression can then lead to fatty infiltration of the teres minor, evident on magnetic resonance imaging.[3]

Quadrilateral space syndrome involves compression of the posterior humeral circumflex artery and the axillary nerve by fibrotic bands that cross the space.[4] The quadrilateral space is the most common location of isolated compressive neuropathy of the axillary nerve.[5] Acute shoulder trauma and repetitive overuse as in baseball throwing are precursors to quadrilateral space syndrome.[6] Neuromodulation via acupuncture and related techniques may alleviate myofascial contributions to quadrangular (quadrilateral) space syndrome and improve nerve function in cases of axillary neuropathy.

Vessels

- **Posterior circumflex humeral artery:** Arises from the axillary artery and passes through the quadrangular space with the axillary nerve. Anastomoses with the anterior circumflex humeral artery to provide a circular anastomosis around the surgical neck of the humerus.
- **Posterior circumflex humeral vein:** Accompanies the posterior circumflex humeral artery.

Clinical Relevance: Dysfunction or trauma affecting the quadrangular space can injure the posterior circumflex humeral artery, leading to serious ischemic complications if misdiagnosed as a musculoskeletal problem.[7] Treatment targeting SI 9, SI 10, SI 11, and other local points can support tissue healing in conjunction with conventional approaches to vascular injury.

Indications and Potential Point Combinations

- **Pain or restricted movement of the shoulder or arm, chronic shoulder pain,[8] frozen shoulder:** SI 9 plus tender local trigger points.[9]
- **Rotator cuff tendinitis:** Palpate region and select points based on tenderness or other abnormalities; especially consider SI 9, SI 11, SI 12, LI 15, LI 14, TH 15, TH 14, BL 44, SI 14, and distal points including LI 11, SI 6, SI 3, TH 3, GB 34, and LU 2.[10]
- **Paresis or paralysis of the arm:** SI 9 if axillary involvement; as evidenced by weakness of deltoid, teres major and minor, and/or long head of the triceps muscles.
- **Brachial plexus injury:[11]** HT 1, SI 9, LI 4, LI 11, PC 6, caudal cervical spinal nerve sites.
- **Quadrangular (Quadrilateral) space syndrome:** SI 9, TH 13, LI 14; add laser therapy and massage.

SI 10

Nao Shu "Upper Arm Shu"

On the posterior aspect of the shoulder, In a depression inferior to the acromial end of the scapular spine, directly superior to SI 9 and the posterior axillary fold that appears when the arm is adducted.

Connective Tissues

- **Inferior transverse ligament (spinoglenoid ligament):** This weak, membranous band stretches from the lateral border of the scapular spine to the margin of the glenoid cavity. This ligament becomes an arch that covers the transverse scapular vessels and suprascapular nerve as it enters the infraspinous fossa.

Clinical Relevance: Ossification or hypertrophy of the inferior transverse ligament can narrow the notch through which the suprascapular nerve and vessels pass, predisposing these structures to compression and pathology. The inferior transverse ligament becomes taut during adduction and internal rotation of the thoracic limb, as happens in the follow-through phase of throwing.

Muscles

- **Deltoid muscle:** The posterior part extends the arm and rotates it laterally. The anterior part flexes the arm and rotates it medially. The middle part abducts the arm.
- **Infraspinatus muscle:** Rotates the arm laterally. Assists the teres minor muscle in keeping the humeral head within the glenoid cavity of the scapula.

Clinical Relevance: As shown in Figure 6-23, a needle entering SI 10 would first encounter the deltoid muscle, followed by the insertion of the infraspinatus muscle onto the greater tubercle of the humerus. SI 10 lands over the trigger point of the dorsal division of the deltoid. It refers pain strongly to the dorsal shoulder joint and proximal dorsal brachium.

Nerves

- **Axillary nerve (C5, C6):** Innervates the deltoid muscle and teres minor muscle. Supplies the shoulder joint and continues on as the superior lateral cutaneous nerve, innervating the skin overlying the inferior deltoid region.
- **Suprascapular nerve (C4-C6):** Supplies the supraspinatus and infraspinatus muscles.
- **Lateral supraclavicular nerve (C3, C4):** Supplies the skin over the shoulder.

Clinical Relevance: Figure 6-22 indicates the relationship between SI 10 and the suprascapular nerve. Depending on the site of entry of an acupuncture needle and the angle of its insertion, stimulation of SI 10 can impact suprascapular nerve function and circulation of the territory its accompanying vessels supply. As with the axillary nerve at SI 9, traction or compression can damage the suprascapular nerve at SI 10. More are recognizing suprascapular neuropathy as a source of shoulder pain and weakness, whether or not the patient has concomitant shoulder joint pathology.[1] Etiologies include repetitive overhead activity such as volleyball, baseball, tennis, basketball, swimming, painting the ceiling, etc. that places traction on the nerve. In addition, space-occupying lesions such as a ganglion cysts and lipomas as well as myofascial tension may compress the nerve. Retraction of a large rotator cuff tear contributes to

Figure 6-21. The structures traveling through SI 10, "Upper Arm Transport" include the infraspinatus tendon, the suprascapular nerve, and the circumflex scapular artery.

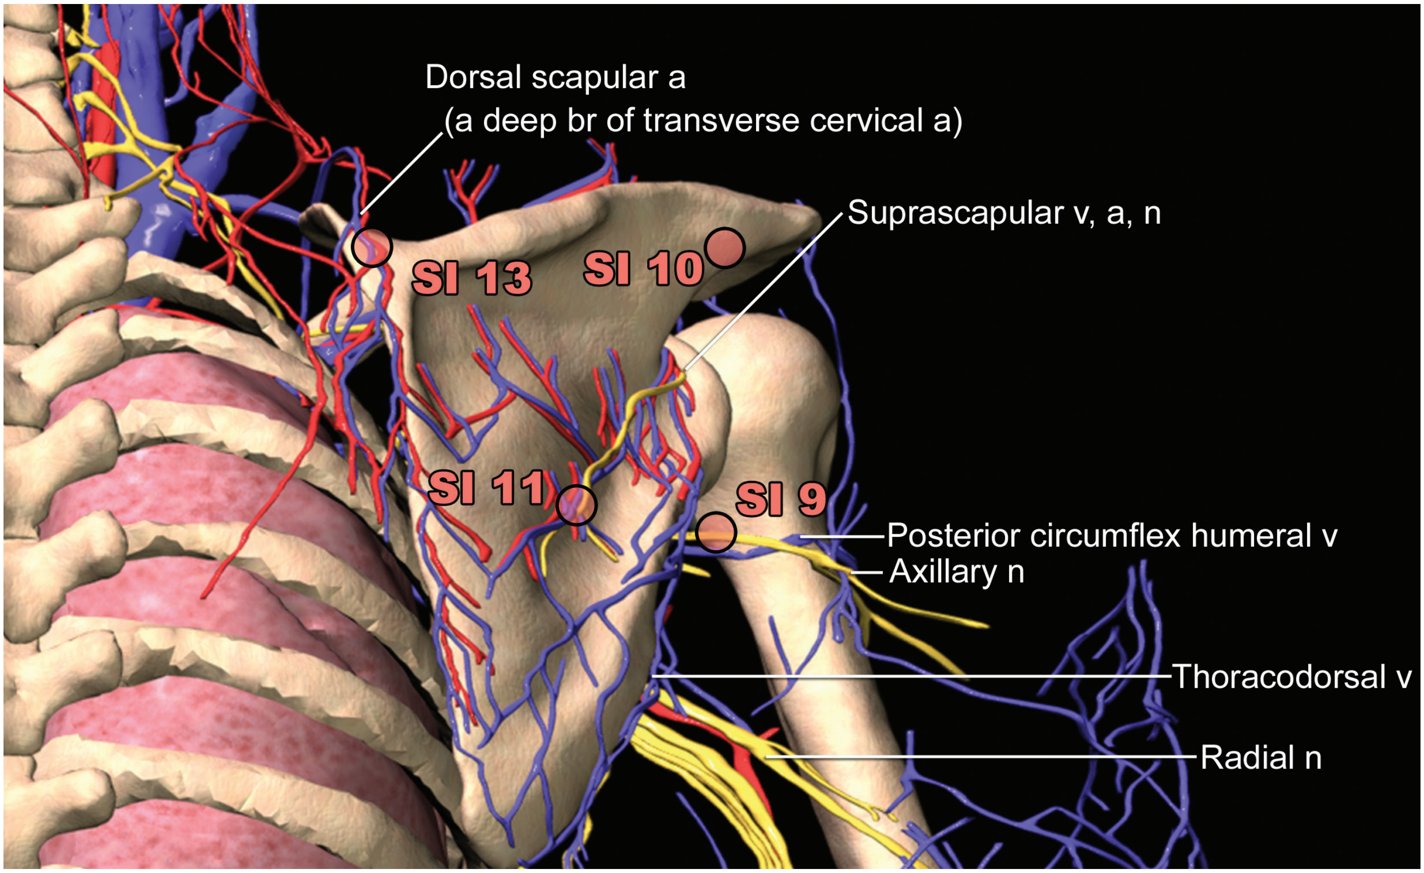

Figure 6-22. The company kept by SI 10 includes several other scapular SI points such as SI 9, SI 11, SI 12 (not shown), and SI 13 that typically cause the patient to report tenderness upon their palpation. This neurovascular layer exposes the rich scapular anastomotic network of vessels.

traction injury as the pull of the shortening infraspinatus muscle drags the suprascapular nerve in a medial direction against the suprascapular notch. Patients with suprascapular neuropathy may show marked infraspinatus muscle atrophy. Conservative treatment through physical therapy and neuromodulation, including acupuncture, are first-line approaches.

Vessels

- **Suprascapular artery:** Arises from the thyrocervical trunk (from the subclavian artery). Supplies the supraspinatus and infraspinatus muscles.
- **Suprascapular vein:** Accompanies the suprascapular artery. Empties into the external jugular vein.
- **Circumflex scapular artery:** This artery arises from the subscapular artery and reaches its destination to supply the muscles on the dorsum of the scapula by curving around the axillary border of the scapula. It takes part in the scapular anastomoses. Several vessels participate in the arterial anastomoses around the scapula, on both its anterior and posterior surfaces. These include the dorsal scapular, subscapular (via the circumflex scapular), and suprascapular arteries. These anastomoses create a potential collateral circulation pathway for the arm in the event of axillary artery obstruction or ligation.

Clinical Relevance: An "extremely intricate" vascular anastomosis surrounds the scapula.[2] The abundant vasculature provides for collateral circulation to the shoulder and scapula in the event of injury or acute blockade of the axillary artery. The circumflex scapular artery, appearing in Figure 6-22 between SI 10 and SI 9, is vulnerable to damage during a dorsal approach open reduction and internal fixation for scapular fracture. It encompasses the "at risk area" for the circumflex scapular artery where the ascending branch of the circumflex scapular artery anastomoses with the suprascapular artery.

Indications and Potential Point Combinations

- **Pain or weakness in the shoulder or arm:** Isolate cause (myofascial dysfunction, arthritis, neurologic impairment, etc.) and treat accordingly. SI 10 frequently appears in shoulder treatment protocols given its central placement on the posterior shoulder. near the joint.
- **Shoulder arthritis and pain:** SI 10, LI 15, TH 14, local trigger points.

SI 11

Tian Zong “Celestial Gathering”

In approximately the center of the infraspinous fossa in the belly of the infraspinatus muscle. Identify the site of maximal tenderness.

Muscles

- **Infraspinatus muscle:** Rotates the arm laterally. Assists the teres minor muscle in keeping the humeral head within the glenoid cavity of the scapula.

Clinical Relevance: Trigger points in the infraspinatus muscle, at SI 11 and surrounding sites refer strongly to the entire deltoid muscle and along the LU and LI channels. Manual therapy of active trigger points in the infraspinatus (SI 11), supraspinatus (SI 12), and subscapularis (dorsal to HT 1) significantly reduces spontaneous pain and tenderness to palpation in patients with shoulder impingement syndrome.[4]

The distribution of trigger point pathology in breast cancer patients following lumpectomy or mastectomy affects the infraspinatus, upper trapezius, sternocleidomastoid, levator scapulae, scalene, and pectoralis major muscles.[5] Widespread pain hypersensitivity and myofascial trigger points in the neck and shoulder in patients with postmastectomy pain develop as a result, at least in part, of peripheral and central sensitization.[6] Acupuncture and ischemic compression therapy reduce symptoms in patients with chronic shoulder pain of myofascial origin.[7,8]

Deactivation of trigger points in the infraspinatus (SI 11), supraspinatus (SI 12), gluteus and piriformis muscles lessened pain and discomfort associated with interstitial cystitis and pelvic pain.[9]

Nerves

- **Spinal nerves T2-T5:** Innervate the skin.
- **Suprascapular nerve (C4-C6):** Supplies the supraspinatus and infraspinatus muscles.

Clinical Relevance: Figure 6-22 indicates the relationship between SI 10 and the suprascapular nerve. Depending on the site of entry of an acupuncture needle and the angle of its insertion, stimulation of SI 10 can impact suprascapular nerve function and circulation of the territory its accompanying vessels supply. As with the axillary nerve at SI 9, traction or compression can damage the suprascapular nerve at SI 10. More are recognizing suprascapular neuropathy as a source of shoulder pain and weakness, whether or not the patient has concomitant shoulder joint pathology.[10] Etiologies include repetitive overhead activity such as volleyball, baseball, tennis, basketball, swimming, painting the ceiling, etc. that places traction on the nerve. In addition, space-occupying lesions such as a ganglion cysts and lipomas as well as myofascial tension may compress the nerve. Retraction of a large rotator cuff tear contributes to traction injury as the pull of the shortening infraspinatus muscle drags the suprascapular nerve in a medial direction against the suprascapular notch. Patients with suprascapular neuropathy may show marked infraspinatus muscle atrophy. Conservative treatment through physical therapy and neuromodulation, including acupuncture, are first-line approaches.

The relationship of SI 11 to lactation[11] can be explained through dermatomal overlap at the level of the spinal cord and neuroendocrine effects from reducing sympathetic facilitation.[12]

Vessels

- **Suprascapular artery:** Arises from the thyrocervical trunk (from the subclavian artery). Supplies the supraspinatus and infraspinatus muscles.
- **Suprascapular vein:** Accompanies the suprascapular artery. Empties into the external jugular vein.
- **Circumflex scapular artery:** This artery arises from the subscapular artery and reaches its destination to supply the

muscles on the dorsum of the scapula by curving around the axillary border of the scapula. It takes part in the scapular anastomoses. Several vessels participate in the arterial anastomoses around the scapula, on both its anterior and posterior surfaces. These include the dorsal scapular, subscapular (via the circumflex scapular), and suprascapular arteries. These anastomoses create a potential collateral circulation pathway for the arm in the event of axillary artery obstruction or ligation.

Clinical Relevance: An "extremely intricate" vascular anastomosis surrounds the scapula.[13] The abundant vasculature provides for collateral circulation to the shoulder and scapula in the event of injury or acute blockade of the axillary artery. The location of SI 11 in the middle of the infraspinatus (also known as infraspinous) fossa seen in Figure 6-22 denotes not only the neural but also the vascular underpinning of SI 11. Trigger point deactivation involves not only nerve stimulation and dysfunctional motor endplate disruption, but also improvement of tissue perfusion and oxygen tension. Thus, stimulation of SI 11 needs to affect both the suprascapular nerve and its similarly named vessels in order to successfully resolve infraspinatus dysfunction.

Indications and Potential Point Combinations

- **Shoulder and arm pain made worse by applying pressure to the infraspinatus muscle:** SI 11; add associated trigger points in the anterior deltoid, supraspinatus muscle, biceps brachii, teres major, and latissimus dorsi muscles. In addition, Travell and Simon suggest palpating the subscapularis and pectoralis major muscles for myofascial trigger points.[1] Treat bilaterally even with unilateral shoulder and arm pain due to the role of central sensitization in maintaining and accruing further trigger points.[2,3]
- **Lactation disorders:** SI 11, SI 1, LI 4.[14]

SI 12

Bing Feng "Grasping the Wind"

In approximately in the center of the supraspinous fossa, directly above SI 11, in a depression that appears in the belly of the supraspinatus muscle when the arm is abducted.

Muscles

- **Trapezius muscle:** Acts on the scapula to elevate, retract, and rotate it.
- **Supraspinatus muscle:** Helps the deltoid muscle abducts the arm and initiates the abduction movement. Acts as a rotator cuff muscle along with the infraspinatus, teres minor, and subscapularis muscles.

Clinical Relevance: Myofascial trigger points in the supraspinatus muscle at and around SI 12 send pain referral patterns along the LI territory to the wrist, with pain accentuated at the deltoid and lateral elbow. Depressed individuals appear to harbor more latent trigger points in the trapezius, supraspinatus, serratus anterior, and rhomboid muscles than non-depressed people do.[1]

Nerves

- **Spinal nerves T2-T5:** Innervate the skin.
- **Supraclavicular nerve (C3, C4), lateral branches:** Supplies the skin over the shoulder

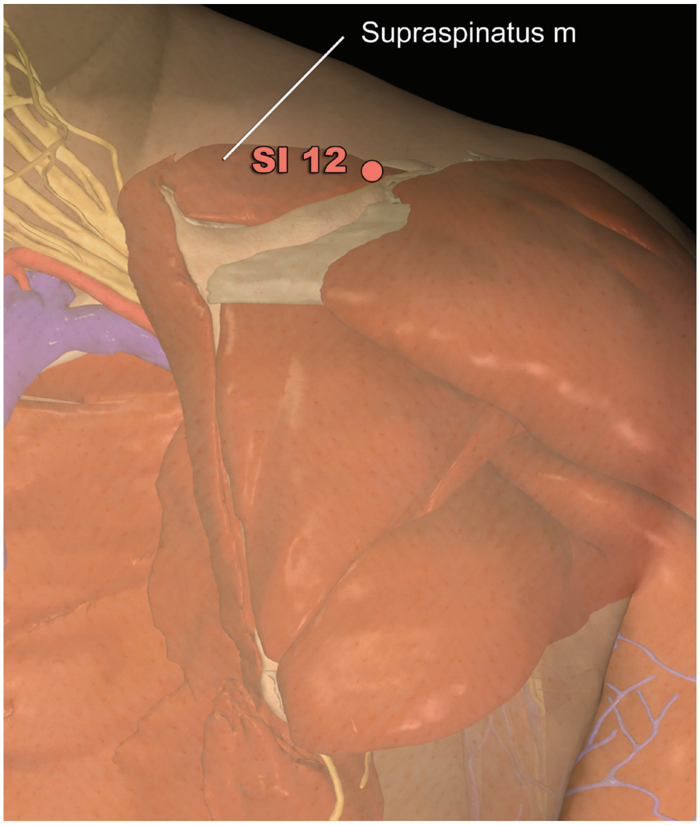

Figure 6-25. SI 12 resides in the center of the supraspinatus fossa. This image illustrates how the fossa curves around the shoulder, causing the supraspinatus muscle to become more horizontal than the infraspinatus.

- **Spinal accessory nerve (also known as the spinal root of the accessory nerve):** Provides motor function to the trapezius.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.
- **Suprascapular nerve (C4-C6):** Supplies the supraspinatus and infraspinatus muscles.

Clinical Relevance: The suprascapular nerve as it enters the supraspinatus fossa travels to a tunnel where it may suffer compression at three locations. Connective tissue places pressure on the nerve at the cranial and caudal incisurae or deep to fascia between the incisurae, creating a tunnel syndrome of entrapment for the suprascapular nerve. Acupuncture and related techniques designed to target the sources of this entrapment would need to treat the relevant, and deep, compressive structures.

Vessels

- **Suprascapular artery:** Arises from the thyrocervical trunk (from the subclavian artery). Supplies the supraspinatus and infraspinatus muscles.
- **Suprascapular vein:** Accompanies the suprascapular artery. Empties into the external jugular vein.

Clinical Relevance: Trigger point deactivation of SI 12 in the supraspinous fossa improves local blood flow and tissue oxygenation through the suprascapular vessels.

Indications and Potential Point Combinations

- **Stiffness or pain of the shoulder, especially as related to supraspinatus muscle trigger points, leading to a deep ache in the shoulder that may radiate to the lateral epicondyle of the humerus (LI 11) or even to the wrist (LI line):** SI 12, LI 15, TH 14, LI 11, SI 8.
- **Shoulder-arm syndrome (cervicothoracic brachialgia):**[3] SI 12, GB 21, relevant trigger points, consider SI 16, LI 14, TH 13, LI 11, LI 4.

Qu Yuan "Crooked Wall"

In a depression dorsal to the medial end of the scapular spine at the medial limit of the supraspinous fossa. Occurs midway between SI 10 and the T2 spinous process as shown in Figure 6-22. Can be found by sliding a fingertip in a medial direction along the dorsal aspect of the scapular spine; the fingertip will land in a tender depression just lateral to the medial border of the scapula.

Muscles

- **Trapezius muscle:** Acts on the scapula to elevate, retract, and rotate it.
- **Supraspinatus muscle:** Helps the deltoid muscle abducts the arm and initiates the abduction movement. Acts as a rotator cuff muscle along with the infraspinatus, teres minor, and subscapularis muscles.

Clinical Relevance: Myofascial trigger points in the supraspinatus muscle at and around SI 12 and SI 13 send pain referral patterns along the LI territory to the wrist, with pain accentuated at the deltoid and lateral elbow. Depressed individuals appear to harbor more latent trigger points in the trapezius, supraspinatus, serratus anterior, and rhomboid muscles than non-depressed people do.[1]

Compare the location of SI 12 in the center of the supraspinatus muscle with SI 13 which, though unlabeled, would sit just lateral to the bony border between the levator scapulae muscle and the supraspinatus. The trapezius muscle's bulk mounts at SI 13. Thus, a needle entering SI 13 would affect both the trapezius and the supraspinatus muscles.

Nerves

- **Spinal nerves T1-T3:** Innervate the skin.
- **Spinal accessory nerve (also known as the spinal root of the accessory nerve):** Provides motor function to the trapezius.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.
- **Suprascapular nerve (C4-C6):** Supplies the supraspinatus and infraspinatus muscles.

Clinical Relevance: The suprascapular nerve as it enters the supraspinatus fossa travels to a tunnel where it may suffer compression at three locations.[2] Connective tissue places pressure on the nerve at the cranial and caudal incisurae or deep to fascia between the incisurae, creating a tunnel syndrome of entrapment for the suprascapular nerve. Acupuncture and related techniques designed to target the sources of this entrapment would need to treat the relevant, and deep, compressive structures.

Vessels

- **Suprascapular artery:** Arises from the thyrocervical trunk (from the subclavian artery). Supplies the supraspinatus and infraspinatus muscles.
- **Suprascapular vein:** Accompanies the suprascapular artery. Empties into the external jugular vein.
- **Transverse cervical artery:** Arises from the thyrocervical trunk, along with the suprascapular artery, to supply the muscles in the posterior cervical triangle, the trapezius, and the medial scapular muscles. After crossing the phrenic nerve and anterior scalene muscle, superior to the clavicle, the transverse cervical artery then courses through the trunks of the brachial plexus.

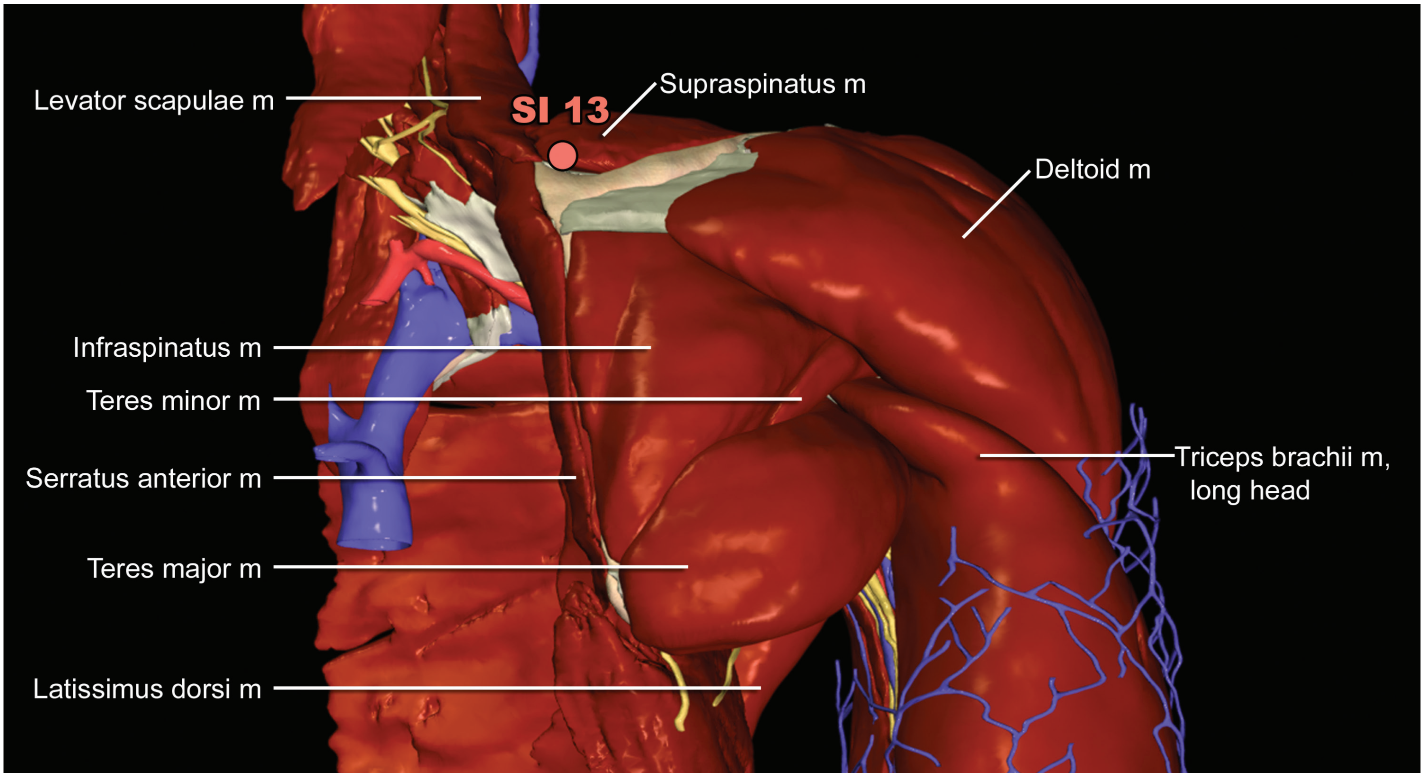

Figure 6-27. Myofascial trigger points fill the fossae of the scapula. Both SI 13 and SI 12 treat these supraspinatus trigger points.

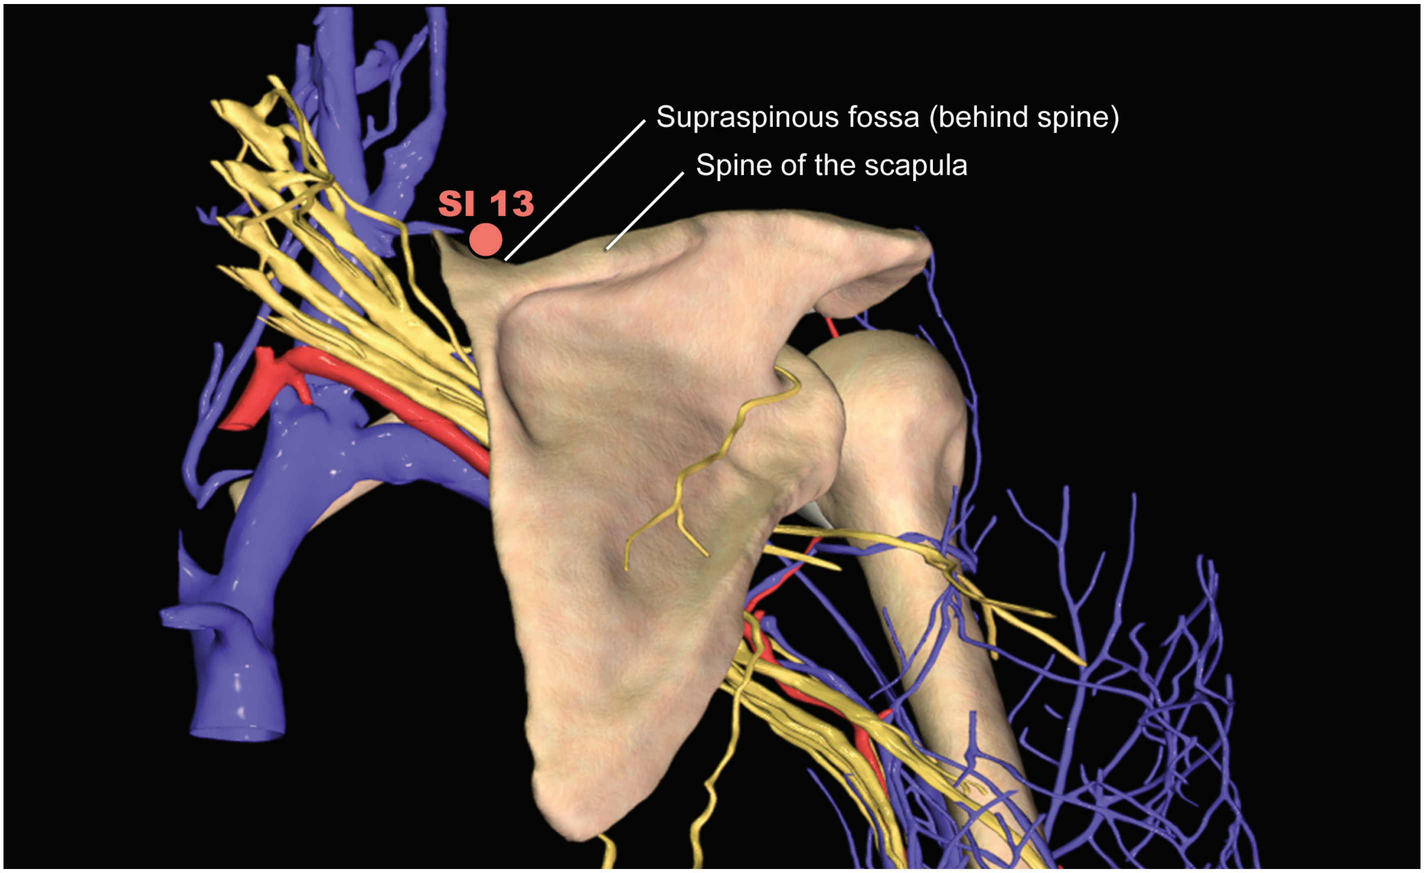

Figure 6-28. The name "Crooked Wall" for SI 13 refers to the uneven border of the medial angle of the scapula, shown in relation to other scapular SI points in Figure 6-22.

As it does so, it supplies branches to the vasa nervorum of the plexus. The dorsal scapular artery may branch from the transverse cervical artery, but it occasionally arises from the subclavian artery.

Clinical Relevance: Trigger point deactivation of SI 13 in the supraspinous fossa improves local blood flow and tissue oxygenation through the suprascapular vessels and the deep branch of the transverse cervical artery.

Indications and Potential Point Combinations

- **Shoulder pain or dysfunction, tension in the upper back:** SI 13 plus local trigger points, add BL 10 for neck pain.

SI 14

Jian Wai Shu
"Outer Shoulder Transport"

Approximately 3 cun lateral to the dorsal midline, level with GV 13 (at the caudal border of the spinous process of T1), just medial and slightly caudal to the medial angle of the scapula, usually located 3 cun lateral to the midline.

Caution needling this point. Whereas the bony scapula would ordinarily stop an acupuncture needle at SI 11, SI 12, and SI 13 from entering the lungs, SI 14 lines up with the outer Bladder channel. As such, it lands over lung fields and specifically the cervical pleura, also known as the cupula of the pleura.

Muscles

- **Trapezius muscle:** Acts on the scapula to elevate, retract, and rotate it.
- **Levator scapulae muscle:** Tilts the glenoid cavity of the scapula inferiorly while rotating and elevating the scapula.
- **Rhomboid minor muscle:** Affixes the scapula against the thoracic wall. Rotates the scapula and retracts it, resulting in causing the glenoid cavity of the scapula to move in an inferior direction.

Clinical Relevance: Figure 6-30 exposes how an acupuncture needle entering SI 14 encounters the trapezius, rhomboid minor, and levator scapulae muscle, depending on needling depth. SI 13, SI 14, and SI 15 reside in a region customarily rich with myofascial trigger points. The cross section appearing in Figure 6-30 reveals the multilayered musculature at and around SI 14, presenting multiple opportunities for pain relief.

Trigger points in the trapezius near SI 14 propel pain toward GV 14 along the paraspinal region inhabited by BL 11, shown in Figure 6-29.

Levator scapulae trigger points focus pain strongly in the angle between the neck and shoulder. Pain from the levator scapulae muscle extends to the dorsal shoulder and medial scapular border, in rhomboid territory.

Rhomboid pain centralizes over the muscles themselves and emanates diffusely across the scapular region.

Nerves

- **Spinal nerves C8-T1:** Innervate the skin.
- **Spinal accessory nerve (also known as the spinal root of the accessory nerve):** Provides motor function to the trapezius.
- **Spinal nerves C2, C3, and C4:** Carry pain and proprioceptive information from the trapezius and sternocleidomastoid muscles.
- **Dorsal scapular nerve (C5, with contributions from C4-T1[2]):** Innervates the levator scapulae and rhomboid major and minor muscles.

Clinical Relevance: Dorsal scapular nerve injury from trauma presents as a sharp pain in the shoulder while lifting heavy objects overhead.[3] Mechanism of injury includes traction or compression of the nerve through extended overhead work. Lifting a heavy box overhead places the dorsal scapular nerve at risk, as do occupational activities (for painters, electricians, dry wallers, etc.) involving raising the arms for long periods of time. Hypertrophy of the middle scalene muscle can lead to dorsal scapular nerve entrapment. Pain arises from strain in compensatory or parascapular muscles or spasm in antagonists of the

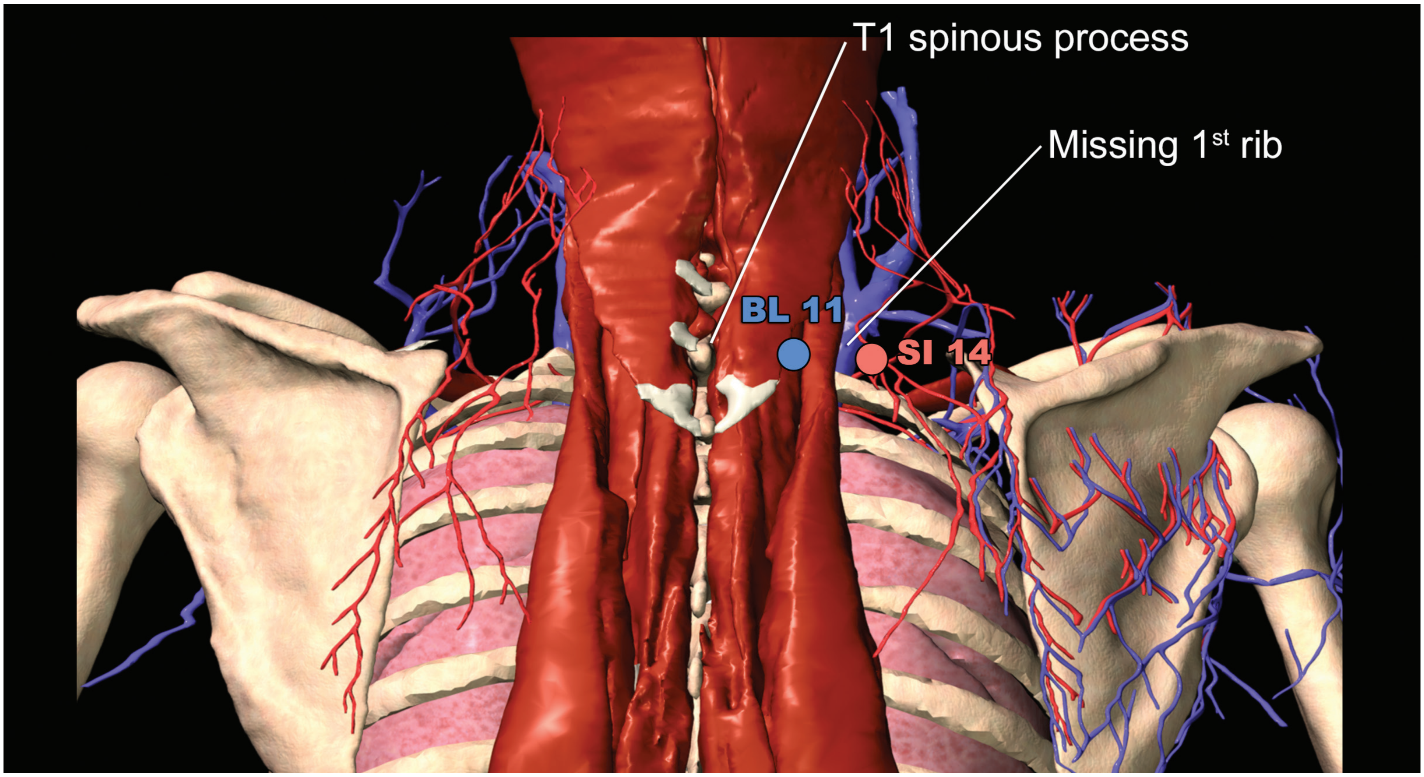

Figure 6-29. The location of SI 14, "Outer Shoulder Transport" puts it 3 cun from the midline, level with BL 11, in line with what will become the outer BL channel.

rhomboids and levator scapulae. On physical examination, the caudomedial border and caudal angle of the scapula become prominent ("winged"); the scapula as a whole moves laterad. Denervation or neuropathy of the dorsal scapular nerve causes the muscles it supplies or thins (levator scapulae and rhomboids) to atrophy; this becomes visible on magnetic resonance imaging. Scapular winging as a result of dorsal scapular neuropathy is much less common than winging from long thoracic nerve injury (supplying the serratus anterior muscle) or spinal accessory neuropathy (innervating the trapezius). Long thoracic nerve palsy produces winging that worsens with arm forward elevation and pushing with outstretched arms. Spinal accessory nerve injury is accentuated by slowly lowering the arms from the arm forward-elevated position. Dorsal scapular nerve injury can be distinguished from C5 root lesion by the absence of abnormal electromyographic findings in other muscles supplied by C5. Rehabilitation includes range of motion, strengthening, and proprioceptive retraining as well as neuromodulation through acupuncture and related techniques. Entrapment of the dorsal scapular nerve due to compression by tension in the middle scalene muscle that it pierces may respond to massage and gentle stretching.

Vessels

- **Transverse cervical artery:** Arises from the thyrocervical trunk, along with the suprascapular artery, to supply the muscles in the posterior cervical triangle, the trapezius, and the medial scapular muscles. After crossing the phrenic nerve and anterior scalene muscle, superior to the clavicle, the transverse cervical artery then courses through the trunks of the brachial plexus.

As it does so, it supplies branches to the vasa nervorum of the plexus. The dorsal scapular artery may branch from the transverse cervical artery, but it occasionally arises from the subclavian artery.

- **Dorsal scapular artery:** This artery arises either from the transverse cervical or subclavian artery, runs deep to the levator scapulae muscle, and supplies the rhomboid muscles. The dorsal scapular artery joins with other arteries (the suprascapular and the subscapular, via the circumflex scapular) around the scapula to form arterial anastomoses. This collateral circulatory route provides another avenue of blood flow in the event of an interruption of blood supply through either the subclavian or axillary arteries. This interruption may result from ligation, in cases of a lacerated axillary or subclavian artery, or from vascular stenosis in the axillary artery secondary to atherosclerosis. In either situation, blood flow in the subscapular artery reverses direction, thereby allowing blood to reach the third part of the axillary artery. (The subscapular artery receives blood from the suprascapular, transverse cervical, and intercostal arteries via several anastomotic junctures.)

Clinical Relevance: The dorsal scapular artery travels intimately with the dorsal scapular nerve. As such, compression or traction injuries of the dorsal scapular nerve would conceivably affect the accompanying artery and vein in a similar fashion.

The transverse cervical artery crosses the phrenic nerve about 3 cm cranial to the clavicle at a right angle; hence the name "Red Cross Syndrome" when ischemic neuropraxia results from arterial compression of the nerve. While it stands anatomically apart from the well-defined prevertebral fascia, surgical, anesthetic, or chiropractic procedures applied to the neck can stretch or transect the nerve. Trauma to the fascia and nerve may result in fibrosis and scarring in the area. Loss of tissue plane separation and adhesion of normally separate anatomical layers invites nerve compression and/or dysfunction.[4] Iatrogenic or traumatic injury to the cervical fascia may similarly impact the transverse cervical artery. Changes to the course and caliber of the artery from anatomical changes, preceding trauma, and/

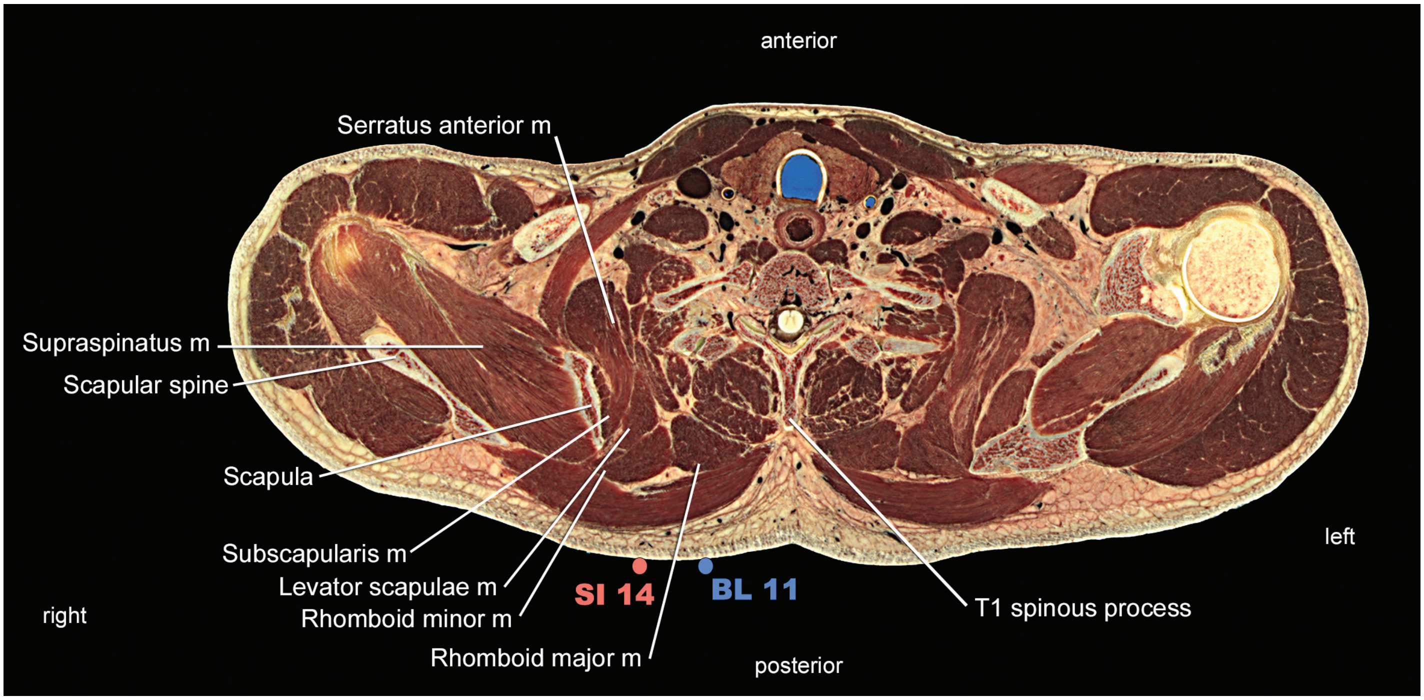

Figure 6-30. The thick, layered musculature beneath SI 14 in this well-developed individual connects the point to its main indication of myofascial trigger point deactivation.

or inflammation can induce further compression of the phrenic nerve that lies deep to it. Phrenic nerve injury in the neck from transverse cervical artery is one source of diaphragm paralysis from peripheral causes.

Indications and Potential Point Combinations

- **Shoulder, neck, upper back pain:** SI 14 included as a local trigger point along with additional regional points exhibiting tenderness to palpation. SI 9, GV 14, SI 6.

Evidence-Based Applications

- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[1]

SI 15

Jian Zhong Shu
"Central Shoulder Transport"

Approximately 2 cun lateral to the posterior midline, level with GV 14 (at the inferior border of the spinous process of C7). The point occurs at about 2/3 the distance from the midline to the medial border of the scapula.

Muscles

- **Trapezius muscle:** Acts on the scapula to elevate, retract, and rotate it.
- **Levator scapulae muscle:** Tilts the glenoid cavity of the scapula inferiorly while rotating and elevating the scapula.
- **Rhomboid minor muscle:** Affixes the scapula against the thoracic wall. Rotates the scapula and retracts it, resulting in causing the glenoid cavity of the scapula to move in an inferior direction.

Clinical Relevance: Figure 6-32 indicates how an acupuncture needle entering SI 15 encounters the trapezius, rhomboid minor, and levator scapulae muscle, depending on needling depth. SI 13, SI 14, and SI 15 reside in a region rich with myofascial trigger points.

Trigger points in the trapezius near SI 15 propel pain toward GV 14. The relationship of these two points appears in Figure 6-31. Levator scapulae trigger points focus pain strongly in the angle between the neck and shoulder. Pain from the levator scapulae muscle extends to the dorsal shoulder and medial scapular border, in rhomboid territory.

Rhomboid pain centralizes over the muscles themselves and emanates diffusely across the scapular region.

Nerves

- **Spinal root of the accessory nerve:** Provides motor output to the trapezius muscle. It also provides motor activity to the SCM, and to the striated muscles of the soft palate, larynx, and pharynx via fibers that join the vagus nerve.
- **C3 and C4 spinal nerves:** Provide pain and proprioceptive function to the trapezius muscle; also supply the levator scapulae muscle.
- **C7 and C8 spinal nerves:** Provide cutaneous sensation to the region.
- **Dorsal scapular nerve (C4,C5):** Innervates the rhomboid minor and major muscles; occasionally innervates the levator scapulae muscle.

Clinical Relevance: Dorsal scapular nerve injury from trauma presents as a sharp pain in the shoulder while lifting heavy objects overhead.[1] Mechanism of injury includes traction or compression of the nerve through extended overhead work. Lifting a heavy box overhead places the dorsal scapular nerve at risk, as do occupational activities (for painters, electricians, dry wallers, etc.) involving raising the arms for long periods of time. Hypertrophy of the middle scalene muscle can lead to dorsal scapular nerve entrapment. Pain arises from strain in compensatory or parascapular muscles or spasm in antagonists of the rhomboids and levator scapulae. On physical examination, the

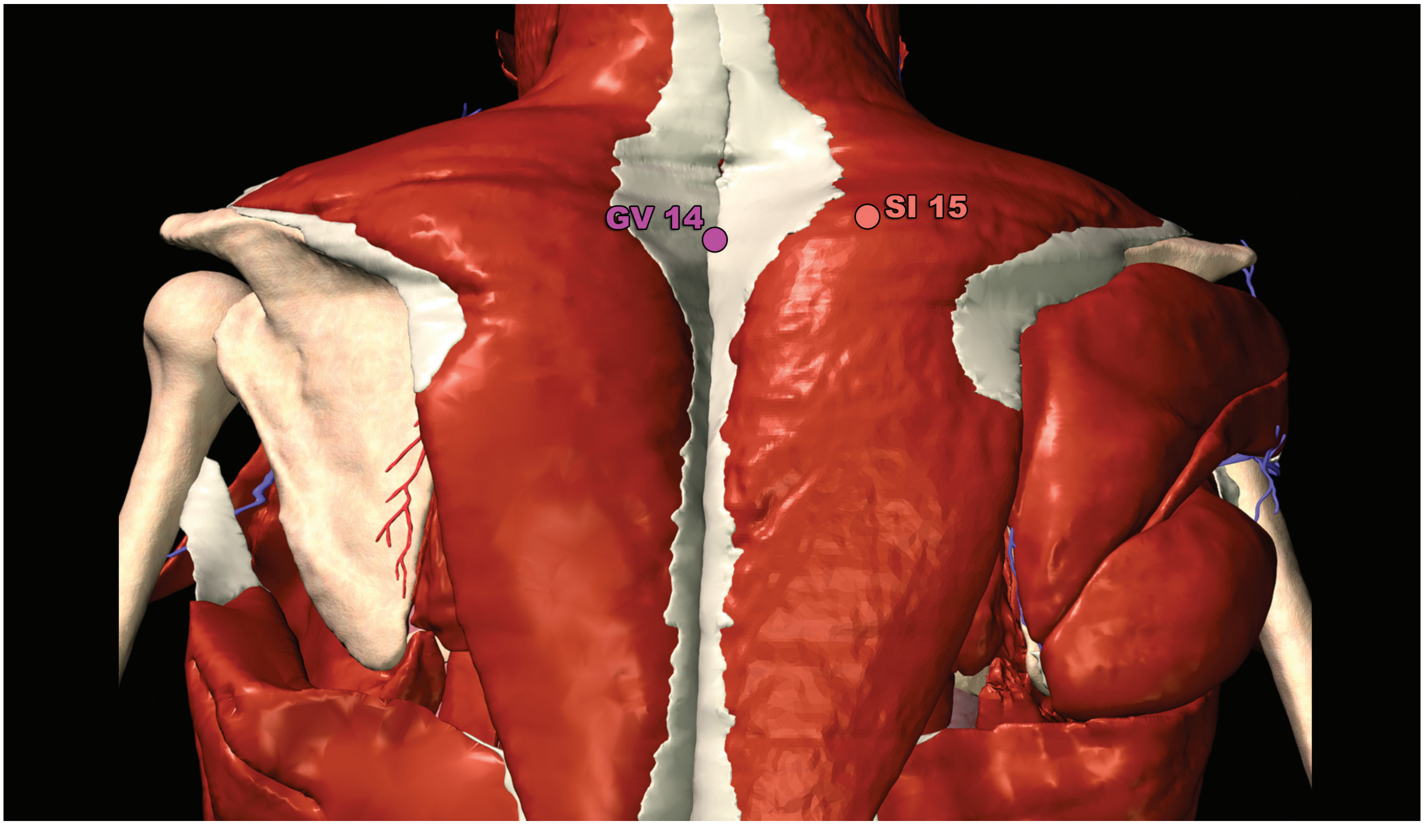

Figure 6-31. Palpating for trigger points in the shoulder and upper back requires careful examination not only of the trapezius muscle, but also underlying layers as becomes apparent in Figure 6-32.

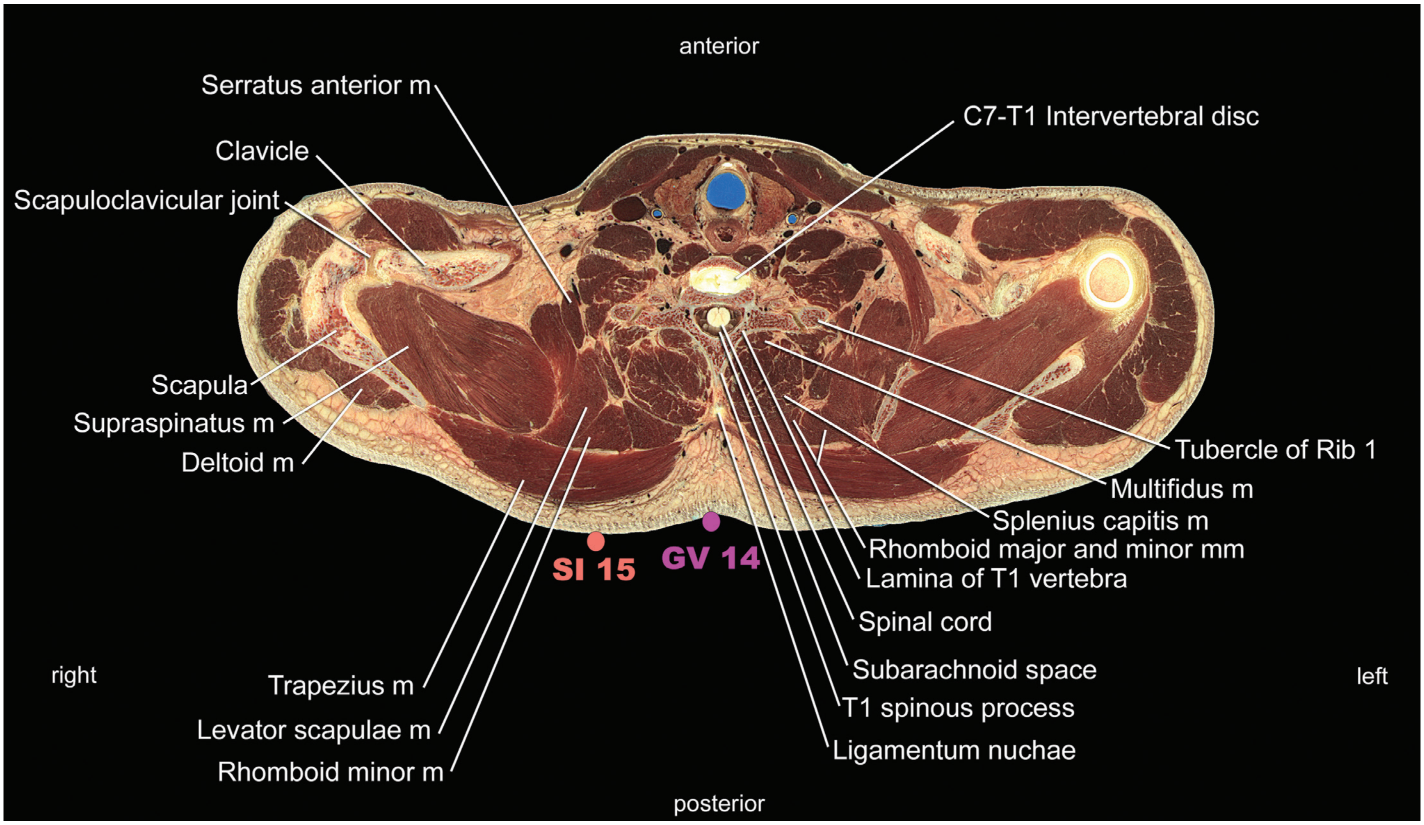

Figure 6-32. Compared to the "Outer Shoulder Shu" (SI 14) in Figure 6-29, the "Central Shoulder Shu" (SI 15) here relates to a more substantive trapezius muscle layer.

caudomedial border and caudal angle of the scapula become prominent ("winged"); the scapula as a whole moves laterad. Denervation or neuropathy of the dorsal scapular nerve causes the muscles it supplies or thins (levator scapulae and rhomboids) to atrophy; this becomes visible on magnetic resonance imaging. Scapular winging as a result of dorsal scapular neuropathy is much less common than winging from long thoracic nerve injury (supplying the serratus anterior muscle) or spinal accessory neuropathy (innervating the trapezius). Long thoracic nerve palsy produces winging that worsens with arm forward elevation and pushing with outstretched arms. Spinal accessory nerve injury is accentuated by slowly lowering the arms from the arm forward-elevated position. Dorsal scapular nerve injury can be distinguished from C5 root lesion by the absence of abnormal electromyographic findings in other muscles supplied by C5. Rehabilitation includes range of motion, strengthening, and proprioceptive retraining as well as neuromodulation through acupuncture and related techniques. Entrapment of the dorsal scapular nerve due to compression by tension in the middle scalene muscle that it pierces may respond to massage and gentle stretching.

Vessels

- **Transverse cervical artery:** Supplies the trapezius and medial scapular muscles, and sends branches to the muscles in the posterior cervical triangle.
- **Dorsal scapular artery:** This artery arises either from the transverse cervical or subclavian artery, runs deep to the levator scapulae muscle, and supplies the rhomboid muscles. The dorsal scapular artery joins with other arteries (the suprascapular and the subscapular, via the circumflex scapular) around the scapula to form arterial anastomoses. This collateral circulatory route provides another avenue of blood flow in the event of an interruption of blood supply through either the subclavian or axillary arteries. This interruption may result from ligation, in cases of a lacerated axillary or subclavian artery, or from vascular stenosis in the axillary artery secondary to atherosclerosis. In either situation, blood flow in the subscapular artery reverses direction, thereby allowing blood to reach the third part of the axillary artery. (The subscapular artery receives blood from the suprascapular, transverse cervical, and intercostal arteries via several anastomotic junctures.)

Clinical Relevance: The dorsal scapular artery travels intimately with the dorsal scapular nerve. As such, compression or traction injuries of the dorsal scapular nerve would conceivably affect the accompanying artery and vein in a similar fashion.

The transverse cervical artery crosses the phrenic nerve about 3 cm cranial to the clavicle at a right angle; hence the name "Red Cross Syndrome" when ischemic neuropraxia results from arterial compression of the nerve. While it stands anatomically apart from the well-defined prevertebral fascia, surgical, anesthetic, or chiropractic procedures applied to the neck can stretch or transect the nerve. Trauma to the fascia and nerve may result in fibrosis and scarring in the area. Loss of tissue plane separation and adhesion of normally separate anatomical layers invites nerve compression and/or dysfunction.[2] Iatrogenic or traumatic injury to the cervical fascia may similarly impact the transverse cervical artery. Changes to the course and caliber of the artery from anatomical changes, preceding trauma, and/or inflammation can induce further compression of the phrenic nerve that lies deep to it. Phrenic nerve injury in the neck from transverse cervical artery is one source of diaphragm paralysis from peripheral causes.

Acupuncture and related techniques alleviate myofascial restriction in the shoulder to allow better blood flow and improve tissue impair. Points to treat include SI 14, SI 15, SI 16, ST 10, ST 11, and LI 18.

Indications and Potential Point Combinations

- **Regional pain or tension:** Palpate the entire region for trigger points, remaining cognizant of the various muscle depths where trigger points may arise; take SI 15 if tender.
- **Respiratory conditions (bronchitis, asthma, cough):** Palpate for trigger points in this region that either impair full thoracic cage expansion or accompany upper thoracic tension due to difficulty breathing or coughing spells. Add LU 7, LI 4, ST 36, BL 13, BL 23.

2. Kaufman MR, Willekes LJ, Elkwood AI, et al. Diaphragm paralysis caused by transverse cervical artery compression of the phrenic nerve: The Red Cross syndrome. *Clinical Neurology and Neurosurgery.* 2012;114:502-505.

SI 16

Tian Chuang "Celestial Window"

On the anterolateral neck, on the dorsal margin of the sternocleidomastoid muscle, level with the laryngeal prominence and LI 18. If the laryngeal prominence is indistinct, first find the depression formed by the lower border of the hyoid bone and the upper border of the thyroid cartilage, along the midline. The laryngeal prominence will lie just below this site.

CAUTION! If one enters the external jugular vein along the dorsal border of the SCM, the tough, investing layer of deep cervical fascia will hold its lumen open. Negative intrathoracic pressure coming from the thorax will cause air to enter the vein, resulting in a venous air embolism, cyanosis, and dyspnea. Thus, either needle superficially or elect to treat with a non-needle neuromodulatory technique.

Muscles

- **Platysma muscle:** Widens the mouth and draws its corners in an inferior direction, as when expressing sadness or fear. Draws the skin covering the neck in a superior direction when one clenches one's teeth.

Clinical Relevance: The platysma muscle presents little resistance to an acupuncture needle here entering SI 16; it would be unusual to treat platysma tension at this site. The cross section in Figure 6-34 illustrates the proximity of the anterior, middle, and posterior scalene muscles to SI 16. Risk of injuring the jugular veins may dissuade medical acupuncturists from inserting needles deeply enough to reach the muscle layer, tempting as it may be to do so. Instead, careful soft tissue therapy provides relief of neuro-compressive muscle tension.

Nerves

- **Transverse cervical nerve (C2 and C3):** Innervate the skin over the anterior triangle, curving around the middle of the posterior border of the SCM, going deep to the platysma muscle.
- **Cervical branch of the facial nerve (CN VII):** Provides motor function to the platysma muscle.
- **Supraclavicular nerves (C3, C4):** Provide sensation to the skin of the neck and part of the shoulder.

Clinical Relevance: SI 16 is located near the site for an interscalene brachial plexus block.[1] The potential for nerve entrapment in this region by tense scalene muscles suggests that carefully performed acupuncture, massage, and laser therapy would aid in the release of myofascial dysfunction as a cause of pain as well as nerve compression.

Vessels

- **External jugular vein and its tributaries:** The external jugular vein drains the side of the face and most of the scalp. It forms as a result of the union of the retromandibular vein and the posterior auricular vein.
- **Ascending cervical artery:** A terminal branch of the thyrocervical trunk, the ascending cervical artery supplies the lateral muscles of the upper neck.

Clinical Relevance: Figure 6-33 exposes the relationship of SI 16 and SI 17 to the external jugular vein. It also shows how the unlabeled SI 18, caudal to the zygomatic arch, lands near the facial vein and SI 19 at the TMJ associates with the superficial vein. Collectively, these correspondences illustrate the vascular basis of acupuncture points and the need for caution when needling sites over large vessels.

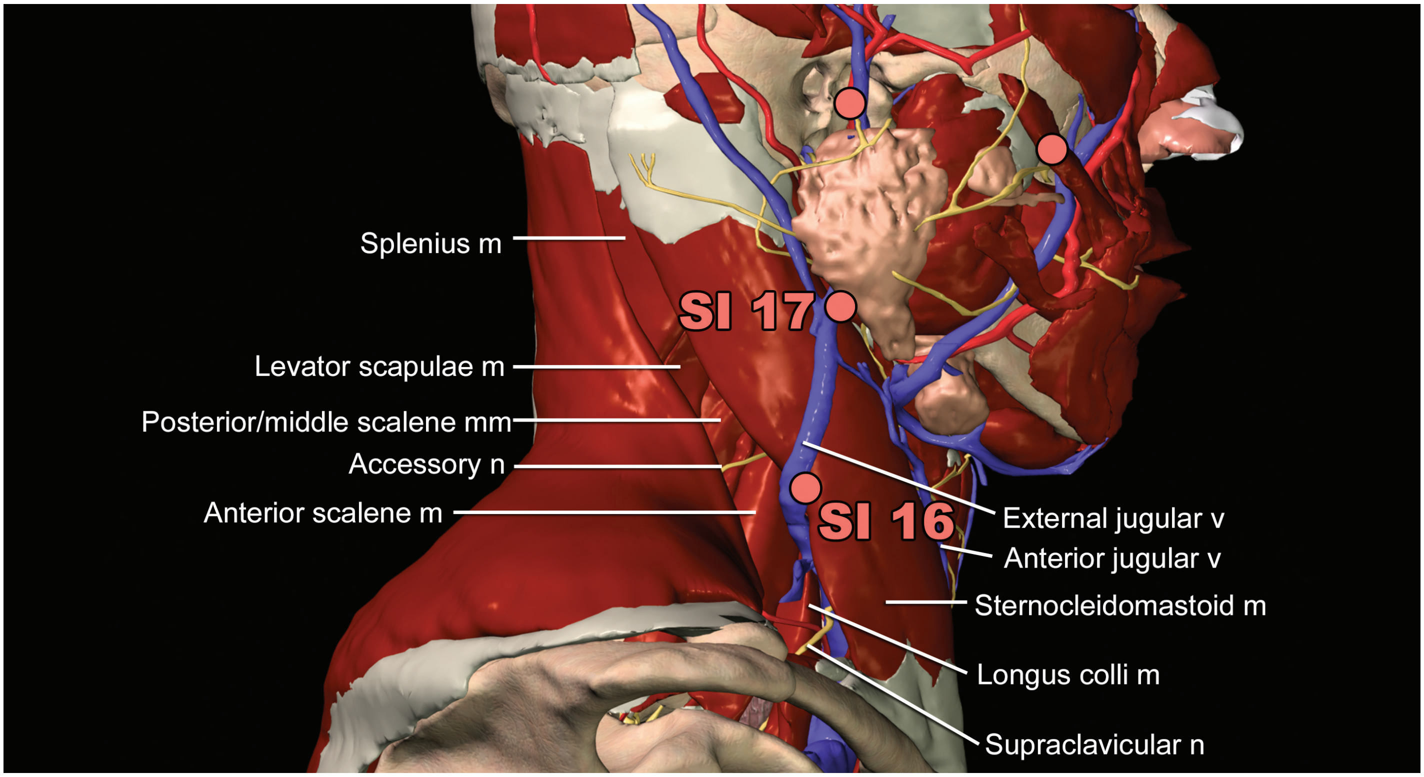

Figure 6-33. Consistent with the SI channel's actions of treating myofascial restriction, SI 16 relates to several muscles that produce neck and head pain, including the anterior, middle, and posterior scalenes, and the sternocleidomastoid muscles.

Figure 6-34. SI 16, the "Celestial Window" describes an access point to the head, metaphorically described as the heavens. As such, it treats problems associated with the head and neck via accessing related nerves and thoracic limb dysfunction by means of its proximity to the brachial plexus.

Indications and Potential Point Combinations

- **Neck pain and restricted motion:** SI 16 if tender to palpation. Determine source of neck pain and additional trigger points. That is, if neck pain stems from upper thoracic myofascial restriction, select additional SI and BL points. If, however, the pain stems from more lateral or anterior sources, a channel-based approach would includes local, proximal, and distal points along that channel, adding neuroanatomically appropriate cervical spinal nerve points supplying those regions and pain sources.
- **Whiplash injury:** SI 16, GB 20, GB 21, GV 20, and relevant trigger points.[2]
- **Torticollis:** SI 16 plus attachment sites of sternocleidomastoid muscle, including GB 12, GB 20, SI 11, CV 22.
- **Tinnitus:** SI 16 with additional points in the neck associated with muscles attaching to the temporal bone, especially the sternocleidomastoid. Add TH points around the ear that express tenderness to palpation.
- **Trismus:** SI 16, SI 17, SI 18, ST 6, ST 7.
- **Throat disorders (pharyngitis, tonsillitis, laryngitis, dysphonia):** SI 16, ST 9, CV 22, CV 23.

SI 17

Tian Rong "Celestial Countenance"

Immediately caudal to the angle of the mandible, in a depression between the angle of the mandible and the ventral border of the sternocleidomastoid muscle. Lands ventral to the transverse process of C2.

Caution needling! This is a highly neurovascular location. See Figure 6-36.

Muscles

- **Posterior belly of the digastricus muscle:** Raises and steadies the hyoid bone when speaking and swallowing. Depresses the mandible.
- **Stylohyoid muscle:** Lengthens the floor of the mouth by elevating and retracting the hyoid bone.

Clinical Relevance: Most individuals report tenderness to palpation at SI 17.[5] This discomfort worsens with temporomandibular joint (TMJ) disorders. However, uncertainty exists about whether the posterior belly of the digastric is indeed palpable. Nonetheless, the myofascial structures found at SI 17 exhibit heightened sensitivity and tension in TMJ dysfunction, teeth clenching, and bruxism. The posterior digastric trigger point has been classically located at or near SI 17. It refers pain strongly to the mastoid and the lateral occipitotemporal region caudad and toward the hyoid bone rostrad.

Trigger points in the digastric group can be compounded by myofascial pathology in the masseter muscle (an antagonist muscle) or the lateral pterygoid that works synergistically to depress the mandible (open the mouth). A "head forward" position develops as a result of contractural shortening of the posterior belly of the digastric muscle with contribution from the stylohyoid and neighboring structures.[6] Habitually carrying the head forward through sustained shortening of the "binding" muscles of the neck, i.e., the stylohyoid, both bellies of the digastric, sternocleidomastoid, and trapezius increases pressure on the upper cervical spine, its joints, and nerves.

Patients with voice disorders often present with myofascial dysfunction of the muscles or supporting structures of the larynx, including a high-held larynx, shortening or contracture of the stylohyoid and sternocleidomastoid muscles, and a weak deep flexor mechanism.

Myofascial restriction at this site, extending to the temporalis and suboccipital regions may perpetuate tinnitus by accentuating pressure or traction on the vestibulocochlear nerve.

Tenderness to palpation at SI 17 suggests further exploration into the source of the problem and treatment of dysfunction with acupuncture or related techniques. Keep in mind the nerves and vessels inhabiting this region.

Nerves

- **Facial nerve (CN VII), cervical branch:** Innervates the stylohyoid muscle and other superficial muscles of the neck, as well as the platysma muscle.
- **Great auricular nerve (C2, C3):** Innervates the parotid sheath and skin overlying the parotid gland; also supplies the posterior part of the auricle and the skin between the mandible and mastoid process.
- **Hypoglossal nerve (CN XII):** Supplies all of the extrinsic and intrinsic lingual muscles except for the palatoglossus. Carries

Figure 6-35. SI 17, Celestial Countenance, refers to the migration of the SI line onto the face. Each of the points located here (SI 16 – SI 19) may exhibit tenderness to palpation in TMJ dysfunction. Myofascial restriction in SI 9 – SI 15 contributes to the syndrome.

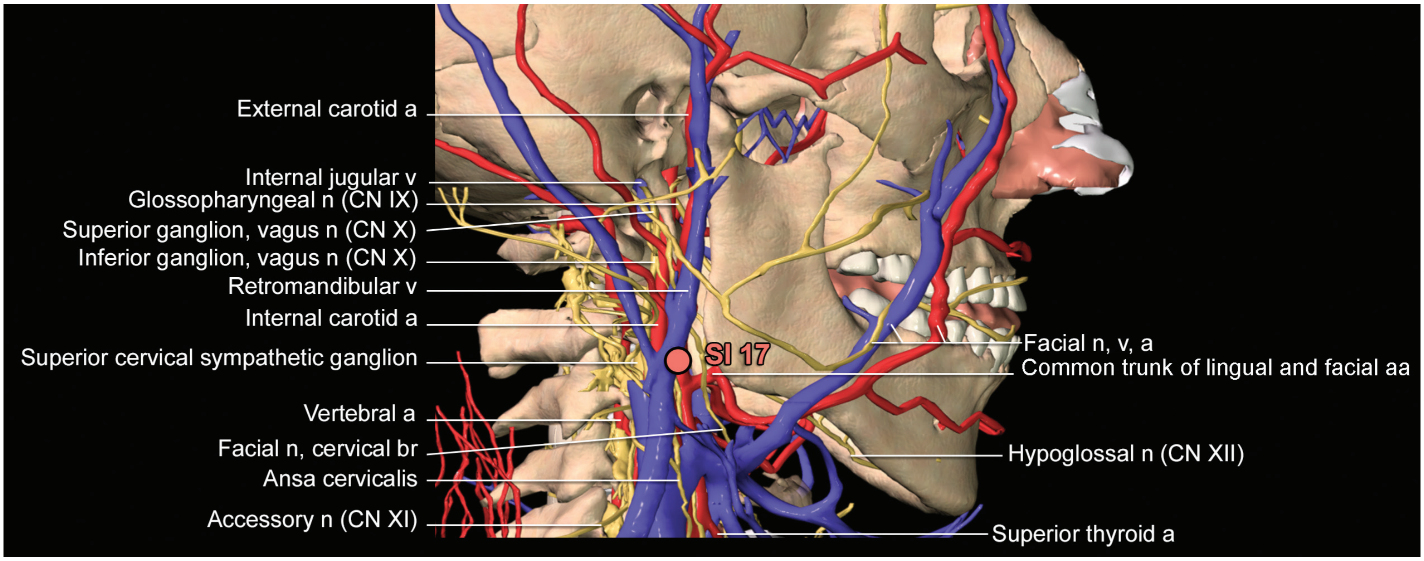

Figure 6-36. SI 17 associates with several significant neurovascular routes, justifying caution when introducing a needle into this area.

motor fibers from the C1 and C2 spinal nerves whose destination is the hyoid muscles (i.e., the thyrohoid and geniohyoid muscles). Carries proprioceptive fibers to the aforementioned muscles and, via a meningeal branch, the dura in the posterior cranial fossa.

- **Superior cervical ganglion of the sympathetic trunk (T1-T5):** Provides postsynaptic cephalic arterial rami, forming the internal carotid sympathetic plexus, which travel along the internal carotid artery and into the cranium. The superior cervical sympathetic ganglion also sends rami to the external carotid artery and branches to the C1-C4 spinal nerves. Postsynaptic fibers emerge from the superior cervical ganglion to their destination in the cardiac plexus of nerves via a cardiopulmonary splanchnic nerve.
- **Vagus nerve (CN X):** Provides taste sensation in the regions of the root of the tongue and epiglottis; proprioceptive and motor function to the muscles of the soft palate, pharynx, intrinsic laryngeal muscles (which afford phonation), and the palatoglossus muscles; sensation to the inferior pharynx, larynx, and thoracoabdominal viscera, and parasympathetic function to the thoracoabdominal viscera. The general sensory aspects of CN X relate predominantly to the superior ganglion of CN X, while the inferior ganglion relates largely to the visceral sensory functions of CN X. The nerve in this region connects to CN IX, CN XI, and the superior cervical sympathetic ganglion. Near the site of its exit from the jugular foramen, the vagal nerve receives a cranial root from CN XI, a meningeal branch from the dura mater, and the auricular branch of the vagus nerve. As the vagus nerve continues its descent, it enters the carotid sheath on its way the root of the neck. Branches of the vagus in this region include the pharyngeal nerves, superior laryngeal nerve, right recurrent laryngeal nerve, and the cardiac nerves. (The left recurrent laryngeal nerve branches from the vagus as it passes through the superior thoracic aperture into the thorax.)

Clinical Relevance: The rich supply of nerves and vessels at SI 17 translates into potentially powerful autonomic effects by stimulating the structures at this site. Both cranial and autonomic nerves traverse the region, as shown in Figure 6-36. Due to the revision in autonomic firing patterns that may result from needling this site, treat cautiously to avoid traumatizing delicate structures or inducing vasovagal syncope.

Vessels

- **External jugular vein and its tributaries:** The external jugular vein drains the side of the face and most of the scalp. It forms as a result of the union of the retromandibular vein and the posterior auricular vein.
- **Interior jugular vein (IJV):** The largest vein in the neck, the IJV drains blood from the deep cervical muscles and cervical viscera, the face, and the brain. It begins in the posterior cranial fossa at the jugular foramen, and comprises a direct continuation of the sigmoid sinus of the brain. It courses through the neck within the carotid sheath, along with the internal/common carotid artery and vagus nerve. (The cervical sympathetic trunk lies posterior to the carotid sheath, embedded within the prevertebral fascia.)
- **External carotid artery (ECA):** Supplies extracranial structures; the middle meningeal artery is a branch of the ECA that supplies intracranial structures. Terminates as the maxillary artery and superficial temporal artery. Other branches include the ascending pharyngeal, superior thyroid, lingual, facial, occipital, and posterior auricular arteries.

Clinical Relevance: Needling SI 17 may cause profound hemodynamic changes due to the autonomic fibers in the vicinity. Palpate the region carefully before inserting an acupuncture needle to target myofascial structures and not pulsating structures.

Indications and Potential Point Combinations

Evidence-Based Applications

- Stimulation of SI 17 may benefit **migraine** by inhibiting neurogenic inflammation of blood vessels in the dura mater on the affected side.[1,2]
- Needling the local points ST 3, ST 5, ST 6, ST 7, SI 17, LI 18, TH 17, and GV 20, plus the distal points HT 7, PC 6, LI 3, LI 4, LI 11, TH 5, ST 36, SP 6, GB 41, LR 3, KI 3, and KI 5, provided significant long-term relief of **xerostomia** due to either primary or secondary Sjögren's syndrome, irradiation, or other causes.[3]
- A case series involving acupuncture at LI 4, TH 5, LR 3, ST 36, ST 7, ST 6, and SI 17, splint therapy, and point injection therapy suggested that this combination was effective for managing **temporomandibular disorders.**[4]

SI 18

Quan Liao "Cheek Bone Hole"

In a depression below the zygoma, directly inferior to the lateral canthus of the eye. See Figure 6-39 to examine the bony relationships.

Muscles

- **Zygomaticus major muscle:** Draws the angle of the mouth in a superolateral direction, as when one smiles.
- **Masseter muscle:** Closes the jaw; retrudes it with deep fibers. Myofascial dysfunction of the masseter muscle can lead to temporomandibular joint dysfunction, restricted jaw opening, and unilateral (and occasionally bilateral) tinnitus.[1]

Clinical Relevance: Myofascial restriction in the masseter and lateral pterygoid muscles may respond to local treatment at SI 18. Select SI 18 for facial nerve injury affecting the zygomaticus major muscle. Trigger points in the lateral pterygoid refer pain to SI 18 and SI 19.

Nerves

- **Zygomatic branch of facial nerve (CN VII):** Innervates the muscles inferior part of the orbicularis oculi and other facial muscles inferior to the orbit.
- **Masseteric nerve (CN V_3):** Provides motor output to the masseter muscle.

Clinical Relevance: The proximity of SI 18 to the zygomatic branch of the facial nerve emphasizes this point's relevance in cases of peripheral facial nerve paralysis.[6]

Vessels

- **Transverse facial artery:** Arises from the superficial temporal artery, within the parotid gland. Supplies the parotid gland, the parotid duct, and the skin and muscles of the face.
- **Deep facial vein:** Originates from the pterygoid venous plexus, and drains into the facial vein. It receives blood from the regions supplied by the maxillary artery, including the infratemporal fossa.

Clinical Relevance: Restoration of function in the muscles of facial expression is supported by improvement of local circulation. Moreover, vascular compromise worsens pain and dysfunction in trigger point pathology.

Indications and Potential Point Combinations

- **Facial nerve injury affecting the zygomatic branch:** SI 18; add TH 17 to treat facial nerve trunk.
- **Facial nerve injury affecting multiple branches:** TH 17, SI 18, ST 4, LI 20, Taiyang, GB 14, and Yintang.
- **Maxillary sinus pain:** SI 18, ST 2, ST 3, ST 44, LI 4
- **Tinnitus:** For tinnitus generated by trigger points, find tender areas in the temporalis, masseter, trapezius, sternocleidomastoid, and occipitofrontalis muscles. In addition to SI 18, and myofascial trigger points, consider tender TH and GB points encircling the ear, as well as SI 19.
- **Temporomandibular dysfunction:** Identify myofascial contribution to TMJ dysfunction. In addition to SI 18, consider SI 19, temporal trigger points, and SI, BL, or GB points in the neck and shoulder regions that may refer pain to the TMJ or contribute to myofascial restriction.

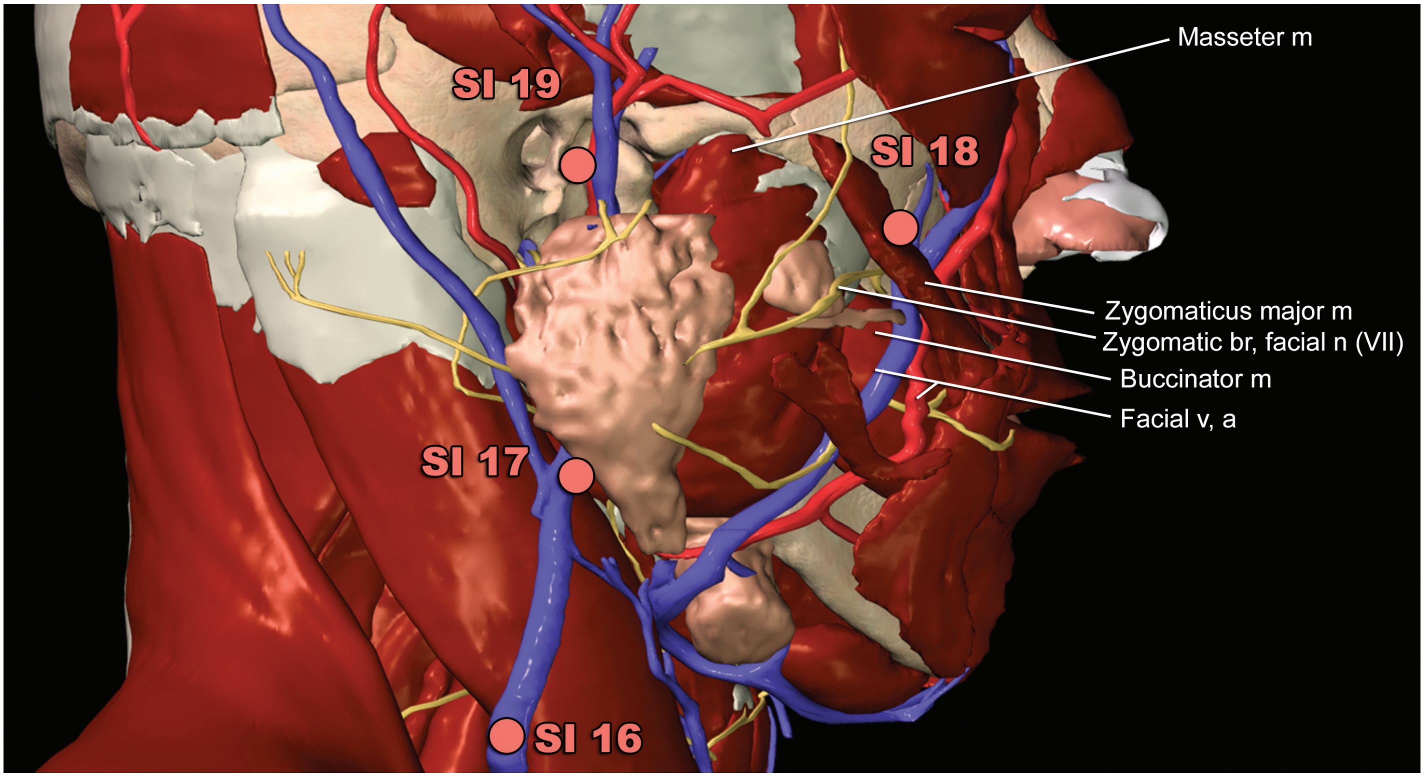

Figure 6-38. SI 18 resides squarely over the muscle belly of the zygomaticus major muscle and on the rim of the masseter.

- Used in acupuncture analgesia for brain surgery and tooth extraction.[2]

Evidence-Based Applications

- Three out of three RCTs supported the effectiveness of acupuncture for the treatment of **temporomandibular disorders,** prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[3]
- A case series reported that electroacupuncture at GB 14, SI 18, ST 7, GB 20, and LI 4 was effective treatment for **peripheral facial paralysis.**[4]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, SI 18, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, and GB 44.[5]
- **TMJ dysfunction:** ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4, dry needled with deqi achieved, left in situ for 30 minutes.[7]
- **Peripheral facial nerve paralysis:** ST 4, ST 7, ST 6, CV 24, LI 20, SI 18, TH 17, GB 14, ST 2, GB 20, GV 26, Yuyao (in the middle of the eyebrow), and LI 4.[8]

SI 19

Ting Gong "Palace of Hearing"

In a depression located between the middle of the tragus and the condylar process of the mandible. Easiest to find with the mouth open.

Connective Tissues

- **Fibrous capsule of the temporomandibular joint (TMJ):** This capsule attaches to the temporal bone's articular area and around the neck of the mandible.
- **Lateral (TMJ) ligament:** This thickening of the articular capsule is an intrinsic ligament which strengthens the TMJ from the lateral direction; works in conjunction with the postglenoid tubercle to prevent posterior dislocation of the TMJ.
- **Articular disc:** The articular disc divides the TMJ cavity into two compartments, an inferior and superior one.

Clinical Relevance: Note the proximity of SI 19 to the TMJ in Figure 6-38. Degeneration of the disk, ligament, capsule, or joint components accentuates dysfunction and pain.[3] TMJ disorders are multifactorial in origin, however, with contribution from myofascial structures of the neck and shoulders. As such, it is customary to add SI points on the neck and shoulders, as well as relevant BL and GB locations.

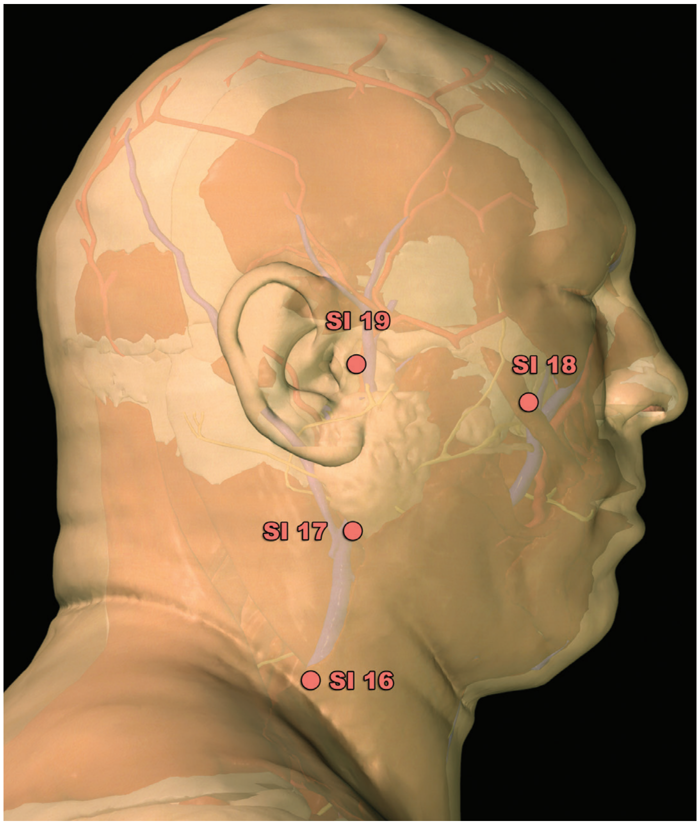

Figure 6-41. The name "Auditory Palace" for SI 19 refers to its proximity to the ear. In addition, alleviating compressive forces on the TMJ contributes to the resolution of tinnitus connected to myofascial dysfunction of the head and neck.

Nerves

- **Auriculotemporal nerve from mandibular nerve (CN V_3):** Carries parasympathetic fibers to the parotid gland and supplies sensation to the gland. Also supplies sensation to the skin in the following regions: tragus, anterosuperior helix and auricle, roof of the external acoustic meatus, upper tympanic membrane, and the regions anterior to the ear and in the posterior temporal region.
- **Sympathetic fibers from the cervical ganglia:** These fibers travel to the parotid gland via the external carotid nerve plexus accompanying the external carotid artery.

Clinical Relevance: Neuromodulation of nerves supplying the TMJ, local musculature, and nearby vessels provides analgesia and alleviates myofascial dysfunction for this craniomandibular disorder.

Vessels

- **Superficial temporal artery and anterior auricular branches:** The superficial temporal artery is a terminal branch of the external carotid artery, and travels anterior to the ear toward the temporal region, ending in the scalp. It supplies the skin of the frontal and temporal regions as well as the muscles of the face.
- **Superficial temporal vein:** This vein begins on the scalp as a widespread plexus, and also covers the zygomatic arch, draining the scalp, superficial parts of the temporalis muscle, and the external ear. It joins with the maxillary vein posterior to the mandible, forming the retromandibular vein (see below).
- **Retromandibular vein:** The retromandibular vein forms as a result of the union of the maxillary and superficial temporal veins, anterior to the ear. It later joins with the posterior auricular vein to create the external jugular vein. The retromandibular vein drains the parotid gland and masseter muscle.

Clinical Relevance: Direct the acupuncture needle away from vessels and toward, but not into, the joint.

Indications and Potential Point Combinations

- **Tinnitus:** SI 19, trigger points in muscles connecting to the temporal bone, tender TH points encircling the ear, TH 5. GB 20, BL 10, GV 20. Massage to provide gentle traction to the suboccipital region. Deactivate trigger points in the temporalis muscle.
- **Temporomandibular joint (TMJ) dysfunction:** SI 19, SI 18 (sometimes connected to SI 19 with electrical stimulation), and local trigger points in the temporal, cervical, and upper thoracic region.
- **Dental pain:** SI 19, LI 4, LU 7.

Evidence-Based Applications

Electroacupuncture of SI 19 and LI 11 was more effective in **lowering blood pressure** than were other points paired with LI 11.[1] This effect appeared to be related to central opioid and/or noradrenergic mechanisms.[2]

Channel 7:: The Bladder (BL)

The Bladder channel starts just above the inner canthus of the eye. It ascends the Forehead and descends along the erector spinae in two parallel lines to the sacrum. After crisscrossing the caudal thigh, the BL channel reunites in the popliteal fossa, terminating at BL 67 on the little toe.

Myofascial referred-pain patterns link the BL line from head to toe. Dorsher enumerates the connecting muscles as follows: Occipitalis, splenius capitis, semispinalis capitis, multifidi, rhomboids, trapezius, serratus posterior inferior, longissimus thoracis, iliocostalis lumborum, piriformis, hamstring group, popliteus, gastrocnemius, soleus, tibialis posterior, abductor digiti minimi.[1] The BL channel also closely follows Myers' Superficial Back Line anatomy train.[2]

From head to toe, the BL line follows spinal nerves, that is, as long as one includes the spinal nucleus and tract of the trigeminal nerve (V). On the rostral cranium, BL 1-BL 7 associate with the trigeminal nerve. Trigeminal afferents from the face and mouth course to the spinal nucleus of V. The spinal tract and nucleus of V also associate with the facial, glossopharyngeal, and vagus nerves. This allows for crosstalk between the cranial nerves, explaining in part how stimulating points on the face and head lead to autonomic changes in organs and tissues supplied by CN VII, CN IX, and CN X, respectively. BL 2 through BL 10 play prominent roles in headache treatments, especially when palpatory tenderness or referred pain patterns argue for their participation. Whether the headache originates from intracranial or extracranial sites, the extensive communication between trigeminal, vagal, upper cervical, and autonomic nerve pathways allows for stimulation of BL 2 through BL 10 to modulate nervous system activity on various levels.

BL 4
BL 9

Cranial and cervical myofascial dysfunction often leads to headaches at the vertex and back of the head. Trigger points in the sternocleidomastoid muscle (sternal head) and splenius capitis can cause vertex pain. Pain at the back of the head includes patterns referred from trigger points in the trapezius, sternocleidomastoid (sternal or clavicular heads), semispinalis capitis and cervicis, suboccipital, occipitalis, digastricus, and temporalis muscles.

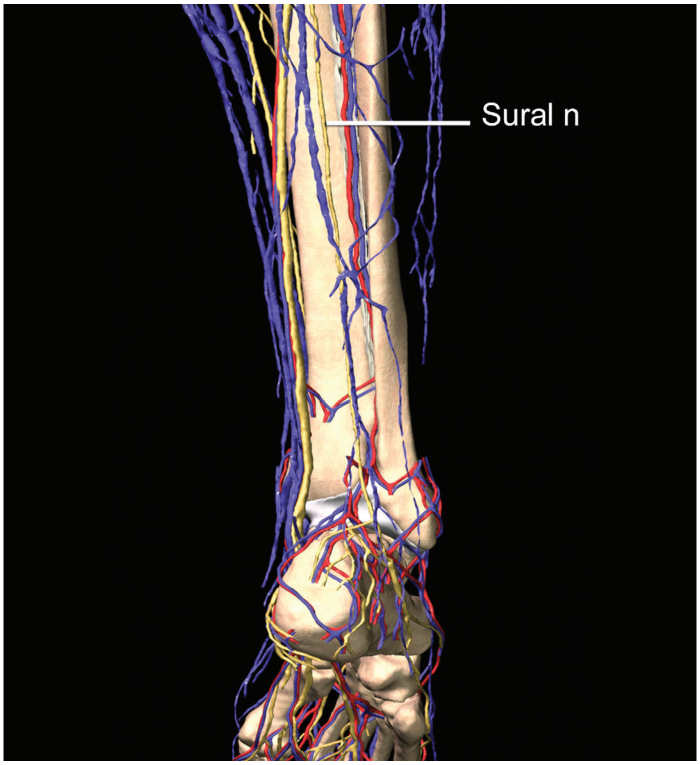
More deeply, BL points overlap the sciatic nerve, separating at BL 38 into the tibial nerve at BL 40 and the common fibular (peroneal) nerve at BL 39.



The sural nerve, comprised of tibial and fibular (peroneal) contributions, follows the BL channel as it courses from the crus to the foot. Note how the nerve issues branches to the caudal heel (BL 61) and calcaneus (BL 62) before it continues on its way to the little toe (BL 63 – BL 67).

BL 1

Jing Ming "Bright Eyes"

With the patient's eye closed, the point is found in the small fossa 0.1 cun dorsolateral to the medial canthus.

CAUTION: Avoid penetrating the globe and area vessels. Some suggest gently pressing the globe in a lateral direction, then inserting the needle near the superior aspect of the lacrimal sac and directing the needle medially. No needle lifting and thrusting or twirling should be done.

Note: The risk of penetrating or injuring the globe and impacting vision exists when needling any periocular acupuncture points, especially BL 1 and ST 1. Ophthalmologists have written, regarding an instance of eye injury and vision loss following periocular acupuncture, "We believe that the use of acupuncture in and around the eye is an extremely risky procedure, with no solid evidence of its benefit, and advise against its use."[3] This emphasizes weighing risks versus benefits of needling sites where injury may occur.

Muscles

- **Orbicularis oculi muscle, palpebral and lacrimal parts:** The orbicularis oculi acts as a sphincter muscle for the eyelids. The palpebral portion shuts the lids, as when one blinks. The lacrimal portion resides deep to the palpebral part, promoting lacrimal fluid flow by compressing the lids onto the globe, and dilating the lacrimal sac by tugging on the lacrimal fascia. The neuroanatomic proximity of the orbicularis oculi and orbicularis oris motoneuronal pool in the brainstem subnuclei may explain why eyelids close during deglutition. That is, the motoneurons connect at the deglutitional center in the brainstem, such as in the nucleus tractus solitarius after intraoral trigeminal afferents activate swallowing centers and, simultaneously, efferent fibers to the orbicularis oculi muscle.[4]

Clinical Relevance: Blepharoplasty (eyelid surgery) poses the risk of causing dry eye and chemosis (edema of the conjunctiva). Facial nerve injury (temporal and zygomatic branches) causes inability to close the eyelid. Horner's syndrome causes ptosis (eyelid drooping), miosis and anhidrosis of the ipsilateral face, and conjunctival redness. Each of these pathologies affecting the eyelid has different etiologies and nerve pathways affected. As such, acupuncture approaches would differ for distal and homeostatic points, though local stimulation sites might overlap.

View the location of BL 1 on the orbicularis oculi muscle in Figure 7-3. The main indication for BL 1 is epiphora, in light of its association with the lacrimal part of the orbicularis oculi muscle that assists in the drainage of tears. Treatment of other eye conditions can more safely be addressed with less risky points.

Nerves

- **Infratrochlear nerve (terminal branch of nasociliary nerve, CN V_1):** Innervates the skin on the medial upper lid, the side and bridge of the nose, and the lacrimal sac.
- **Ophthalmic nerve (from which all other branches of CN V_1 arise):** The smallest of the three divisions of the trigeminal nerve (CN V), the ophthalmic nerve carries only sensory information. After emerging through the superior orbital fissure and entering the orbit, the ophthalmic nerve branches to form the nasociliary nerve, the frontal nerve, and the lacrimal nerve. Further divisions produce five cutaneous branches: the external nasal, infratrochlear, supratrochlear, supraorbital, and lacrimal nerves. The ophthalmic nerve supplies innervation to the dura of the posterior cranial fossa via the tentorial nerve.
- **Temporal branch of the facial nerve, CN VII:** Innervates the orbicularis oculi, upper lid portion.

Clinical Relevance: BL 1's main influence pertains to epiphora through its actions on the lacrimal part of the orbicularis oculi muscle, supplied by the facial nerve. It may also reduce pain for conjunctival disorders afflicting the medial canthus.

Vessels

- **Angular vein:** Drains the upper and lower lids and the conjunctiva; it may receive drainage from the cavernous sinus.
- **Anastomoses of the angular artery and vein with the ophthalmic artery and vein, respectively:** Supply and drain the orbit, including the retina.
- **Dorsal nasal artery:** Supplies the dorsal surface of nose.

Clinical Relevance: Stimulation of BL 1 alters circulation in nearby tissues. Deep within the orbit, the anterior ethmoidal artery branches off of the ophthalmic artery in the medial orbit. An ill-advised deeply inserted needle at BL 1 would traverse the skin, subcutaneous tissue, the medial palpebral ligament, the medial rectus, and the orbital adipose body.[5] If this needle angled dorsad, it could damage the anterior ethmoidal vessels. While a Chinese study recommends that needling depth at BL 1 not exceed 30.36 mm, this far exceeds acceptable depth for safety. Review the anatomy near the globe visible in the cross section of Figure 7-4.

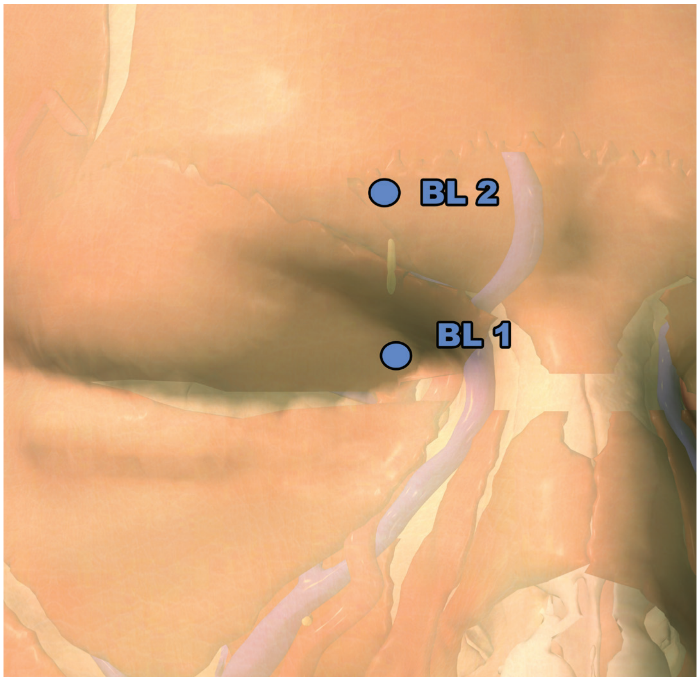


Figure 7-1. BL 1, "Bright Eyes", supposedly improves the health of the eye and clarifies vision. However, the possibility of injuring the globe with deep insertion poses safety hazards. As such, BL 2 frequently stands in for BL 1.

Figure 7-2. The dense and varied nerve supply of acupuncture points surrounding the eye help explain the neurophysiologic effects of acupuncture for eye conditions. Specifically, the indications for BL 1 of epiphora, eye pain, and blepharospasm relate to the local nerve supply from the ophthalmic division of the trigeminal nerve and the temporal branch of the facial nerve.

Figure 7-4. BL 1 must be needled cautiously in order to avoid injuring the globe. This cross section illustrates how an acupuncture needle could reach the medial rectus muscle but it fails to show the vessels and nerves at risk, other than the optic nerve. The cross section at the level of BL 1 also displays the neuroanatomy of the visual system from the globe to the optic nerve, optic chiasm, optic tract, superior colliculus, optic radiation, and occipital cortex.

Indications and Potential Point Combinations

- **Eye problems: watery eyes, epiphora, visual disturbances, conjunctivitis, iritis, retinitis, eye pain, blepharospasm:** BL 1 or BL 2, GV 24.5 (Yintang), GB 14, GB 1 or TH 23, GV 20, ST 36.

Evidence-Based Applications

- Two series of cases indicated that BL 1 may be of benefit in cases of **epiphora.**[1,2]
- **Peripheral facial nerve** injury with inability to close the eyelid: BL 1, GB 14, and ST 2.[6]

BL 2

Zan Zhu "Gathered Bamboo"

[The name for BL 2, "Bamboo Gathering", denotes the likeness of the eyebrows to the bamboo leaves apposed on a stem.]

In the shallow depression at the medial end of the eyebrow, in the supraorbital notch or foramen, superior to BL 1. Often tender to palpation.

Muscles

- **Frontal belly of epicranius (occipitofrontalis) muscle:** Wrinkles the forehead, elevates the eyebrow.
- **Corrugator supercilii muscle:** A muscle of facial expression that demonstrates concern. The corrugator supercilii muscles move the eyebrows toward each other and metaphorically "gather bamboo"; hence the name.

Clinical Relevance: Migraines may arise from tension in the forehead muscles such as the corrugator supercilii, deep to the eyebrow. Although some plastic surgeons have noted that elimination of this muscle leads to significant improvement in migraine-associated head pain,[4] nonsurgical trigger point deactivation through acupuncture and related techniques should be tried first. Trigger points in the attachment of the frontalis muscle near BL 2 also produce forehead pain.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V_1):** The supraorbital nerve is the largest of five branches of the ophthalmic division of the trigeminal nerve to reach the skin of the face. Innervates the mucous membrane of the frontal sinus and upper eyelid (palpebral conjunctiva); supplies skin of forehead to the hairline. The supraorbital nerve divides into deep and superficial branches. The deep branch courses between the galea aponeurotica and the periosteum. The superficial branch passes through the rostral frontalis muscle and courses caudally over the muscle to supply the scalp. Branches of both the superficial and deep components of the supraorbital nerve head toward the vertex and GV 20, helping explain that point's name of "Bai Hui" or Hundred Convergences.
- **Supratrochlear nerve (from frontal nerve, CN V_1):** Innervates the mucosal lining of the frontal sinus and the skin in the middle of the forehead. The supratrochlear nerve supplies the skin near the midline (GV channel) of the rostral scalp while the supraorbital nerve's medial and lateral branches follow the BL line.
- **Temporal branch of the facial nerve, CN VII:** Innervates the corrugator supercilii muscle and the frontal belly of the occipitofrontalis muscle.

Clinical Relevance: BL 2 coincides with the site of supraorbital nerve block.[5] Pain in the eye or head associated with the supraorbital nerve or, more broadly, the ophthalmic division of the trigeminal nerve, often responds to neuromodulation at this and other relevant sites. This includes not only pain in the head but also the sinuses.

Vessels

- **Supratrochlear artery:** Supplies the muscles and skin of the scalp.
- **Supratrochlear vein:** Drains the anterior part of scalp and forehead.

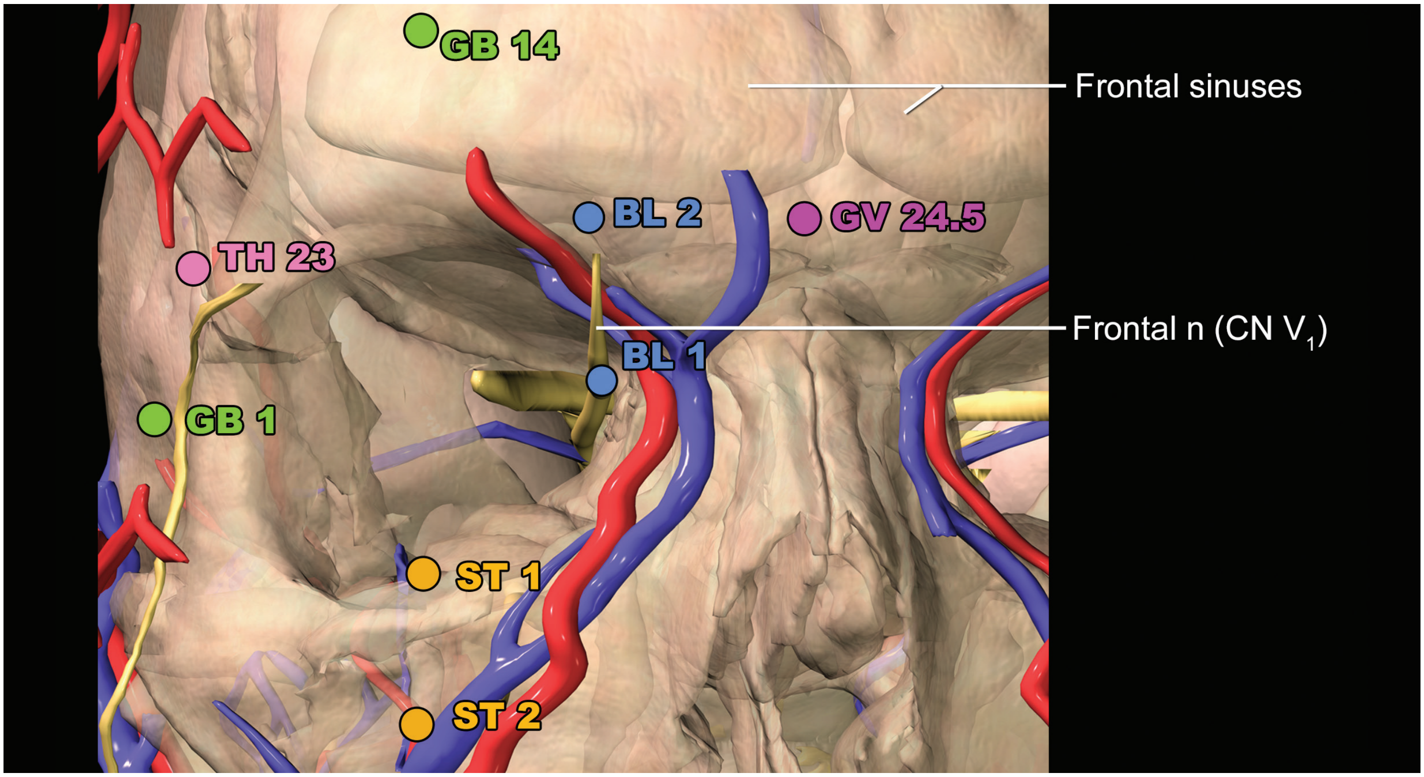

Figure 7-5. In addition to its effects on the eyes, BL 2 affects frontal sinus pain via the supratrochlear nerve, a trigeminal nerve branch that supplies the mucosal lining of the sinus. The semitransparent skull shown here depicts the relationship of BL 2 to the sinuses.

Figure 7-6. The relationship between the frontal sinus (denoted in blue) and BL 2 can be seen in this cross section. Trigeminal sensory fibers supply both, which helps justify the indication of frontal sinusitis for BL 2. In addition, the dura mater can be seen between the brain and calvarium. The rostral dura receives trigeminal sensory supply, suggesting an avenue for trigeminal neuromodulation through points on the head that influence the ophthalmic division.

- **Supraorbital artery:** Supplies the muscles and skin of the forehead and scalp. The supraorbital artery often issues a branch to the diploë at the foramen. See Figure 7-11 to view a supraorbital vessel in cross section.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.

Clinical Relevance: The supratrochlear, infraorbital, and branches of the facial arteries form an anastomotic relationship within the paranasal and medial canthal region.[6] Thus, improving circulation through stimulation of BL 2 can benefit blood flow in other portions of the orbit. See Figure 7-5 to note the vascular continuity exhibited at the medial canthus. Also note in Figure 7-5 the oblique branch of the supraorbital artery coursing toward GB 14. A study evaluating the vascular anatomy of the forehead found this branch frequently anastomoses with either the transverse frontal artery or the frontal branch of the superficial temporal artery.[7] Figure 7-5 shows this frontal branch above TH 23 reaching toward BL 2, reinforcing that circulatory stimulation at one site may have more widespread effects than previously considered.

Indications and Potential Point Combinations

- **Frontal sinus congestion and/or headache:** BL 2, BL 10, GV 24.5 (Yintang), LI 4, ST 36.
- **Dry eye:** BL 2, TH 23, GB 14, GV 20, GB 20, ST 36, LR 3.
- **Migraine:** BL 2, LI 4, LR 3, BL 10, GV 20.

Evidence-Based Applications

- Acupuncture at ST 2, ST 8, ST 36, GB 1, GB 14, BL 2, and LI 4 provided subjective beneficial effects in patients with **keratoconjunctivitis sicca (KCS, or dry eye).**[1]
- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **KCS**.[2]
- Case report indicated that **hiccoughs** were successfully treated with digital pressure on BL 2, followed by moxibustion.[3]
- Dry eye, with BL 2, GB 14, TH 23, ST 1, GB 20, LI 4, LI 11, GV 23, Sishencong (EX-HN-1); tear film break-up time significantly improved after acupuncture, as did **ocular surface disease** index.[8]

BL 3

Mei Chong "Eyebrow's Pouring" (or "Eyebrow Ascension")

Directly above BL 2, .5 cun caudal to the rostral hairline, level with GV 24 and BL 4.

If unsure of the location of the anterior hairline (i.e., it is either indistinct or absent), measure the distance between the glabella (at point GV 24.5, or Yintang) and the caudal hairline, which equals 15 cun. The rostral hairline occurs one-fifth (=3 cun) the distance from the glabella to the caudal hairline. If the caudal hairline is indistinct as well, that line can be taken 1 cun caudal to GV 16, or Fengfu, immediately below the external occipital protuberance.

Muscles

- **Frontal belly of epicranius (occipitofrontalis) muscle:** Wrinkles the forehead and elevates the eyebrow.

Clinical Relevance: The occipitofrontalis muscle comprises two physiologically and anatomically distinct muscles.[2] The rostral limit of the galea aponeurotica in the vicinity of BL 3 and BL 4 creates a unique layering system that raises the possibility of nerve entrapment. That is, the superficial fascia over the occipital belly turns into the temporoparietal fascia that attaches to the superior, or upper, border of the frontalis muscle. This superficial musculoaponeurotic complex lifts the eyebrow and pulls the scalp rostrad. In contrast, the occipital belly of the occipitofrontalis muscle joins with the galea aponeurotica and inserts on the deeper aspect, or underside, of the frontalis muscle, forming the deep musculoaponeurotic system. The occipital muscle attachment gives this layer the capacity to pull the scalp, including the superficial musculoaponeurotic system, caudad. Clinically, this layering system poses opportunities for nerve entrapment as branches travel between layers. Compression or traction of the cranial and upper cervical spinal nerves that supply the scalp, muscle, fascia, and aponeurotica leads to headache and, potentially, visual disturbances. After giving off branches that supply the upper eyelid and mucosal lining of the frontal sinus, the supraorbital nerve pierces the frontalis muscle at variable levels from the orbital rim to the mid-forehead. It also courses through the galea aponeurotica to supply sensation to the skin, subcutaneous tissue, and periosteum of the scalp as far as the vertex of the skull.[3] The superficial branch of the supraorbital nerve travels along the BL channel and covers BL 3 and BL 4. Palpate the rostral cranium and forehead to determine the loci of tender sites and trigger points. Deactivate accordingly.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V_1):** Innervates the mucous membrane of the frontal sinus and upper eyelid (palpebral conjunctiva); supplies skin of forehead to the vertex.
- **Supratrochlear nerve (from frontal nerve, CN V_1):** Innervates the mucosal lining of the frontal sinus and the skin in the middle of the forehead.
- **Ophthalmic division (CN V_1):** Both the supraorbital and supratrochlear nerves arise from the frontal nerve, derived from the ophthalmic division of the trigeminal nerve. The ophthalmic division provides substantial numbers of pain-sensitive afferents for large portions of the supratentorial dura and its associated venous structures.[1] The ophthalmic division also appears to provide afferent sensory fibers to the main arterial trunks on the

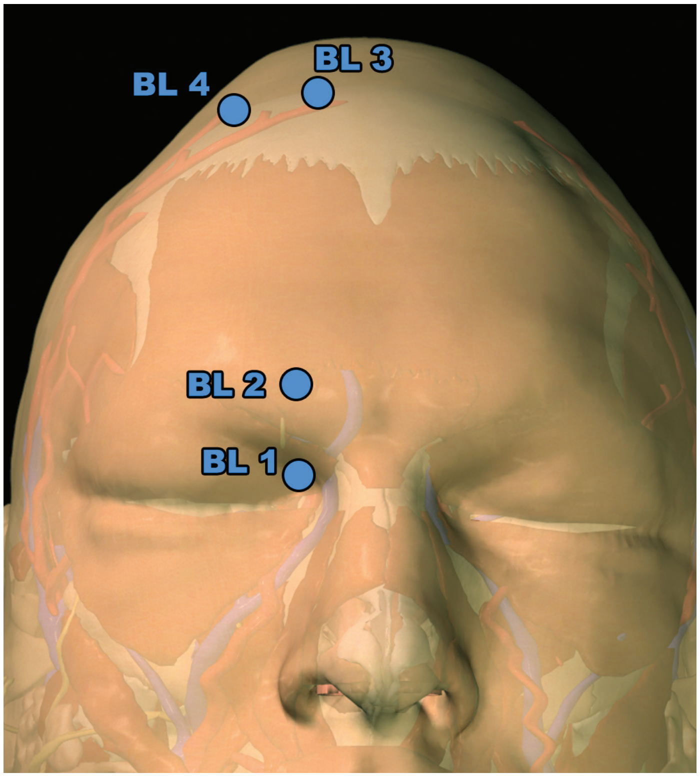

Figure 7-7. BL 2 and BL 3 trace the course of the supratrochlear and medial supraorbital nerves.

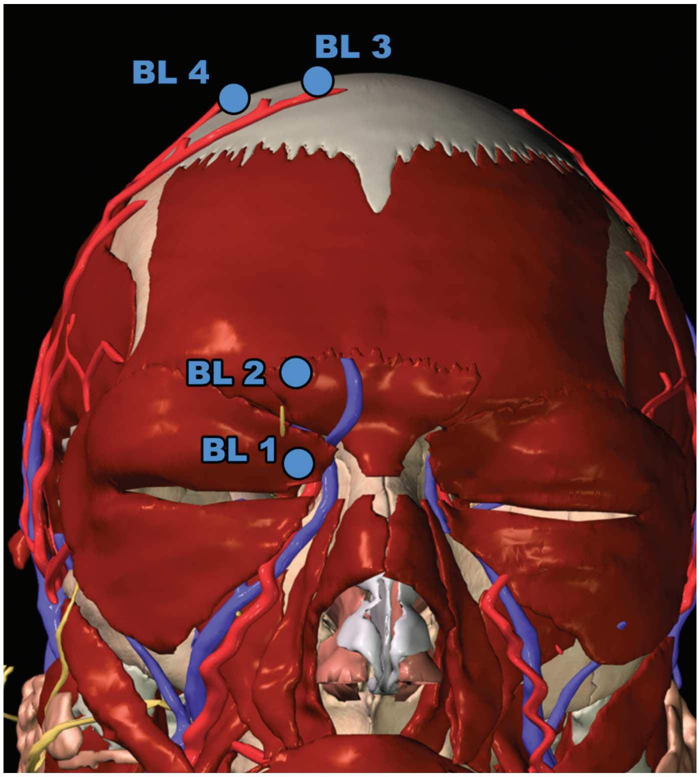

Figure 7-8. The frontalis muscle on the forehead, anchored at BL 3 and BL 4, elevates the eyebrows. Hence the name "Eyebrow Ascension".

base of the brain; i.e., the circle of Willis. Small branches from both the ophthalmic and maxillary divisions joint sympathetic fibers from the internal carotid artery to supply the vessels making up the circle of Willis. These connections provide an anatomic basis for headache-related indications of BL, GV, and other points in the trigeminal nerve distribution.

- **Temporal branch of the facial nerve, CN VII:** Innervates the superior part of the orbicularis oculi muscle and frontal belly of occipitofrontalis muscle.

Clinical Relevance: As becomes clear in Figure 7-9, the supratrochlear nerve peters out near BL 3. Consequently, the BL channel steps in a lateral direction to follow the supraorbital nerve to the vertex. Acupuncture at or near BL 3 addresses trigger point pathology and nerve entrapments involving the aforementioned nerves. Neuromodulation of the trigeminal nerve branches at BL 3 assists in clearing science congestion.

Vessels

- **Supraorbital artery:** Supplies the muscles and skin of forehead and scalp.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis structures. Figure 7-7 indicates the trajectory of the superficial temporal artery headed toward the midline. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

Indications and Potential Point Combinations

- **Nose and frontal sinus disorders, including rhinitis, sneezing, and sinusitis:** BL 3 or BL 4 (whichever is more tender), BL 2, GV 20, GV 24.5 (Yintang), LI 4, ST 36.
- **Frontal headache:** BL 3 or BL 4 if either is tender. Consider also BL 2, GV 20, GV 24.5 (Yintang), GB 14, LI 4.

BL 4

Qu Chai "Crooked Curve" or "Deviating Turn"

Located 1.5 cun lateral to the midline (at GV24), 1/2 cun posterior to the anterior hairline, level with BL 3 and GV 24. Lands 1/3 the distance from GV 24 to ST 8.

Muscles

- **Frontal belly of epicranius (occipitofrontalis) muscle:** Wrinkles the forehead, elevates the eyebrow.

Clinical Relevance: The occipitofrontalis muscle comprises two physiologically and anatomically distinct muscles.[1] The rostral limit of the galea aponeurotica in the vicinity of BL 3 and BL 4 creates a unique layering system that raises the possibility of nerve entrapment. That is, the superficial fascia over the occipital belly turns into the temporoparietal fascia that attaches to the superior, or upper, border of the frontalis muscle. This superficial musculoaponeurotic complex lifts the eyebrow and pulls the scalp rostrad. In contrast, the occipital belly of the occipitofrontalis muscle joins with the galea aponeurotica and inserts on the deeper aspect, or underside, of the frontalis muscle, forming the deep musculoaponeurotic system. The occipital muscle attachment gives this layer the capacity to pull the scalp, including the superficial musculoaponeurotic system, caudad. Clinically, this layering system poses opportunities for nerve entrapment as branches travel between layers. Compression or traction of the cranial and upper cervical spinal nerves that supply the scalp, muscle, fascia, and aponeurotica leads to headache and, potentially, visual disturbances. After giving off branches that supply the upper eyelid and mucosal lining of the frontal sinus, the supraorbital nerve pierces the frontalis muscle at variable levels from the orbital rim to the mid-forehead. It also courses through the galea aponeurotica to supply sensation to the skin, subcutaneous tissue, and periosteum of the scalp as far as the vertex of the skull.[2] The superficial branch of the supraorbital nerve travels along the BL channel and covers BL 3 and BL 4. Palpate the rostral cranium and forehead to determine the loci of tender sites and trigger points. Deactivate accordingly.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V$_1$):** Innervates the mucous membrane of the frontal sinus and the palpebral conjunctiva of the upper eyelid. Supplies the skin of the eyelid and forehead to the vertex. A sensory branch of the ophthalmic division of the trigeminal nerve.
- **Temporal branch of the facial nerve, CN VII:** Innervates the superior part of the orbicularis oculi muscle and the frontal belly of the occipitofrontalis muscle.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[3] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of BL 2, BL 4, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Supraorbital artery:** Supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis structures. Figure 7-7 indicates the trajectory of the superficial temporal artery headed toward the midline. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

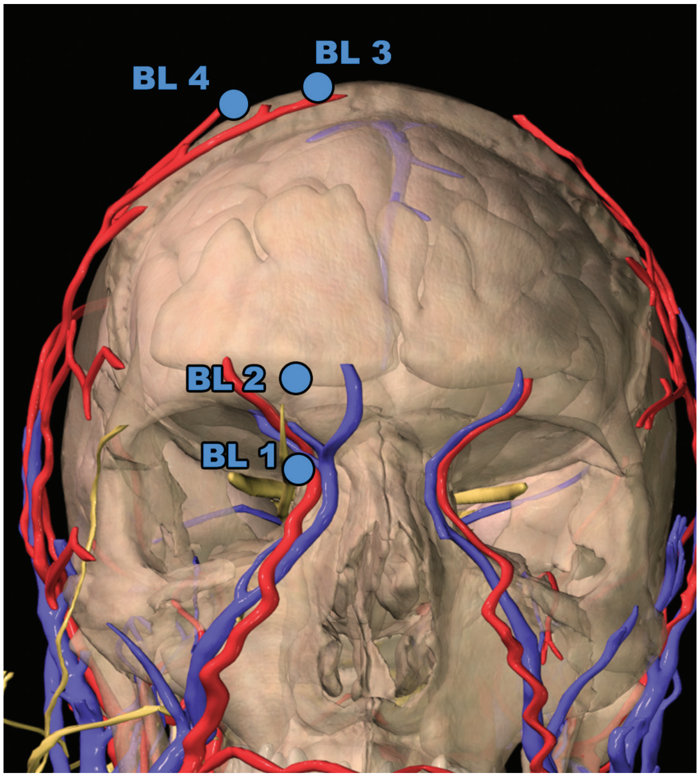

Figure 7-10. The BL channel turns a corner at BL 4, accounting for its name, "Deviating Turn". Its closest neural companion changes from the supratrochlear nerve at BL 3 to the supraorbital nerve from BL 4 to BL 7. See also Figure 7-9.

BL 5

Wu Chu "Fifth Place"

Located 1.5 cun lateral to the midline (at GV 23), .5 cun posterior to BL 4, and 1 cun behind the anterior hairline.

Muscles

- **Frontal belly of epicranius (occipitofrontalis) muscle:** Wrinkles the forehead and elevates the eyebrow.

Clinical Relevance: The occipitofrontalis muscle comprises two physiologically and anatomically distinct muscles.[1] The rostral limit of the galea aponeurotica in the vicinity of BL 3 and BL 4 creates a unique layering system that raises the possibility of nerve entrapment. That is, the superficial fascia over the occipital belly turns into the temporoparietal fascia that attaches to the superior, or upper, border of the frontalis muscle. This superficial musculoaponeurotic complex lifts the eyebrow and pulls the scalp rostrad. In contrast, the occipital belly of the occipitofrontalis muscle joins with the galea aponeurotica and inserts on the deeper aspect, or underside, of the frontalis muscle, forming the deep musculoaponeurotic system. The occipital muscle attachment gives this layer the capacity to pull the scalp, including the superficial musculoaponeurotic system, caudad. Clinically, this layering system poses opportunities for nerve entrapment as branches travel between layers. Compression or traction of the cranial and upper cervical spinal nerves that supply the scalp, muscle, fascia, and aponeurotica leads to headache and, potentially, visual disturbances. After giving off branches that supply the upper eyelid and mucosal lining of the frontal sinus, the supraorbital nerve pierces the frontalis muscle at variable levels from the orbital rim to the mid-forehead. It also courses through the galea aponeurotica to supply sensation to the skin, subcutaneous tissue, and periosteum of the scalp as far as the vertex of the skull.[2] The superficial branch of the supraorbital nerve travels along the BL channel and traverses BL 5. Palpate the rostral cranium and forehead to determine the loci of tender sites and trigger points. Deactivate accordingly.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V_1):** Innervates the mucous membrane of the frontal sinus and the palpebral conjunctiva of the upper eyelid. Supplies the skin of the eyelid and forehead to the vertex. A sensory branch of the ophthalmic division of the trigeminal nerve.
- **Temporal branch of the facial nerve, CN VII:** Innervates the superior part of the orbicularis oculi muscle and the frontal belly of the occipitofrontalis muscle.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[3] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of BL 2, BL 5, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Supraorbital artery:** Supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.
- **Deep temporal veins (tributaries of the pterygoid venous plexus):** Drain the deep parts of the scalp.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis structures. Figure 7-12 indicates the trajectory of the superficial temporal artery headed toward the midline. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves. The proximity of BL 5 to nearby deep temporal veins at the 10 o'clock and 11 o'clock positions (between the epicranial aponeurosis and dense connective tissue layers) is evident in Figure 7-13.

Indications and Potential Point Combinations

- **Frontal sinusitis, respiratory allergy symptomatology such as sneezing, rhinitis, and frontal headache:** BL 5 if tender; other tender points on the frontal region, BL 2, BL 10, GV 20, GV 24.5 (Yintang), LU 7, ST 36.

BL 6

Cheng Guang "Receiving Light"

Located 1.5 cun lateral to the midline, 2.5 cun behind the anterior hairline, and 1.5 cun posterior to BL 5.

Connective Tissues

- **Galea aponeuotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 7-13, labeled at the bottom right area of the image.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipialis (e.g., BL 9) muscles. Figure 7-14 depicts the relationship of BL 9 to the occipitalis muscle. Lateral pulls from the temporalis fascia accentuate tension in the epicranial aponeurosis and predisposes patients to headache syndromes.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V$_1$):** Innervates the mucous membrane of the frontal sinus and the palpebral conjunctiva of the upper eyelid. Supplies the skin of the forehead to the vertex.

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[1] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of BL 2, BL 6, and other points along the course of the supraorbital nerve alleviate neuropathic

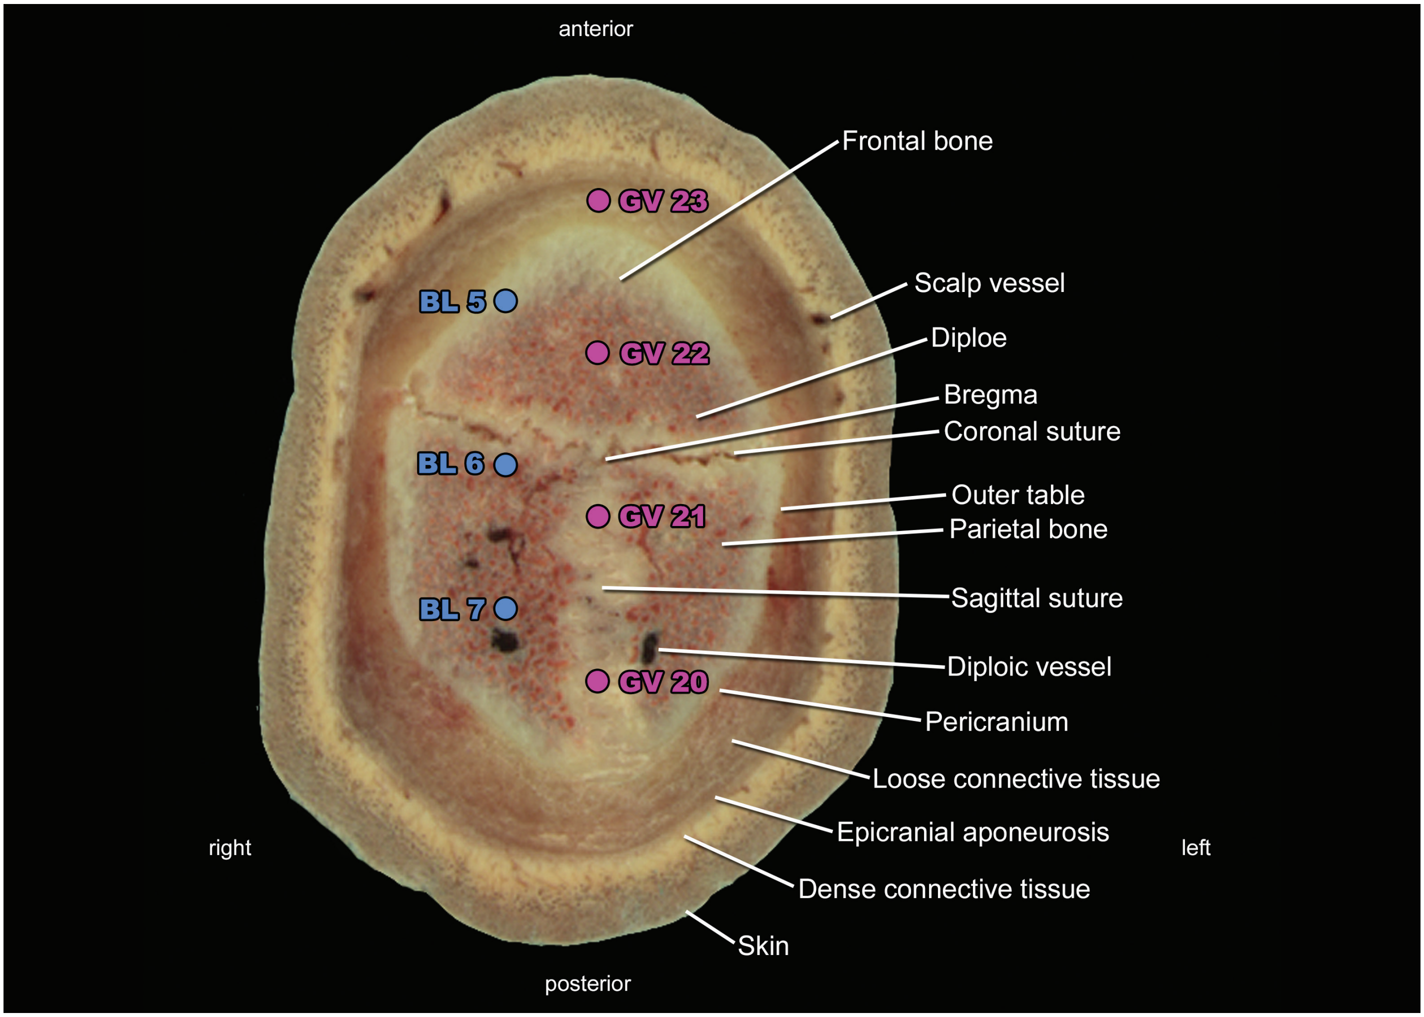

Figure 7-13. Light from the sun shines on BL 6, where "Receiving Light" exists (see also Figure 7-12 which highlights BL 6). Tenderness to palpation at BL 6 may arise from supraorbital neuropathy and/or restrictions in the coronal suture.

pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

Vessels

- **Supraorbital artery:** Supplies the muscles and skin of the forehead and scalp.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.
- **Superficial temporal artery (terminal branch of external carotid artery):** Supplies the skin and facial muscles of the frontal and temporal regions.
- **Superficial temporal vein (part of a widespread plexus of veins on the side of the scalp):** Drains the scalp, the superficial aspect of the temporal muscle, and the external ear.
- **Deep temporal veins (tributaries of the pterygoid venous plexus):** Drain deep parts of the scalp.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis vasculatre. Figure 7-12 indicates the trajectory of the superficial temporal artery headed toward the midline. Figure 7-14 echoes this phenomenon and reveals branches traveling to BL 7, BL 6, BL 5, and BL 4. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves. Figure 7-13 exposes the layout of deep vessels (“scalp vessel”) around the rostral cranium, between the epicranial aponeurosis and dense connective tissue.

Indications and Potential Point Combinations

- **Headache:** BL 6, other local points, GV 20, BL 10, LI 4.
- **Rhinitis:** BL 6, LI 4, LI 20, GV 24.5 (Yintang)

References

1. Mulero P, Guerrero AL, Pedraza M, et al. Non-traumatic supraorbital neuralgia: A clinical study of 13 cases. *Cephalalgia.* 2012. DOI: 10.1177/0333102412459575

BL 7

Tong Tian "Celestial Connection"

Located 4 cun behind the anterior hairline, 1.5 cun lateral to the midline, 1.5 caudal to BL 6, and 1 cun anterior to the level of GV 20. Because the distance between the glabella (and GV 24.5 or Yintang) and the lower border of the occipital protuberance (GV 16) equals 14 cun, BL 7 can be found at the midpoint of this line, 1.5 from the midline.

Connective Tissues

- **Galea aponeuotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 7-13, labeled at the bottom right area of the image.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipialis (e.g., BL 9) muscles. Figure 7-14 depicts the relationship of BL 9 to the occipitalis muscle. Lateral pulls from the temporalis fascia accentuate tension in the epicranial aponeurosis and predisposes patients to headache syndromes.

Nerves

- **Supraorbital nerve (from frontal nerve, CN V$_1$):** Innervates the mucous membrane of the frontal sinus and upper eyelid (i.e., the palpebral conjunctiva). Supplies the skin of the forehead to the vertex.
- **Spinal nerves C2 and C3:** Innervate the scalp caudal to the auricles; the dorsal roots of C2 and C3 innervate the caudal cranial fossa.
- **Greater occipital nerve (C2):** Supplies cutaneous sensation to the caudal scalp. Stimulation of the greater occipital nerve (GON) can reduce pain from headaches that arise in trigeminal nerve territory, possibly through mechanisms involving trigeminocervical convergence.[1]

Clinical Relevance: Supraorbital neuralgia (SON) produces headaches characterized by paroxysmal or constant pain in the medial region of the forehead. Patients complain of tenderness to palpation over the supraorbital notch/foramen and along the course of the nerve (which follows the BL channel) to the vertex.[2] Sensory dysfunctions associated with SON include hypoesthesia, parasthesia, and/or allodynia. Autonomic manifestations accompanying SON or concomitant trigger point pathology include conjunctival injection, lacrimation, or rhinorrhea, overlapping migrainous features exhibited in some patients, depending on the extent of vascular involvement through sympathotrigeminal reflexes. However, differential diagnoses for SON include trigeminal neuralgia in the ophthalmic division of the trigeminal nerve, hemicrania continua, or other trigeminal autonomic cephalalgias. SON differs from primary stabbing headache, nummular headache, and supratrochlear neuralgia by exhibiting tenderness to palpation over BL 2 (the supraorbital notch). Dry needling of BL 2, BL 7, and other points along the course of the supraorbital nerve alleviate neuropathic pain and trigger point contributions. Massage and other forms of manual therapy reduce pressure on the nerve along its course and empirically yield better outcomes than medication.

BL 7 may receive innervation from rostral filaments of the greater occipital nerve (as illustrated in Figure 7-12). As such, a compressed or otherwise irritated greater occipital nerve secondary to cervical spinal arthritis or head trauma could derive benefit from neuromodulation through acupuncture and related techniques at this site.

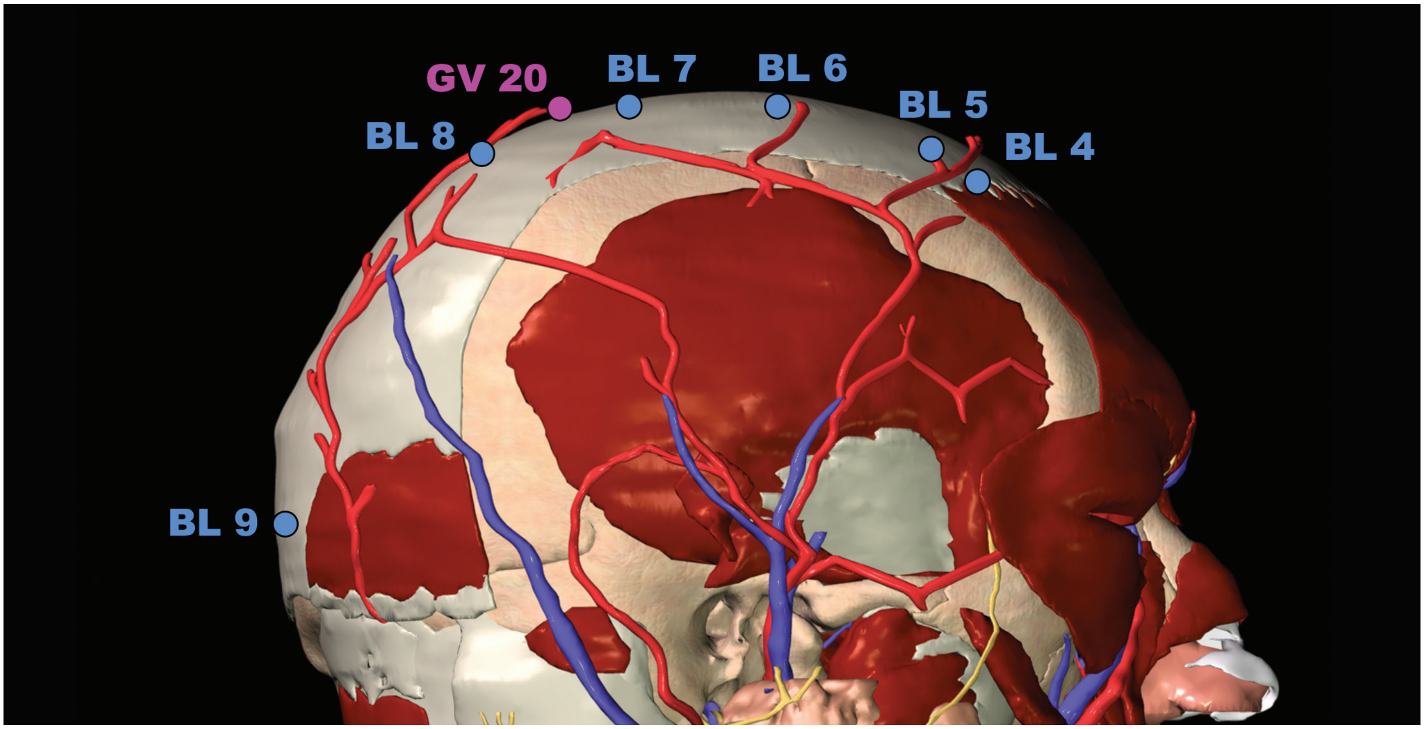

Figure 7-14. BL 7, the "Celestial Connection", is so named because of its relative proximity to the sky compared to other BL line points.

Functional connectivity between trigeminal and cervical afferents exists in the brain stem where afferent fibers from the three most cranial cervical spinal nerve roots converge onto neurons in the spinal nucleus of the trigeminal nerve.[3] This explains the widespread sensory, motor, and autonomic phenomena that arise in various headache states, including migraine and occipital neuralgia.

From a trigger point perspective, although muscles are largely absent from the vertex, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head, from BL 6 to BL 8. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature.

Vessels

- **Supraorbital artery:** Supplies the muscles and skin of forehead and scalp.
- **Supraorbital vein:** Drains the anterior part of the scalp and forehead.
- **Superficial temporal artery (terminal branch of external carotid artery):** Supplies the skin and facial muscles of the frontal and temporal regions.
- **Superficial temporal vein (part of a widespread plexus of veins on the side of the scalp):** Drains the scalp, the superficial aspect of the temporal muscle, and the external ear.
- **Deep temporal veins (tributaries of the pterygoid venous plexus):** Drain deep parts of the scalp.

Clinical Relevance: The supraorbital vessels anastomose with superficial temporalis vasculature. Figure 7-14 shows branches of the superficial temporal artery headed toward BL 7, BL 6, BL 5, and BL 4. Myofascial restriction in the occipitofrontalis and accompanying fascial planes compresses vessels against the skull, reducing tissue oxygenation and irritating nerves.

Indications and Potential Point Combinations

- **Nasal congestion:** BL 7, BL 6, GV 20, GV 24.5 (Yintang), LI 4, LI 20.
- **Headache:** BL 7 if tender, GV 20, BL 10, add BL 2 if frontal sinusitis, LI 4, LR 3.
- **Psychological disturbance:** agitation, attention deficit, insomnia, depression: BL 7, BL 8, GV 20. Alternate: Sishencong.
- **Vertigo:** BL 7 and/or BL 8, GV 20, BL 10, GB 20.
- **Seizures:** BL 7, BL 8, GV 20, ST 36.
- **Post-stroke hemiplegia:** BL 7, BL 6, GV 20, LI 4, ST 36, LR 3, Baxie (points located at the web spaces between the fingers), Bafeng (points in the web spaces between the toes).
- **Neck stiffness:** BL 7, BL 10, GB 21, GV 14.

BL 8

Luo Que "Declining Connection"

On the parietal region, 5.5 cun within the anterior hairline, 1.5 cun posterior to BL 7, and 1.5 cun lateral to the midline. Falls 1/2 cun posterior to the level of GV 20. Note that the distance between the midpoint of the anterior hairline and GV 20 equals 5 cun.

Connective Tissues

- **Galea aponeuotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Appears in Figure 7-13, labeled at the bottom right area of the image.

Clinical Relevance: Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipialis (e.g., BL 9) muscles. Figure 7-16 depicts the relationship of BL 8 to the galea aponeurotica. Lateral pulls from the temporalis fascia accentuate tension in the epicranial aponeurosis and predisposes patients to headache syndromes.

Nerves

- **Spinal nerves C2 and C3:** Innervate the scalp caudal to the auricles; the dorsal roots of C2 and C3 innervate the caudal cranial fossa.
- **Greater occipital nerve (C2):** Supplies cutaneous sensation to the caudal scalp. Stimulation of the greater occipital nerve (GON) can reduce pain from headaches that arise in trigeminal nerve territory, possibly through mechanisms involving trigeminocervical convergence.[1]

Clinical Relevance: The greater occipital nerve has been identified as a contributor to several types of headaches, including cluster, cervicogenic, migraine, medication-overuse, tension, and hemicrania continua.[2]

Functional connectivity between trigeminal and cervical afferents exists in the brain stem where afferent fibers from the three most cranial cervical spinal nerve roots converge onto neurons in the spinal nucleus of the trigeminal nerve.[3] This explains the widespread sensory, motor, and autonomic phenomena that arise in various headache states, including migraine and occipital neuralgia.

BL 8 receives innervation from the greater occipital nerve, as shown in Figure 7-15. As such, a compressed or otherwise irritated greater occipital nerve secondary to cervical spinal arthritis or head trauma could derive benefit from neuromodulation through acupuncture and related techniques at this site.

Figure 7-15. The innervation of the BL line shifts from predominantly trigeminal nerve-based (BL 1- BL 7) to the greater occipital nerve (BL 8 – BL 10), better addressing cervicogenic headaches than trigeminal-sourced discomfort. However, considering the convergence of upper cervical spinal nerve afferents onto the spinal nucleus of the trigeminal nerve, an anatomical basis exists for crosstalk occurring between nerves supplying both the rostral and caudal cranium. Furthermore, tension in the occipitofrontalis muscle worsens nerve irritation; relaxing both the occipitalis and frontalis with dry needling suggests treatment of rostral and caudal BL points.

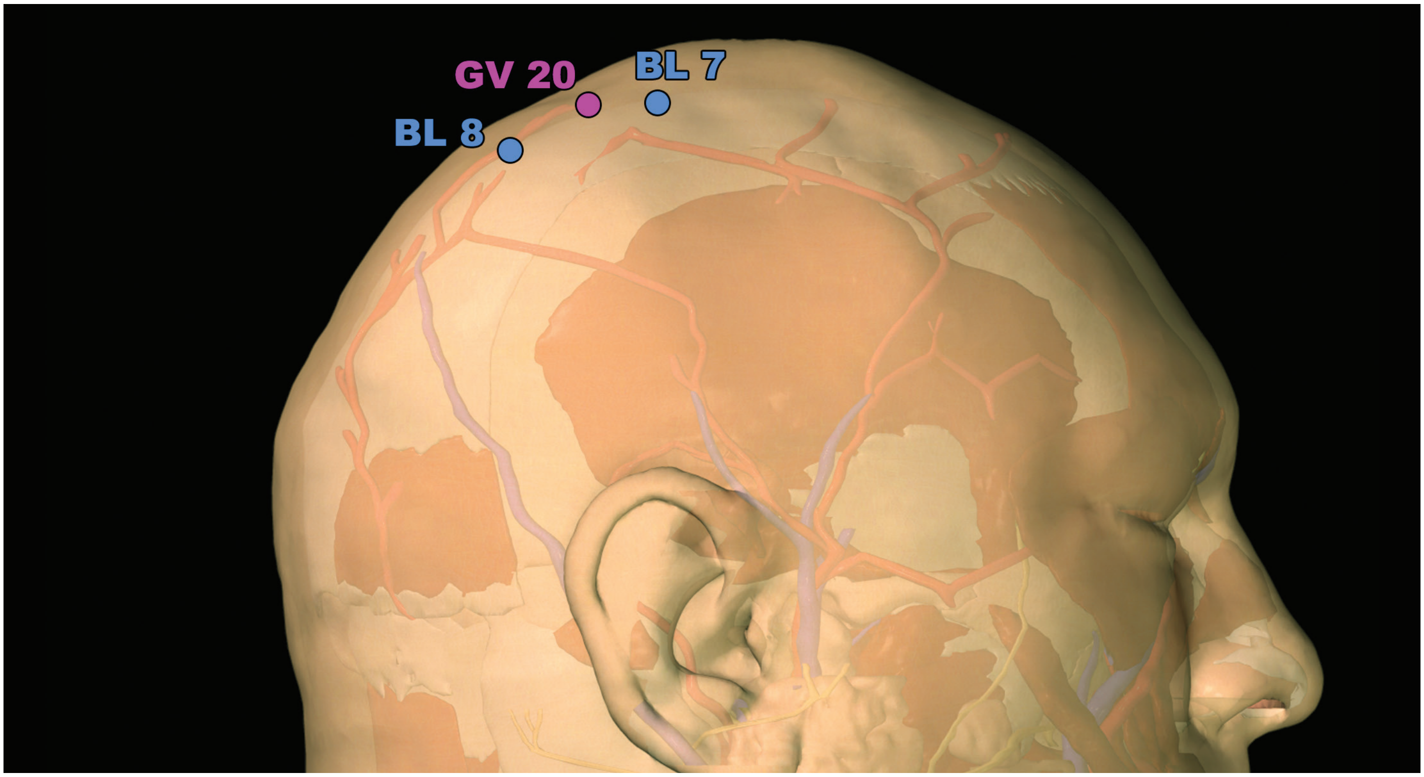

Figure 7-16. The descriptive name for BL 8, "Declining Connection" indicates its position below, BL 7, "Celestial Connection".

From a trigger point perspective, although muscles are largely absent from the vertex, dysfunction in the sternocleidomastoid (sternal head) and the splenius capitis sometimes refer pain to the top of the head, from BL 6 to BL 8. As such, patients presenting with vertex pain may be harboring trigger points in the cervical musculature.

Vessels

- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Drains the occipital portion of the scalp, and usually drains into the suboccipital venous plexus or the internal jugular vein.
- **Superficial temporal artery (terminal branch of external carotid artery):** Supplies the skin and facial muscles of the frontal and temporal regions. The arteries of the scalp, from both the external and internal carotid arteries, anastomose freely with one another in the dense, subcutaneous connective tissue layer of the scalp. This layer contains a rich innervation from the overlying cutaneous nerves. To review, branches of the external carotid artery that supply the scalp include the superficial temporal artery, the occipital artery, and the posterior auricular artery. Scalp arteries arising from the internal carotid artery include the supratrochlear and supraorbital arteries.
- **Superficial temporal vein (part of a widespread plexus of veins on the side of the scalp):** Drains the scalp, superficial aspect of the temporal muscle, and the external ear.
- **Deep temporal veins (tributaries of the pterygoid venous plexus):** Drain deep parts of the scalp.

Clinical Relevance: In addition to supplying the occipital scalp, the occipital arteries also contribute to the vascularization of the cervical paraspinal muscles.[4] Reduced blood supply due to myofascial restriction compressing vasculature predisposes the muscles served by those vessels to further pain and dysfunction.

Indications and Potential Point Combinations

- **Seizures**
- **Vertigo, dizziness**
- **Nasal congestion**
- **Migraine**
- **Vomiting**

BL 9

Yu Zhen "Jade Pillow"

On the occiput, in a depression approximately 1.5 cun lateral to the superior border of the external occipital protuberance. Located 1.3 cun lateral to GV 17, which lies in the depression superior to the external occipital protuberance, and 1.5 cun superior to GV 16. See Figure 7-17 to examine the relationship between BL 9, GV 17, and GV 16.

Connective Tissues

- **Galea aponeurotica (Epicranial aponeurosis):** Dense connective tissue linking the occipital and frontal bellies of the occipitofrontalis muscle. Tension from the galea aponeurotica onto or around nerves predisposes these vulnerable structures to entrapment syndromes. Treatment involves releasing connective tissue locally at locations such as BL 6, as well as deactivating trigger points in the frontalis (e.g., GB 14) and the occipitalis (e.g., BL 9) muscles. Figure 7-16 depicts the relationship of BL 8 to the galea aponeurotica. Lateral pulls from the temporalis fascia accentuate tension in the epicranial aponeurosis and predisposes patients to headache syndromes.

Clinical Relevance: BL 9 can become tender to palpation with occipitofrontalis tension (e.g., in cases of tension headache) that results in traction on the epicranial aponeurosis. BL 9 also becomes tender in some patients suffering from migraine and chronic neck pain. In addition, many muscles refer pain to the occipital region when they harbor trigger points. These muscles include the trapezius, sternocleidomastoid, semispinalis, splenius, suboccipital group, occipitalis, digastric and temporalis, according to Travell and Simon's *Myofascial Pain and Dysfunction – The Trigger Point Manual,* 2nd edition, p. 238.

Nerves

- **Spinal nerves C2 and C3:** Innervate the scalp posterior to the auricles; the dorsal roots of C2 and C3 innervate the posterior cranial fossa.
- **Greater occipital nerve (C2):** Supplies cutaneous sensation to the posterior scalp. Arises from the dorsal root of the second cervical spinal nerve. A communicating branch from C3 may join the GON. The nerve ascends in the caudal neck and head over the dorsal surface of the rectus capitis posterior major muscle. It pierces the fleshy fibers of the semispinalis capitis, runs a short distance rostrad and laterad but remains deep at this point to the trapezius muscle. It becomes subcutaneous just caudal to the superior nuchal line by passing above an aponeurotic "sling", close to the midline, consisting of the combined origins of the trapezius and sternocleidomastoid muscles, medial to the occipital artery.[4] (The occipital artery appears in Figure 7-17 lateral to BL 9.) As the GON passes through these various layers of muscle and fascia, the risk of entrapment increases.

Clinical Relevance: This region receives sensory nerve supply from the greater occipital nerve (GON). Crosstalk between the GON and the trigeminal nerve and windup in the trigeminocervical complex in the brainstem and cervical cord supports the inclusion of BL 9 in point protocols addressing intracranial and extracranial sources of discomfort.

Stimulation of the GON can reduce pain from headaches that arise in trigeminal nerve territory, likely through mechanisms involving trigeminocervical convergence at the level of the trigeminal nucleus caudalis.[1,5]

Neuromodulation of the GON can also help patients with chronic, or refractory, migraine.[6] While surgical implantation of nerve stimulators has been tried for patients with refractory headaches of various types such as migraine, hemicrania continua, post-traumatic causes, and cluster headache,[7] acupuncture represents a much less traumatic intervention that does not require generator or lead revision.[8,9]

In contrast to migraine, occipital neuralgia produces a paroxysmal, jabbing pain along the course of the GON or lesser occipital nerve, accompanied by reduced sensation or dysesthesia in the same region.[10] The involved nerves become tender to palpation; the problem resolves temporarily with injection of local anesthetic. Some patients experience migraine in conjunction with occipital neuralgia. Traumatic or degenerative craniocervical or upper cervical spinal disease predisposes patients to develop occipital neuralgia, as does referred pain from the ipsilateral trigeminal nerve distribution that impacts

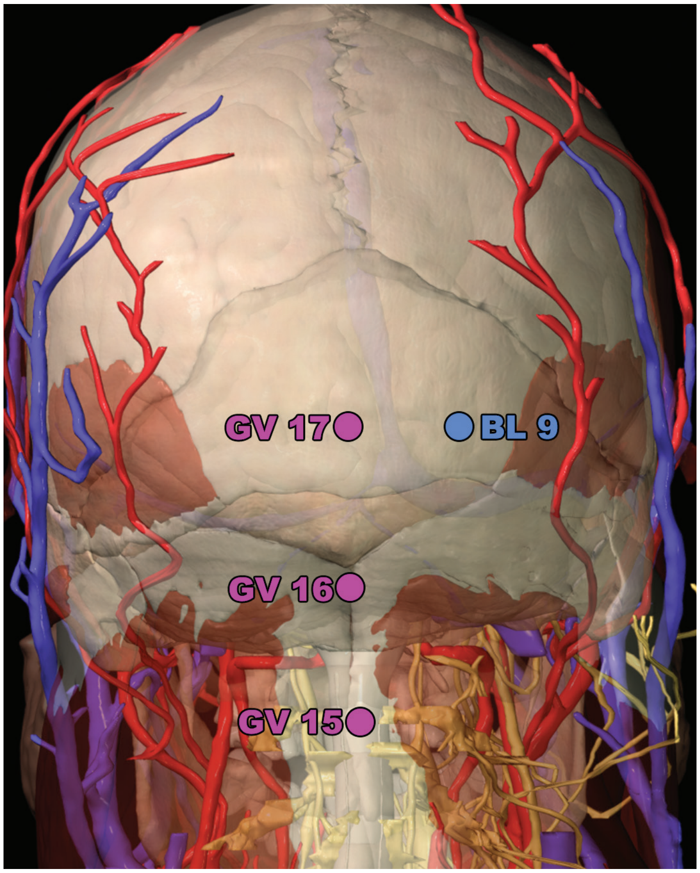

Figure 7-17. The Chinese word for the occipital bone, *zhen gu*, translates as "pillow bone",[2] referring to where the head contacts a pillow when lying recumbent, also thought of as "precious jade lying on a pillow".[3] This explains the name "Jade Pillow" for BL 9. It resides adjacent to GV 17 ("Brain's Door"), shown on the midline, level with BL 9. The semi-transparent skull affords the opportunity to visualize the sagittal sinus veering toward the right, away from midline. BL 9 relates closely to the greater occipital nerve (GON), not shown in this image but which courses medial to the greater occipital artery which is visible lateral to "Jade Pillow".

the C2 spinal cord segment through crosstalk between the spinal nucleus of the trigeminal nerve and the C2 spinal nerve root. Blocking the GON with local anesthetic can diagnose and treat occipital neuralgia, but complications are possible. These include injection of local anesthetic into the artery, a Cushingoid response to serial injections of corticosteroids, and cerebral injury if patients have a pre-existing cranial defect from prior surgery or trauma.[11] Surgical procedures capable of inducing postoperative occipital neuralgia include the C1 lateral mass screw insertion for stabilization of the atlantoaxial joint.[12]

Vessels

- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Usually drains into the suboccipital venous plexus or the internal jugular vein.

Clinical Relevance: The occipital artery is often a main feeding artery in cases of intracranial dural arteriovenous fistulae.[13] Also, blunt, penetrating, or iatrogenic trauma, infectious illness and autoimmune disease can cause scalp aneurysm involving the occipital artery.[14] In that aneurysms of the artery present as painless swellings, avoid acupuncture needling of any scalp mass other than trigger point pathology.

Indications and Potential Point Combinations

- **Tension headache, neck pain and myofascial restriction:** BL 9, BL 10, GV 20, GV 24.5, GB 21.
- **Migraine:** BL 9, BL 10, GV 20, GB 21, LI 4, ST 36, LR 3, appropriate trigger points.
- **Occipital neuralgia:** BL 9, BL 10, GB 14, GV 20. Myofascial release to the neck. Deactivation of relevant trigger points, especially in the cervical paraspinal and upper back region, including the trapezius.[15]
- **Vertigo, dizziness due to cervicogenic causes:** BL 9, BL 10, GB 20, LI 4, cervical and upper back trigger points.
- **Vertigo due to vertebrobasilar artery insufficiency:** BL 9, GV 20 directed toward GV 21, GB 8, and GB 7.[16]
- **Visual problems:** BL 9, BL 10, BL 2, GB 1.
- **Nasal congestion:** BL 9, BL 10, GV 20, LI 20.

Evidence-Based Applications

- A Chinese study reports benefit for the treatment of spasticity in infants with **cerebral palsy** by needling BL 9 and BL 10, designed to influence the “superficial projection region of the pyramidal decussation”.[17]

BL 10

Tian Zhu "Celestial Pillar"

In a depression on the lateral border of the trapezius muscle, level with the caudal border of the spinous process of C2. Figure 7-19 illustrates how BL 10 falls along the border of the trapezius while Figure 7-20 presents its proximity to C2. While some authors place BL 10 more cranial (superior), the risk of damage to the vertebral artery increases in a suboccipital location.

Muscles

- **Trapezius muscle:** Fibers of the cranial, or superior, part of the trapezius elevate the scapula (i.e., when shrugging the shoulders).
- **Splenius capitis muscle:** Acting unilaterally, this muscle rotates the head at the atlantoaxial joint; it laterally flexes the head and neck to the same side. Acting bilaterally, these muscles extend the head and neck. Myofascial
- **Semispinalis capitis muscle (a transversospinal muscle):** Extends the head.
- **Longissimus capitis muscle:** Medial to the longissimus cervicis and lateral to the semispinalis capitis muscle, the longissimus capitis arises from tendons attached to the transverse processes of the 4-5 most cranial thoracic vertebrae and articular processes of the 3-4 most caudal cervical vertebrae. It inserts onto the caudal margin of the mastoid process of the temporal bone, caudal to the splenius capitis and sternocleidomastoid insertion. Extends the neck and head when active bilaterally; rotates and laterally flexes the head and neck when contracted unilaterally.

Clinical Relevance: Myofascial trigger points in any of these muscles can produce head and neck pain. In addition, pain at the back of the head can arise from trigger points in the multifidi, levator scapulae, splenius cervicis, and infraspinatus muscles. Restriction in the soft tissues in the neck elevates pressure on large, vital neural, vascular, and glandular components, raising the potential for pain and suboptimal endocrine regulation.

Nerves

- **Third ("Least") occipital nerve (C3):** Innervates the skin of the medial occipital and cervical regions. This dorsal ramus of the C3 spinal nerve separates into a complex system of branches after emerging from the articular pillar of the C3 vertebra. It divides into medial and lateral branches, with the medial further separating into deep and superficial divisions.[11]

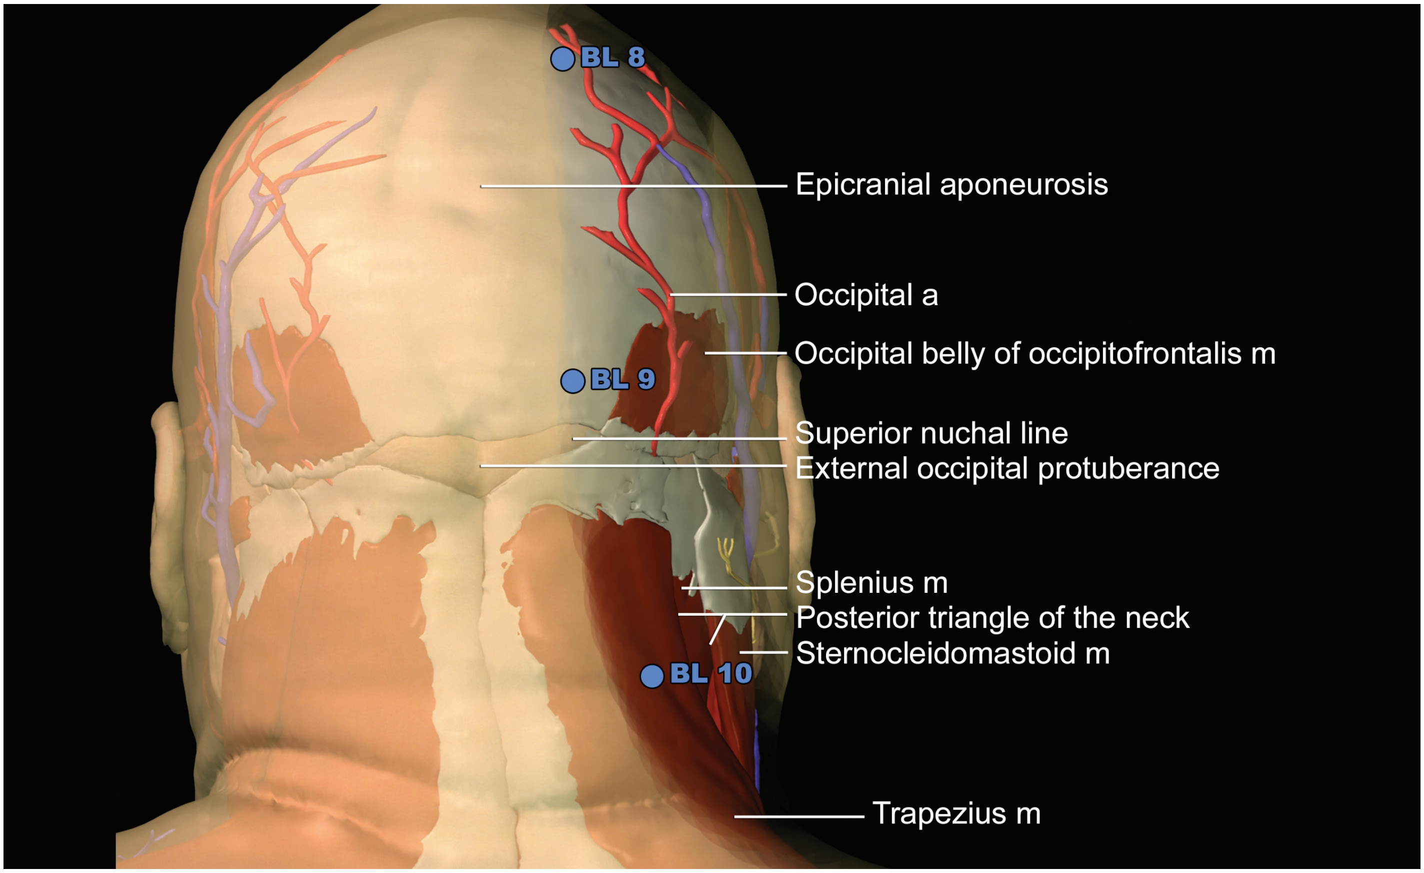

Figure 7-19. As the BL channel descends the neck and back, it begins to interface more closely with spinal nerves influence or initiate neck and back pain when neuromodulated or irritated, respectively. BL 10, "Celestial Pillar" sits at a fulcrum between the head and back and as such addresses all three: head, neck, and back pain. It does so by impacting cervical spinal nerves that form the GON, leading to headache and by myofascial components that produce both neck and head pain, such as the trapezius muscle. The cranial extent of the erector spinae, or epaxial, muscles, inserts onto the occiput. When tense, this column of myofascial bands connecting the occiput to sacrum entraps a host of spinal nerve branches, leading not only to pain but to restricted motion and altered supporting function. This image takes away the skin layer to expose the structures beneath the BL pathway from BL 8 to BL 10.

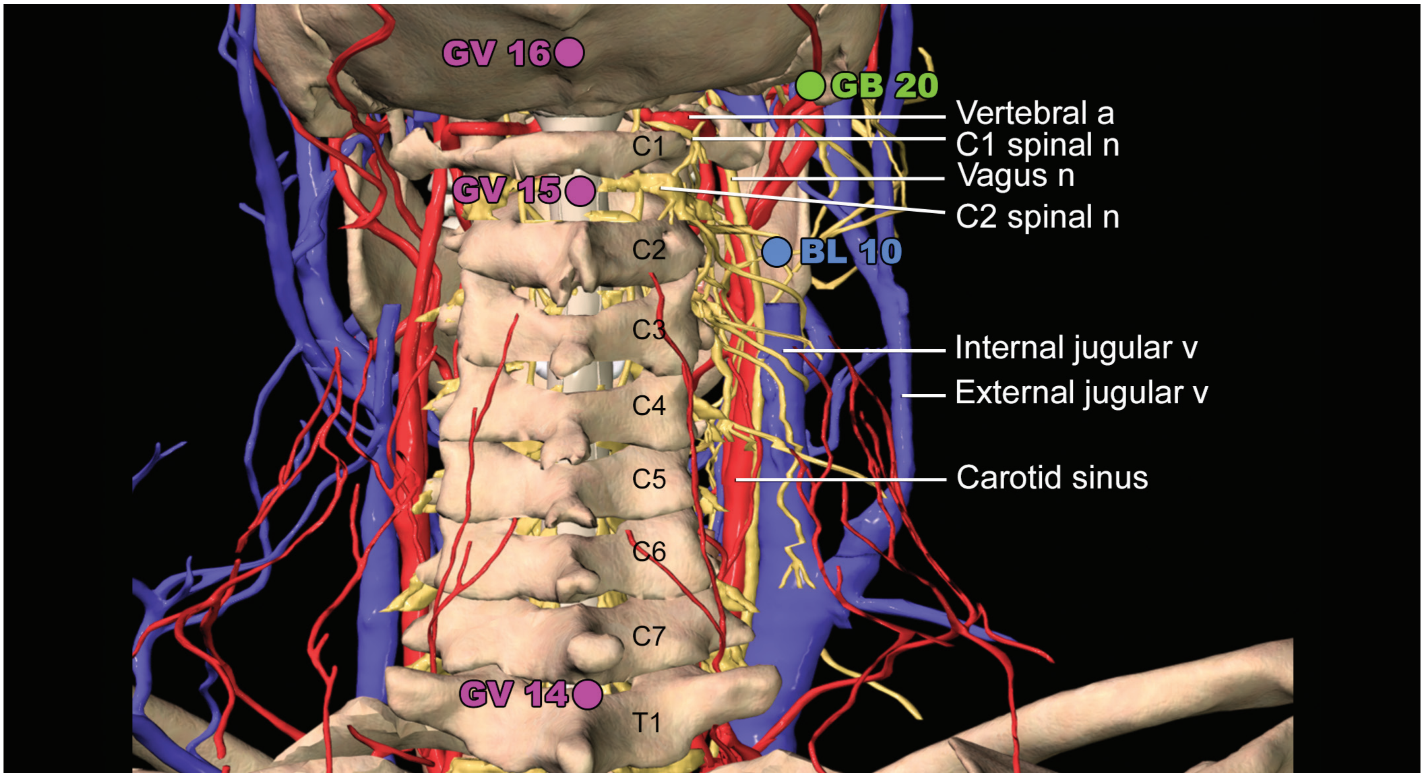

Figure 7-20A. BL 10, "Celestial Pillar", stands at the top of the pillar (neck) that supports the heavens (head).

- **Greater occipital nerve, or GON (C2, C3):** Innervates skin of the upper neck and occipital regions, lateral to the 3rd (least) occipital nerve.
- **Spinal nerve C2-C3, dorsal rami:** Innervate the posterior cranial fossa.
- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **Spinal nerves C2 – C5, dorsal rami:** Innervate splenius capitis muscle.
- **Spinal nerves C2 – C4, dorsal rami:** Innervate semispinalis capitis muscle.
- **Spinal nerves C4 – C7, dorsal rami:** Innervate longissimus capitis muscle.

Clinical Relevance: Any of the nerves supplying structures within reach of a needle entering BL 10 may become entrapped in the series of layers involved in cervical anatomy, apparent in Figure 7-22. Nerve entrapment leads to pain and myofascial dysfunction. The GON headed from BL 10 toward GV 20, has received the most intensive attention based on its contribution to headaches of all sorts, including migraine (see below).

GON: Convergence between the cervical nerves and trigeminal inputs provides a strong neuroanatomic context supporting the inclusion of points within the upper cervical and trigeminal nerve distribution for head and face pain.[1] This trigemino-cervical convergence can work in a nociceptive excitatory or inhibitory manner, depending on the nature of the stimulation entering the central nervous system. The trigemino-cervical complex forms the anatomic and physiologic basis for this convergence.[2] The complex spans from the trigeminal nucleus caudalis to the C2 and C3 spinal cord segments. The GON provides afferent information from the posterior head to the complex, mainly through the C2 nerve root. Nociceptive input supplied by upper cervical nerves flowing into this neural intersection include afferent stimuli from blood vessels, the dura mater of the posterior cranial fossa, cervical spinal ligaments, joints, and muscles. Furthermore, a direct coupling takes place in the dorsal horn of the spinal cord between cervical afferents and input from the meninges, arguing again for targeting cervical acupuncture points (in addition to points innervated by the trigeminal nerve) in cases of head pain and dural irritation. Chronic pain states that induce neuroplastic changes and central sensitization accentuate the excitability of the synaptic meetings, leading to mutual changes and upregulation in the firing patterns of structures in the trigeminocervical distribution. Neck muscles may tense as a result of the sensorimotor integration facilitated by the

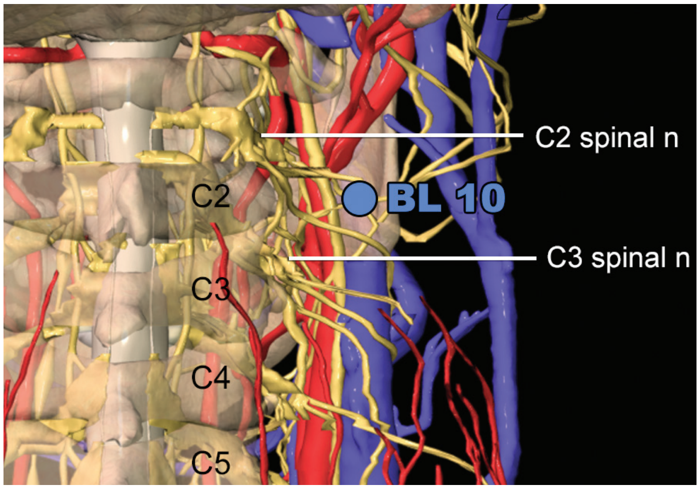

Figure 7-20B. This enlargement of the C2 and C3 spinal nerve branches exiting the intervertebral foramina illustrates the complex branching pattern of the C2 and C3 spinal nerves, including fibers supplying the cervical facet joints.

Figure 7-21. The high volume of neural traffic entering and exiting from the upper cervical nerve roots becomes clear in this image focusing on the spinal cord, nerves, and autonomic routes. Note the proximity of BL 10 to the vagus nerve, vertebral artery, and superior cervical sympathetic ganglion.

central sensitization resulting from chronic nociceptive afferent aggravation of pain pathways. Heightened motor output through alpha- and gamma-motoneurons secondarily activates Ia and II muscle spindle afferents, producing even more motor tone through spinal reflex mechanisms. Irritated dural nociceptors further push the motoneurons to fire, contracting the suboccipital paraspinal muscles. Neuromodulation with acupuncture affects local and central pain modulation circuits and interrupts these reflexes. It reduces central sensitization and muscle tension and improves circulation to the local musculature, thereby reducing nociceptive afferent irritability.

Trigeminocervical neural crosstalk can cause patients to feel pain driven by nociceptive information from structures supplied by upper cervical nerve roots and trigeminal territories. This may confuse where the pain originated in cases of posterior fossa tumor, infratentorial dura mater, neuropathic cervical nerve roots, disturbances in the subcutaneous tissue supplied by the GON, and dissection of the vertebral artery.[3]

Cervical spinal nerves: Cervical zygopophysial joints cause chronic neck pain and headache in up to half of patients. Facet joints receive innervation from the medial branches of the spinal nerves C3 to C7; each nerve supplies the joint above and below. BL 10 lives near the location of a third (least) occipital nerve block.[12]

Although percutaneous radiofrequency ablation (RFA) has become an accepted nonsurgical modality for chronic neck pain, serious advents may occur. RFA of the least (3rd) occipital nerve and the C2-C4 facet joints has led to “dropped head syndrome” in which the patient became unable of extending her neck, inducing a debilitating complication.[13] While acupuncture and related techniques may not be able to repair nerves completely destroyed by RFA, the risk of permanent disability emphasizes the need to address pain and functional compromise with safe and effective approaches such as acupuncture and related techniques before pursuing modalities that can cause irreversible damage.

Third occipital nerve (TON): This dorsal branch of the 3rd cervical spinal nerve must make its way through several layers of deep nuchal musculature, raising the potential for nerve entrapment and irritation. Thus, this nerve likely produces occipital neuralgia more than has been previously recognized.[14] Neuralgia originating from TON disorders mimics GON neuralgia. The superficial medial branch of the C3 spinal nerve, also called the 3rd or least occipital nerve, travels around the dorsolateral surface of the C2-3 zygopophysial (facet) joint that it supplies. The site of this nerve branching is at BL 10. While facet joints caudal to C2-3 receive innervation by the dorsal rami above and below the joint, the C2-3 facets only receive TON innervation. After supplying the facet joint, the TON continues on to supply the semispinalis capitis muscle, traveling deeply along this muscle until it sends a communicating branch to the greater occipital nerve. The risk of third occipital neuralgia increases as a result of its vulnerability to entrapment at the level of the intervertebral disk behind the intervertebral joints. Osteophytes in these joints can produce nerve compression and chronic headache that may remain undiagnosed as a result of clinicians’ unfamiliarity with this nerve entrapment syndrome. Review the proximity of BL 10 to the anatomy just discussed in Figure 7-20.

Craniotomies with midline approaches may also damage or irritate the TON and cause occipital neuralgia after suboccipital approaches. Scar tissue envelops the nerve, compressing its branches; pain sometimes worsens with cervical motion and mounting myofascial restriction. Intraoperative traction applied to deeper facet branches of the TON during midline craniotomy

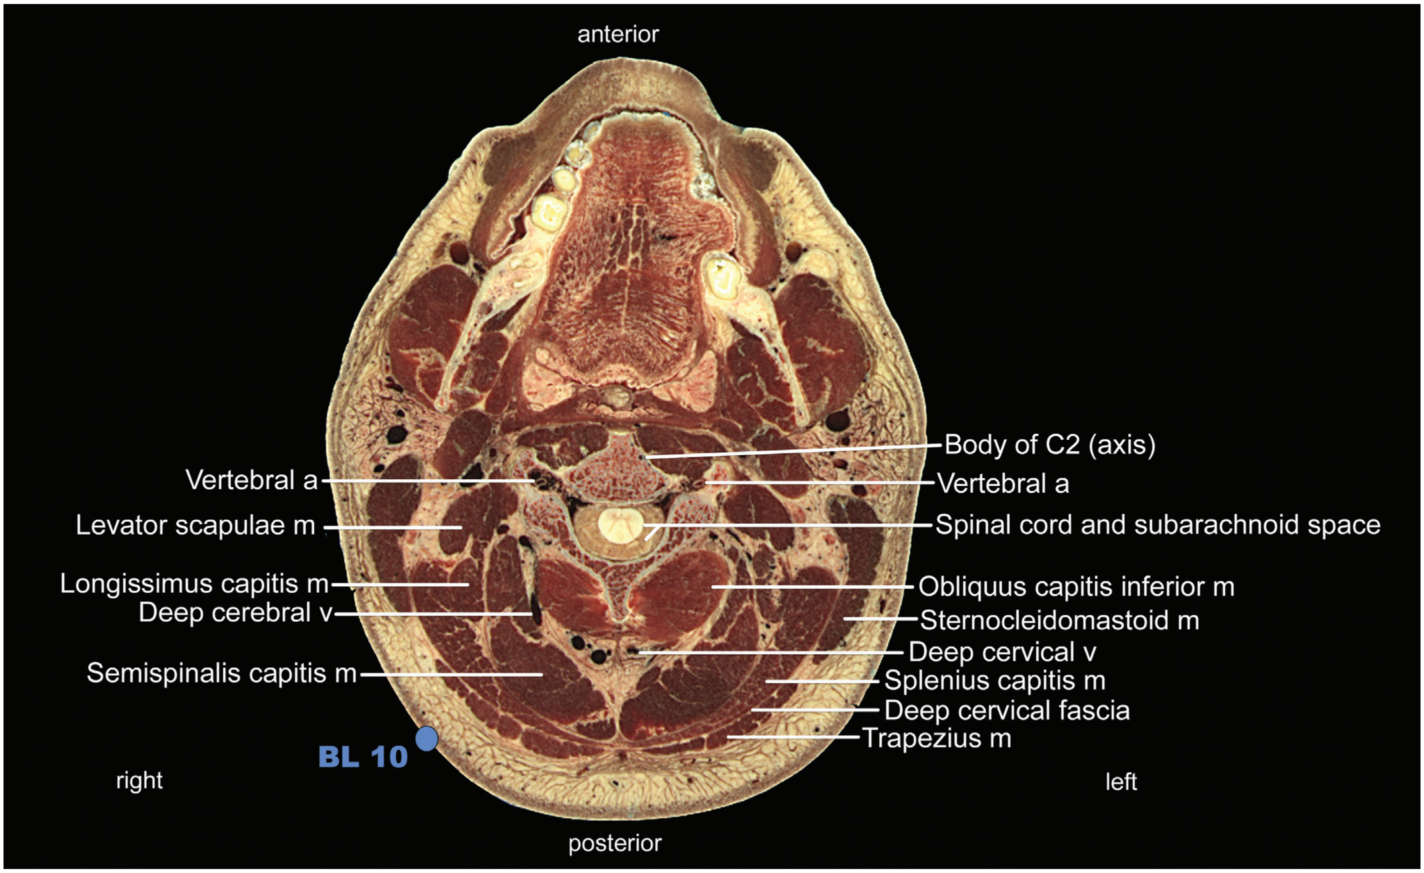

Figure 7-22. This cross section at the level of C2 gives a good perspective of the multilayered musculature where numerous trigger points may entrap nerves and cause local and/or referred neck pain. It also reveals the notable vascular structures which deep needling could damage; i.e., the deep cervical veins and the vertebral artery.

damages its deeper facet branches. Acupuncture and related techniques carefully at BL 10, GV 15, and GV 16 can release tension in this region and neuromodulate the TON.

Vessels

- **Occipital artery (a branch of the external carotid artery):** Supplies the scalp at the back of the head.
- **Occipital vein:** Usually drains into the suboccipital venous plexus or the internal jugular vein.
- **Deep cervical artery (from the costocervical trunk, which arises from the subclavian artery):** Supplies the deep cervical muscles.
- **Deep cervical vein:** Receives tributaries from the plexuses around the spinous processes of the cervical vertebrae, and terminates in the lower part of the vertebral vein.

Clinical Relevance: Deep cervical vessels, seen in Figure 7-20 ascending the dorsal surface of the vertebral bodies, are vulnerable to damage with dorsal approaches to cervical spinal surgery.[15] Acupuncture and related techniques such as laser therapy can restore blood supply to the tissues whose perfusion was compromised by invasive procedures to the spine.

Indications and Potential Point Combinations

- **Neck pain, restricted motion, and muscular tension:** BL 10, BL 9, GB 21, other pertinent myofascial trigger points (check on anterior, lateral, and posterior surfaces of the head and neck), GV 20.
- **Occipital headaches:** BL 10, BL 9, GV 14, GV 20.
- **Acute lumbar strain:**[16] BL 10, BL 23, BL 40, BL 60.
- **Post-craniotomy occipital neuralgia:** Laser therapy to BL 10, GV 15, GV 16, GB 20.
- **Shoulder and back pain:** BL 10, GB 20, GB 21, local myofascial trigger points and BL points associated with the vertebral levels of somatic dysfunction, accounting for the divergent input entering the cord a few levels above and below the dysfunction.
- **Vertigo, dizziness, heavy feeling in the head:** BL 10, GB 20, GB 21, check TMJ for myofascial trigger points, LI 4.
- **Memory and concentration problems:** BL 10, BL 7, BL 8, GV 20.
- **Problems with visual acuity:** BL 10, BL 2, BL 9, GV 16, GV 20, GV 24.5 (Yintang). Also check for trigger point in the splenius muscle, because myofascial trigger points here can produce blurry vision, headache, and eye pain that feels "bursting".[4] Eye pain often occurs on the ipsilateral side of the trigger point.[5]
- **Trigeminal neuralgia, post-herpetic neuralgia, and other causes of neurogenic facial pain:**[6] BL 10, points associated with trigeminal nerve branch transmitting pain, myofascial trigger points in the region, GV 14, GV 20.

Evidence-Based Applications

- Prophylactic use of bilateral noninvasive acuplaster on BL 10, BL 11, and GB 34 significantly reduces **vomiting** in children after strabismus correction.[7]

- Three out of three RCTs supported effectiveness of acupuncture for the treatment of **temporomandibular disorders,** prompting the following treatment recommendation: ST 6, ST 7, SI 18, GV 20, GB 20, BL 10, and LI 4.[8]
- A case series indicated that needling and point injection at BL 10 relieved **acute lumbar sprain.**[9]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[10]
- **Transient cerebral ischemic attack:** A Chinese study reported the success of acupuncture at BL 10, GB 12, and GB 20 to reduce symptoms from TIA and improve blood rheology and coagulation with the help of leech and centipede capsules.[17]
- **"Mind-refreshing acupuncture" to treat facial spasm, trigeminal neuralgia, and facial paralysis:** BL 10, GB 12, and GB 20, along with GB 23 and Yintang to improve blood flow in the vertebrobasilar artery and increase cerebral blood flow by reducing tension in the vascular smooth muscle.[18]
- **Balance disorders after whiplash injury:** Dry needling of BL 10 and GB 20 led to significant improvements in patients experiencing balance disorders following cervical torsion/whiplash injury.[19]

BL 11

Da Zhu "Great Shuttle"

On the upper thorax, about 1.5 cun lateral to the caudal border of the T1 spinous process.

CAUTION: Needle carefully to avoid pneumothorax. Note the presence of lung tissue near BL 11 in Figure 7-23A. Figure 7-24, in contrast, reveals the thick musculature beneath BL 11 in this individual. Needling BL 11 poses a higher risk of pneumothorax in thin, poorly muscled, and/or geriatric patients, especially when the direction of insertion places the tip between the ribs and away from midline.

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a posterior direction).
- **Rhomboideus major and minor muscles:** Retract and rotate the scapula; assist the serratus anterior muscle in holding the scapula against the thoracic wall; hold the scapula in place the scapula while the thoracic limb is moving.
- **Serratus posterior superior muscle:** Elevates the upper four ribs, thereby raising the sternum and increasing the anteroposterior diameter of the thorax.
- **Erector spinae muscles (transversospinalis, longissimus thoracis, and iliocostalis thoracis muscles):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Trigger points in the vicinity of BL 11 include: splenius cervicis, radiating to the junction between the neck and shoulder; levator scapulae, producing pain locally and radiating to the medial scapula and dorsal shoulder; and rhomboids sending pain along the entire medial border of the scapula. Note the differences in appearance between the axial and appendicular musculature in Figure 7-24, where the musculature attaching to the spine has a much different appearance than those attached to the appendicular skeleton that are less condensed and lighter in color. Figure 7-23B also lends insight into the structural disparity between the broad, more superficial muscular layers (consisting mainly of the trapezius muscle in this presentation) as opposed to the column of erector spinae following and defining the BL channel.

Acupuncture, massage, and laser therapy loosen restrictions that collect here, improving perfusion and reducing peripheral sensitization.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **C4, C5, T1 and T2 spinal nerves:** The dorsal rami innervate skin, bones, joints, muscles of the back. The ventral rami form intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **Dorsal s capular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5

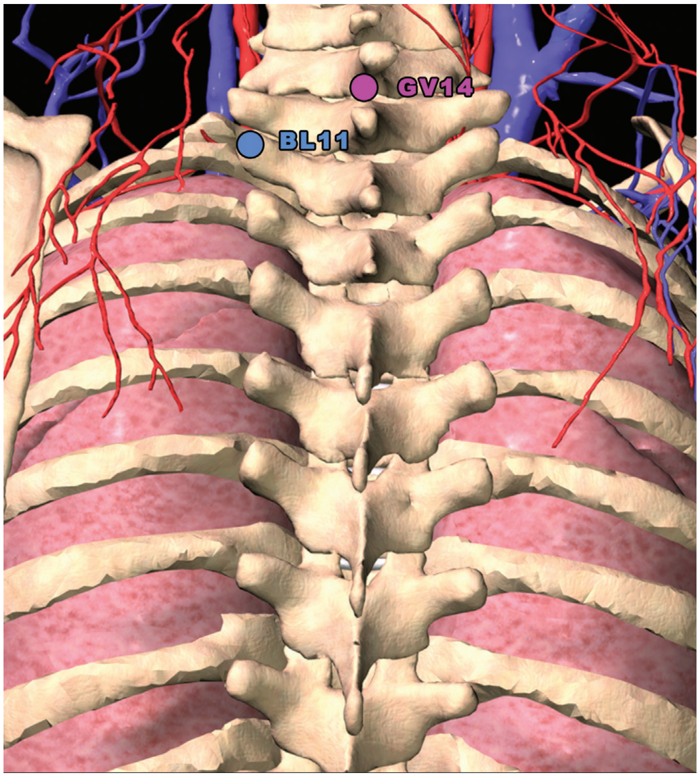

Figure 7-23A. The term "Great Shuttle" applies to the way in which the vertebrae resemble a weaver's shuttle coursing to and fro between the ribs. The spinous process of T1 outsizes that of the other thoracic vertebrae, earning it the "great" shuttle status. Not surprisingly, the nearby point GV 14 goes by the name "Great Hammer" for similar reasons.

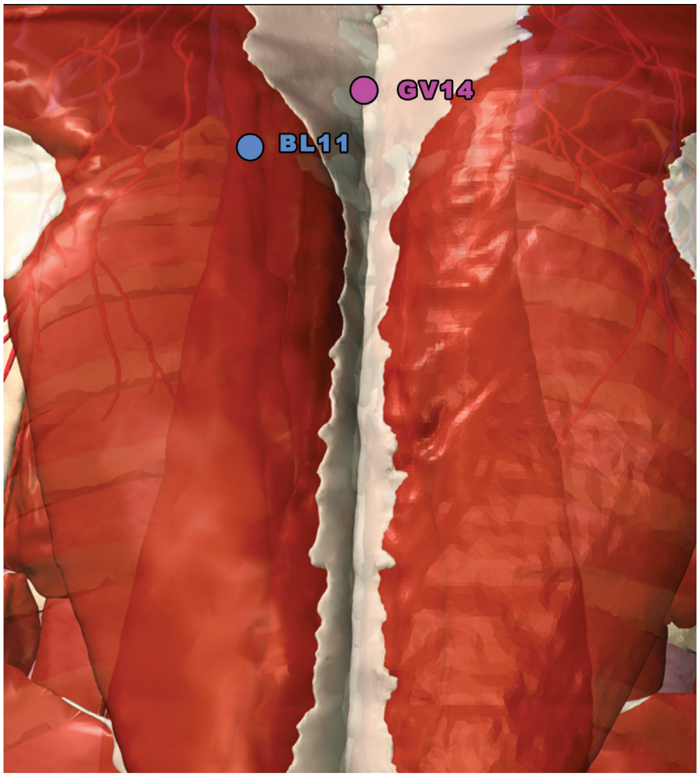

Figure 7-23B. This multilayered image discloses the position of BL 11 atop the paraspinal muscles and well within the "Bermuda Triangle" of trigger points between the medial angle of the scapula and the neck.

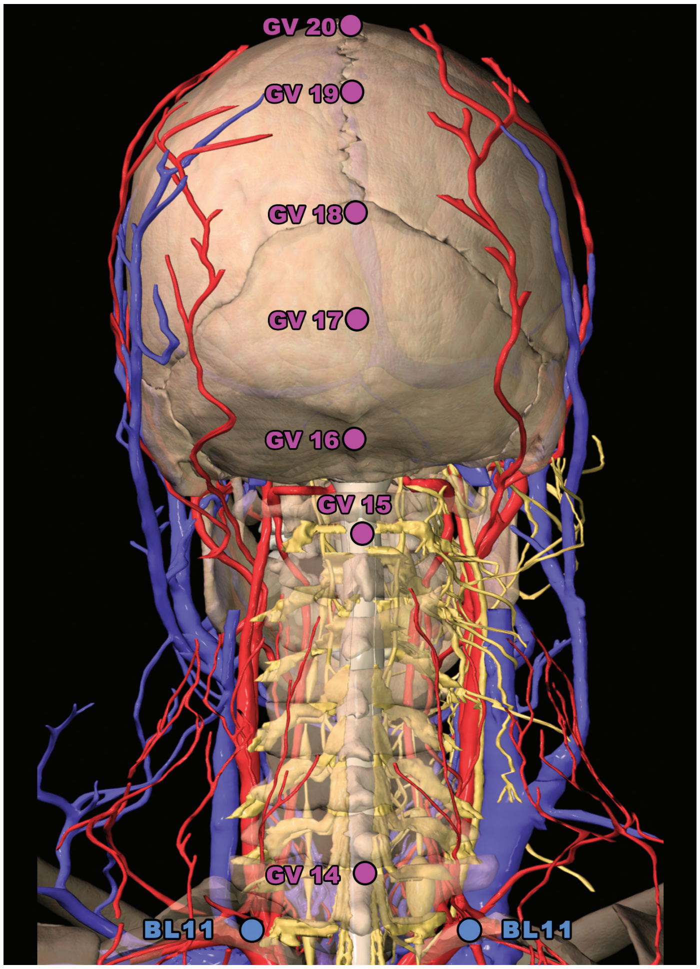

Figure 7-23C. BL 11 begins the BL point series spanning the thorax, lumbar region, and sacrum. Each BL point impacts the adjacent spinal nerve, inducing direct effects on erector spinae tension, pain, and perfusion in the paraspinal musculature. When afferent input reaches the spinal cord communication between somatic and visceral pathways may modulate activity in organs and other structures innervated by that same or nearby spinal cord segments. This forms the basis of diagnostic and treatment approaches through the Shu – Mu subsystem of points, with the twelve Shu points derived from locations on the BL channel between BL 13 and BL 28.

and often receives contribution from C4. May provide fibers to the levator scapulae muscle.

- **T2-T5 spinal nerves, ventral rami (2nd to 5th intercostal nerves):** Innervate the serratus posterior superior muscle.
- **Cervicothoracic (stellate, inferior cervical sympathetic, or caudal cervical sympathetic) ganglion:** A sympathetic ganglion formed by the fusion of the caudal cervical and first thoracic sympathetic ganglia. The cervicothoracic ganglion sits at the level of C7, ventral to the C7 transverse process and neck of the first rib, dorsal to the subclavian artery. See Figure 7-23C to view these neurovascular structures as they relate to the semitransparent C7 vertebra and ribs.

Clinical Relevance: Nerves traversing this well-muscled region run the risk of entrapment and irritation, producing neck, shoulder, and upper thoracic pain.

Note the significant autonomic structures living level with BL 11, apparent in Figure 7-23C, including the cervicothoracic (stellate) sympathetic ganglion, vagus nerve, and nervi vasorum of local major vessels. While Figure 7-24 indicates that abundant muscle tissue separates BL 11 from this neurovasculature, somatoautonomic reflexes reverberate from afferents that supply this point and cervicothoracic spinal cord segments. Acupuncture stimulation that affects the stellate ganglion neuromodulates sympathetic function, affecting associated autonomic disorders such Raynaud's phenomenon, hyperhidrosis (extreme sweating) of the hands, complex regional pain syndrome type 1 (reflex sympathetic dystrophy), and hot flashes/nigh awakenings experienced by menopausal women and some breast cancer survivors. Acupuncture and related techniques performed in this region may aid recovery of complications from stellate ganglion block including Horner's syndrome, dysphagia, and local pain, though ventral cervical points allow more direct access to the sympathetic ganglia in the neck.

BL 11 has historically been called an "influential" point for bone. If BL 11 does, in fact, support bone mass, growth, and repair, it is likely due to the influence of BL 11 on sympathetic nervous system activity in terms of modulating (reducing) hyperactivity in this limb of the autonomic nervous system. Research demonstrates that increased sympathetic activity reduces bone formation and mass. It also likely increases postmenopausal bone loss in women.[2]

Afferent input from BL points on the back travels through the dorsal rami of the spinal nerves to reach the spinal cord. Abundant interneuronal connections between somatic and autonomic pathways produce reverberating effects, including somatovisceral and somatosomatic reflexes. Organs or body regions influenced by BL points depend on their location within the trunk. The classical Shu-Mu subsystem of points pairs twelve BL points with twelve discrete organs or structures. However, the neuroanatomical reality does not justify this one-to-one assignment. That is, nerves from internal organs diverge to join the spinal cord over several segments. What the point-pairing system does provide is a starting point from which an acupuncturist can begin examining and palpating for tenderness, tissue, or texture changes that may indicate either abnormalities in the local musculature, reflexes from dysfunctional viscera, or both. Viewing the organ linkages as regions instead of specific levels, one can associate BL 11 through BL 15 with the cardiopulmonary system; BL 17 through BL 19 to hepatobiliary activities, and BL 20 and BL 21 to digestion in the cranial abdomen. Coursing caudally, BL 22 and BL 23 correspond to the adrenal gland and kidney while BL 25-BL 27 connect with intestinal activity. BL 28 has been assigned to the urinary bladder, but treating bladder dysfunction may call for stimulation of several dorsal sacral spinal nerves to neuromodulate micturition and bladder sensation.

Vessels

- **First posterior intercostal artery:** Arises from the supreme intercostal artery, a branch of the costocervical artery of the subclavian artery. Provides branches that supply the dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and the skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and the parietal pleura.
- **First posterior intercostal vein:** Posterior intercostal veins anastomose with the anterior intercostal veins, which are tributaries of the internal thoracic veins. The 1st through the 3rd

Figure 7-24. Cross-sections supply information important for trigger point therapists to know regarding the depth and direction of needling necessary to deactivate key sites. As indicated here, a needle entering BL 11 first encounters the robust trapezius, followed by the rhomboids and erector spinae column.

intercostal veins either empty into the brachiocephalic vein or superior vena cava. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Large vessels, exhibiting diameters greater than 1 mm, travel caudal to the thoracic vertebrae and pierce the superficial fascia to supply cutaneous levels.[3] Certain vessels accompany a nerve and perforate slips of semispinalis muscle over along one or more vertebral segments. Other vessels inhabit deep vertebral regions and reside near the rotator muscles. Obviously, tension in the paraspinal muscle bundles impacts not only nerves but also partner vessels by reducing oxygen perfusion and eliminating metabolic waste products. This then precipitates further myofascial trigger point generation.

The azygous and vertebral venous systems comprise part of the venous network comprising the GV channel. In that most of the intercostal veins drain into the azygous system, the BL and GV channels exhibit similarities and connections in their vascular and neural compositions.

Indications and Potential Point Combinations

- **Fever:** BL 11, LI4, LI 11, GV 14, ST 36
- **Headache:** BL 11 if tender. Other local tender myofascial trigger points, as well as BL 10, GV 20, LI 4.
- **Shoulder pain:** BL 11 as a local tender trigger point or others in the vicinity; check SI 11, SI 12. For joint pain, add LI 15, TH 14.
- **Paresthesias of thoracic limb:** BL 11, GV 14, LI 4, other pertinent points related neuroanatomically.
- **Neck pain:** BL 11, local trigger points, distal point such as LI 4 or SI 3.

Evidence-Based Applications

- Prophylactic use of bilateral noninvasive acuplaster on BL 10, BL 11, and GB 34 significantly reduces **vomiting in children after strabismus correction.**[1]

BL 12

Feng Men "Wind Gate"

On the upper thorax, about 1.5 cun lateral to the caudal border of the T2 spinous process.

CAUTION: Needle carefully to avoid pneumothorax. Compare the cross section of BL 12 (Figure 7-26) with that of BL 11 (Figure 7-24). The upper lobes of the lungs have now come into play. As with BL 11, needling BL 12 poses a greater risk of causing pneumothorax in thin, poorly muscled, and/or geriatric patients when the direction of needling faces away from the midline.

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles (transversospinalis, longissimus thoracis, and iliocostalis thoracis muscles):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.
- **Splenius cervicis muscle:** Bilateral action extends the neck and head; unilateral action laterally flexes and rotates the head and neck to the ipsilateral side.

Clinical Relevance: Trigger points lurking beneath BL 12 may be housed in the trapezius, rhomboid major, splenius cervicis, and erector spinae group, as becomes apparent in the cross section seen in Figure 7-26. Referred pain from these sites travels to the neck and shoulder. Note the differences in texture between the superficial and deep layers of muscle beneath BL 12. This can translate into changes in resistance encountered by a needle, as perceived by the acupuncturist, thereby announcing the muscles reached with the needle tip.

Acupuncture, massage, and laser therapy address restrictions in this well-muscled region to improve circulation, reduce pain, and counter nerve irritation and entrapment.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **C5, C8, T1, T2 and T3 spinal nerves:** Dorsal rami innervate skin, bones, joints, muscles of the back. Ventral rami form intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **C5, C6 dorsal primary rami:** Supplies the splenius cervicis muscle.
- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5

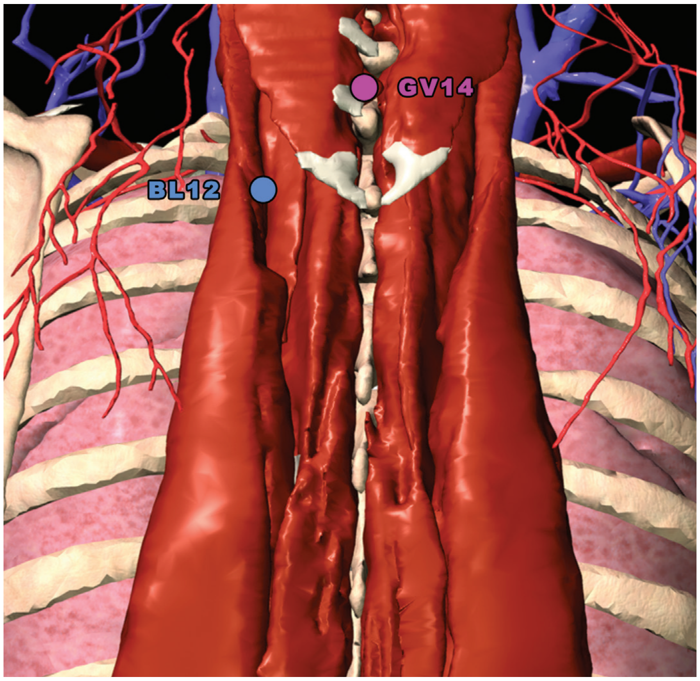

Figure 7-25A. BL 12, "Wind Gate" refers to where early Chinese acupuncturists believed that wind from cold, gusty weather entered the body, causing "cold wind invasion". We now call this "early viral illness." Neuroanatomically, BL 12 neuromodulates cranial thoracic spinal segments that send sympathetic nerve fibers to the bronchi, trachea, lungs, and the upper respiratory airways. BL 12 has also been called the influential point for wind and the trachea. Evidence suggests that acupuncture at BL 12, BL 13, and GV 14 inhibited airway remodeling in a rodent model of asthma, possibly related to the inhibition of T-type calcium channel protein in airway smooth muscle.[6]

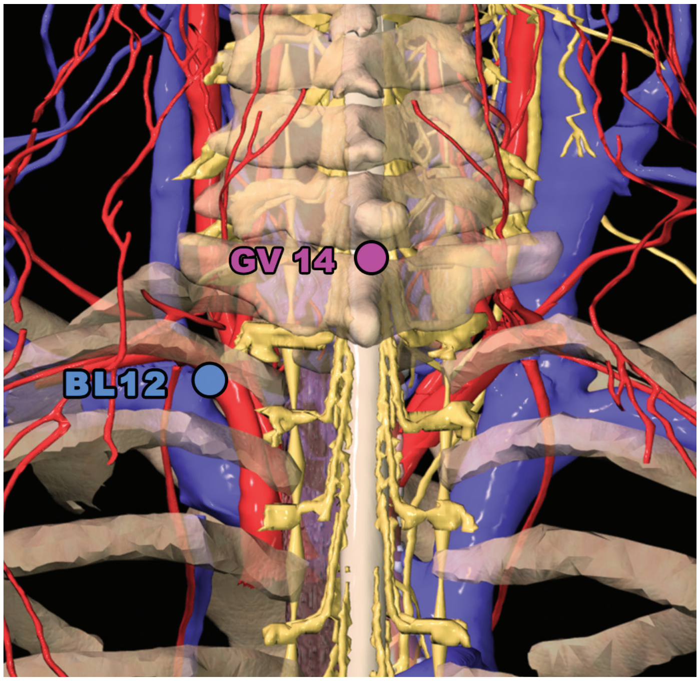

Figure 7-25B. Although the lungs span many vertebral segments, their sympathetic and sensory nerves arise from the nearby sympathetic chain ganglia and cranial spinal cord segments (shown here) near the key points for respiratory conditions: BL 12, BL 13, and GV 14.

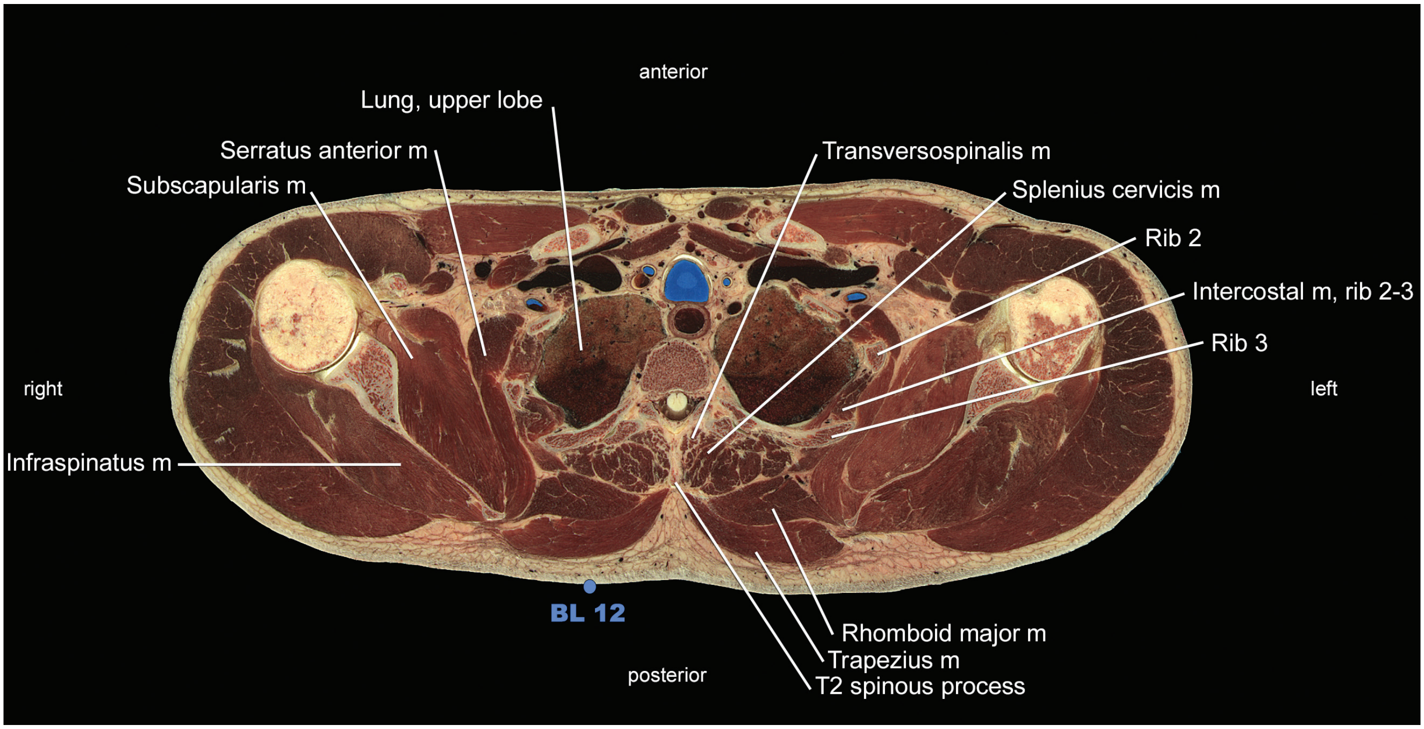

Figure 7-26. Anatomical structures closely affiliated with BL 12 figure prominently in this cross section, namely the trachea (in blue), lungs, and myofascia of the upper back.

and often receives contribution from C4. May provide fibers to the levator scapulae muscle.

Clinical Relevance: Nerves traversing this well-muscled region run the risk of entrapment and irritation. In addition, reflexes between the BL points on the back and the spinal cord yield pathways through which to affect internal organ function. That is, afferent input from BL points on the back travels through the dorsal rami of the spinal nerves to reach the spinal cord. Abundant interneuronal connections between somatic and autonomic pathways produce reverberating effects, including somatovisceral and somatosomatic reflexes. Organs or body regions influenced by BL points depend on their location within the trunk. The classical Shu-Mu subsystem of points pairs twelve BL points with twelve discrete organs or structures. However, the neuroanatomical reality does not justify this one-to-one assignment. That is, nerves from internal organs diverge to join the spinal cord over several segments. What the point-pairing system does provide is a starting point from which an acupuncturist can begin examining and palpating for tenderness, tissue, or texture changes that may indicate either abnormalities in the local musculature, reflexes from dysfunctional viscera, or both. Viewing the organ linkages as regions instead of specific levels, one can associate BL 11 through BL 15 with the cardiopulmonary system; BL 17 through BL 19 to hepatobiliary activities, and BL 20 and BL 21 to digestion in the cranial abdomen. Coursing caudally, BL 22 and BL 23 correspond to the adrenal gland and kidney while BL 25-BL 27 connect with intestinal activity. BL 28 has been assigned to the urinary bladder, but treating bladder dysfunction may call for stimulation of several dorsal sacral spinal nerves to neuromodulate micturition and bladder sensation.

Vessels

- **Second posterior intercostal artery:** Arises from the supreme intercostal artery, a branch of the costocervical artery of the subclavian artery. Provides branches that supply the dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and the skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and the parietal pleura.
- **Second posterior intercostal vein:** Posterior intercostal veins anastomose with the anterior intercostal veins, which are tributaries of the internal thoracic veins. The 1st through the 3rd intercostal veins either empty into the brachiocephalic vein or superior vena cava. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Large vessels, exhibiting diameters greater than 1 mm, travel caudal to the thoracic vertebrae and pierce the superficial fascia to supply cutaneous levels.[1] Certain vessels accompany a nerve and perforate slips of semispinalis muscle over along one or more vertebral segments. Other vessels inhabit deep vertebral regions and reside near the rotator muscles. Obviously, tension in the paraspinal muscle bundles impacts not only nerves but also partner vessels by reducing oxygen perfusion and eliminating metabolic waste products. This then precipitates further myofascial trigger point generation.

Indications and Potential Point Combinations

- **Early viral illness, with fever, headache:** BL 12, GV 14, BL 10, ST 36.
- **Respiratory problems:** dyspnea, bronchitis, and asthma: BL 12, BL 13, LU 1, LI 4, ST 36. Consider adding Dingchuan (0.5 cun on either side of GV 14), BL 20, BL 23.[2]
- **Back pain, shoulder pain:** BL 12 if tender, plus trigger points and spinal segmental BL points. Consider warming and myofascial release in the areas of BL 12, BL 13, SI 13, SI 12, and associated trigger points and taut bands.[3]
- **Urticaria:** BL 12, LI 11, LU 7, SP 10, ST 36.

Evidence-Based Applications

- **Allergic rhinitis:** BL 12[4] point injection
- **Allergy-related diseases (rhinitis, asthma, or eczema):** Herbal plaster applied to BL 12 and BL 13.[5]

BL 13

Fei Shu "Lung Shu"

On the thoracic vertebral region, 1.5 cun lateral to the inferior border of the T3 spinous process.

CAUTION: Needle carefully to avoid pneumothorax.[1]

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Serratus posterior superior muscle:** Elevates the upper four ribs, thereby raising the sternum and increasing the anteroposterior diameter of the thorax.
- **Erector spinae muscles (transversospinalis, longissimus thoracis, and iliocostalis thoracis muscles):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.
- **Transversospinal muscles (part of the erector spinae group):** These muscles originate from the transverse processes of vertebrae and insert on the spinous processes of the upper vertebrae. They include the semispinalis (capitis, cervicis, and thoracis), multifidus, and rotatores (cervicis, thoracis, and lumborum) muscles. All are innervated by dorsal primary rami of spinal nerves. The semispinalis arises from transverse processes of C4 to T12 vertebrae; the multifidus arises from the transverse processes of T1-T3; the rotatores arise from the transverse processes of vertebrae and insert onto the lower

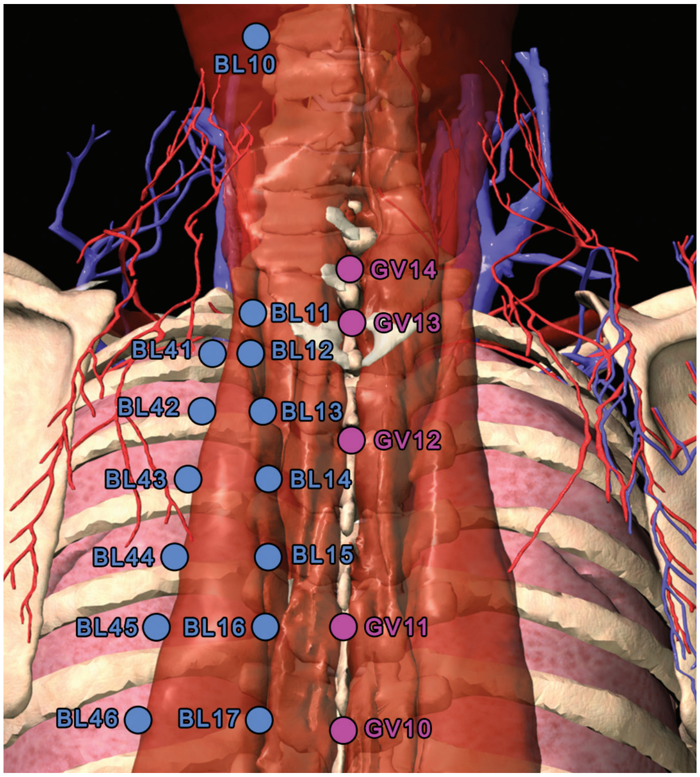

Figure 7-27A. BL 13, "Lung Transport", signifies the start of the Back Shu points on the inner BL channel. Although not all inner BL line points qualify as Back Shu, all Back Shu fall along the inner BL line in a discontinuous fashion. The diagnostic information and treatment benefits of the Back Shu points become available as a result of various viscerocutaneous, cutaneovisceral, cutaneosmuscular, and visceromuscular reflexes.[9] The layout of the Back Shu point-organ relationships expose the spinal segmental craniocaudal distribution of sympathetic (from T1 to L3) and parasympathetic spinal nuclei (S2-S4) that innervate the viscera. BL 13, "Lung Transport", derives and sends signals from and to the lungs, the most cranial member of the viscera in this system, as its name implies. Back Shu points that become tender may indicate either a viscerosomatic reflex that took hold because nociceptive impulses from the organ facilitated the recipient spinal cord segment. Alternatively, a tender Back Shu point may predominantly reflect local musculoskeletal dysfunction or a neuropathic nerve. The remainder of the examination should yield more establishing a definitive diagnosis. Note that in this image, the location of both the inner and outer BL points pertain to muscle borders rather than strict cun, or body inch, measurements, improving their correspondence to spinal nerve branching patterns as a result.

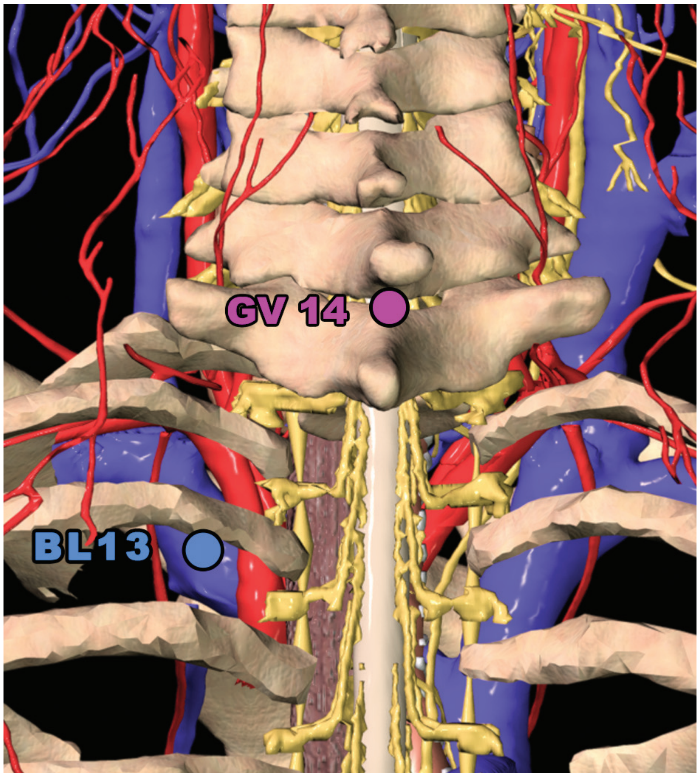

Figure 7-27B. Note the chain of sympathetic ganglia traveling parallel to the spinal cord on the left and right sides just ventral to the head of each rib. This anatomic proximity argues for various neuromodulatory techniques that modulate sympathetic activity, such as the osteopathic manipulative approach called "rib raising" in which pressure is applied to the rib heads of a patient lying supine. This technique is frequently used for lung conditions such as pneumonia, chronic obstructive pulmonary disease (COPD), and asthma.[10] Acupuncture, like the osteopathic manipulative technique of rib raising, has the capacity to neuromodulate sympathetic function, but it lacks the mechanical attributes of mobilizing the rib cage through the direct, upward pressure of the physician's extended fingers beneath the rib heads of the supine patient. Clearly, a multiplicity of approached can combine to optimize patient wellness and recovery.

border and lateral portion of the lamina of the vertebra located above it (and only exist in the thoracic region).

The transversospinal muscles extend the head, cervical, and thoracic regions; they stabilize vertebral movements; assist with local extension and rotational movements. Rotatores may also function as proprioceptive organs.

- **Splenius cervicis muscle:** Bilateral action extends the neck and head; unilateral action laterally flexes and rotates the head and neck to the ipsilateral side.

Clinical Relevance: Trigger points lurking beneath BL 13 may be housed in the trapezius, rhomboid major, splenius cervicis, and erector spinae group, as becomes apparent in the cross section seen in Figure 7-28. Referred pain from these sites travels to the neck and shoulder. Note the differences in texture between the superficial and deep layers of muscle beneath BL 13. Care and attention paid to the ways in which the resistance to needle entry feels throughout the insertion process bestows insights into the muscle layer the tip encounters along its course.

Acupuncture, massage, and laser therapy address restrictions in this well-muscled region to improve circulation, reduce pain, and counter nerve irritation and entrapment. In addition, studies show that patients suffering from chronic mechanical neck pain exhibit alterations in the differential activation of cervical extensors such as the splenius and semispinalis muscles.[4] Neuromodulation by means of acupuncture and related techniques influence unconscious proprioceptors and increase signals sent to the central nervous system. Thus, the multiplicity of mechanisms underlying neck pain falls within the spectrum of changes induced by acupuncture, including modulation of cortical excitability, reflex-mediated responses, sympathetic activation, psychological influences, and peripheral sensitization.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **C5, T1, T2, T3 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **T2-T5 spinal nerves, ventral rami (2nd to 5th intercos tal nerves):** Innervate serratus posterior superior muscle.
- Dorsal scapular nerve (C4, C5): innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.
- **C5, C6 dorsal primary rami:** Supplies the splenius cervicis muscle.

Clinical Relevance: Nerves traversing this well-muscled region run the risk of entrapment and irritation. In addition, reflexes between the BL points on the back and the spinal cord yield pathways through which to affect internal organ function. That is, afferent input from BL points on the back travels through the dorsal rami of the spinal nerves to reach the spinal cord. Abundant interneuronal connections between somatic and autonomic pathways produce reverberating effects, including somatovisceral and somatosomatic reflexes. Organs or body regions influenced by BL points depend on their location within the trunk. The classical Shu-Mu subsystem of points pairs twelve BL points with twelve discrete organs or structures. However, the neuroanatomical reality does not justify this one-to-one assignment. That is, nerves from internal organs diverge to join the spinal cord over several segments. What the point-pairing system does provide is a starting point from which an acupuncturist can begin examining and palpating for tenderness, tissue, or texture changes that may indicate either abnormalities in the local musculature, reflexes from dysfunctional viscera, or both. Viewing the organ linkages as regions instead of specific levels, one can associate BL 11 through BL 15 with the cardiopulmonary system; BL 17 through BL 19 to hepatobiliary activities, and BL 20 and BL 21 to digestion in the cranial abdomen. Coursing caudally, BL 22 and BL 23 correspond to the adrenal gland and kidney while BL 25-BL 27 connect with intestinal activity. BL 28 has been assigned to the urinary bladder, but treating bladder dysfunction may call for stimulation of several dorsal sacral spinal nerves to neuromodulate micturition and bladder sensation.

Vessels

- **Third posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Third posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. The 1st through the 3rd intercostal veins either empty into the brachiocephalic vein or superior vena cava. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Complications caused by surgery designed to block T2 sympathetic ganglion function in cases of palmar hyperhidrosis may cause various complications, including compensatory sweating and facial anhidrosis (since the T2 postganglionic fibers affect the face in some patients).[5] In order to avoid problems caused by T2 ganglion block, surgeons may instead perform sympathicotomy or ramicotomy at T3 and T4. However, significant bleeding may result from injury to the ventral crossing intercostal veins at the third and fourth intercostal spaces on the right side. Review the location of the sympathetic ganglia at T3 in Figure 7-27B and the proximity of BL 13 to the T3 ganglion on the left.

Indications and Potential Point Combinations

- **Lung problems: cough, dyspnea, bronchitis, pneumonia, asthma,[6] and pleuritis:** BL 13, LU 1, LU 5, LI 4, ST 36, GV 14.
- **Fever:** BL 13, GV 14, LI 11, LI 4, GV 20.

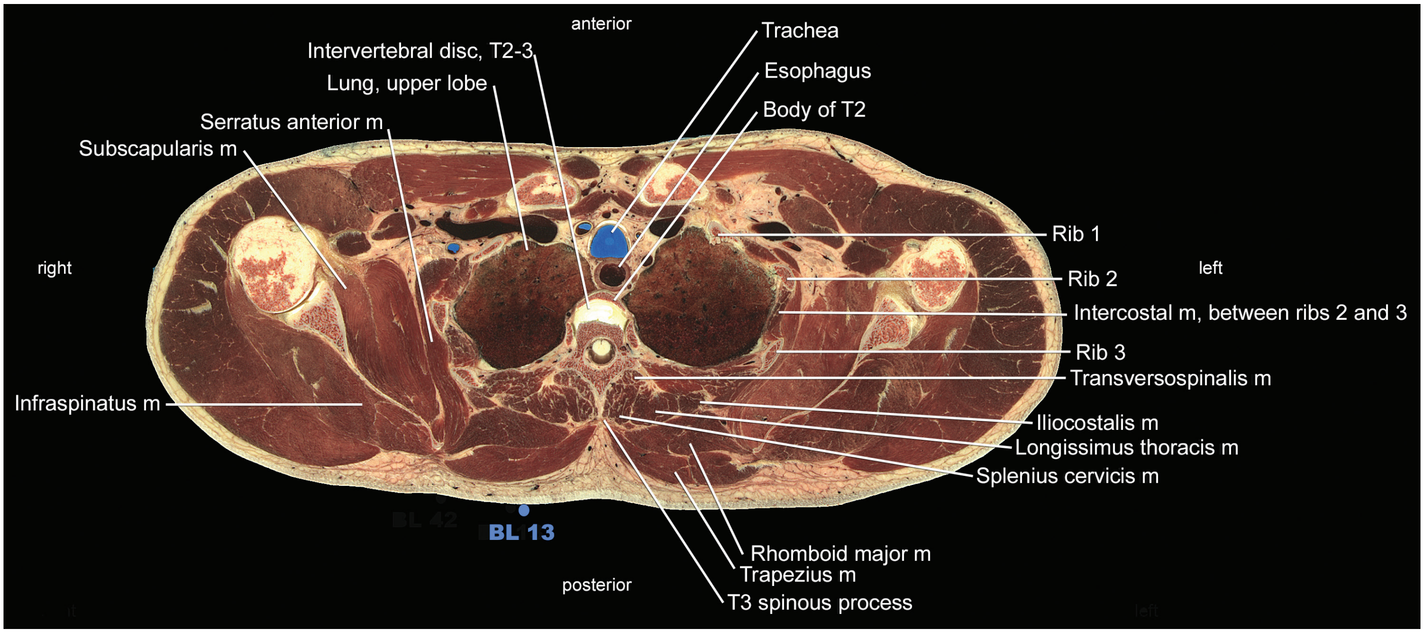

Figure 7-28. Signals "transported" from the lungs to the spinal cord, then reflexing to the body surface at "Lung Transport" (BL 13) may cause tissue, texture, and tenderness changes in this region. This happens because sympathetic neurons supplying the lungs arise from T1 to T4 communicate with nerve fibers supplying somatic tissue connected to the same segments. Although BL 13 lands at T3, nociceptive signals ascend and descend when they reach the spinal cord, causing changes at more than one level. The dermatomes associated with the lung span the T2-T4 levels, but tenderness to palpation stemming from lung issues may incite maximal discomfort at BL 13.[11]

Evidence-Based Applications

- **Bronchial asthma in children,** treated with BL 13, BL 43, Dingchuan, CV 22, and CV 17 in a Chinese study aided in preventing and treating the condition.[7]
- Herbal plaster applied to BL 13, BL 23, GV 14, CV 22, CV 17, and LU 1 in patients with **COPD** reduced frequency of episodes, improved quality of life, and increased pulmonary function in a Chinese study.[8]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[2]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[3]

BL 14

Jue Yin Shu "Fainting" or "Reverting Yin Shu"

On the thoracic vertebral region, 1.5 cun lateral to the inferior border of the T4 spinous process. Ideally, locate in the 4th intercostal space between the longissimus and iliocostalis thoracis muscles.

CAUTION: Needle carefully to avoid pneumothorax.[1] Review the relationship between BL 14 and the lung in Figure 7-29A.

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles:** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.
- **Transversospinal muscles (part of the erector spinae group):** These muscles take their origin from the transverse processes of vertebrae and insert on the spinous processes of the upper vertebrae. They include the semispinalis (capitis, cervicis, and thoracis), multifidus, and rotatores (cervicis, thoracis, and lumborum) muscles. All are innervated by dorsal primary rami of spinal nerves. The semispinalis arises from transverse processes of C4 to T12 vertebrae; the multifidus arises from the transverse processes of T1-T3; the rotatores arise from the transverse processes of vertebrae and insert onto the lower border and lateral portion of the lamina of the vertebra located above it (and only exist in the thoracic region).

The transversospinal muscles extend the head, cervical, and thoracic regions; they stabilize vertebral movements; assist with local extension and rotational movements. Rotatores may also function as proprioceptive organs.

Clinical Relevance: Trigger points lurking beneath BL 14 may be housed in the trapezius, rhomboid major, and erector spinae group, as becomes apparent in the cross section seen in Figure 7-30. Referred pain from trigger points in the deep paraspinal muscles such as the multifidi and rotatores refer pain strongly to the local region. At BL 14, pain can span the distance from the spine to the medial border of the scapula. Iliocostalis thoracis trigger points refer to the groove between the scapula and spine. They may also send pain to the chest at about the same horizontal plane as the trigger point. Trigger points in the midthoracic levels of the iliocostalis thoracis that refer to the parasternal region can cause the patient to complain of chest pain and worry about cardiac dysfunction.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T1, T2, T3, and T4 spinal nerves:** Dorsal ramus innervates skin,

Figure 7-29A. Needles entering BL 14, like the other BL points on the thorax, risk penetrating the lung,as indicated here. Note, too, that BL 14 has landed in the 4th intercostal space. This causes it to sit more cranial than the traditional location specifies. Disparities such as this highlight the reality that points placed on two-dimensional images show where to begin palpating. Features that determine ultimate point placement include locating a depression in the tissue, finding tenderness to palpation, detecting a taut band or trigger point, or isolating other expressions of tissue dysfunction and neuronal misfiring. One also needs to avoid areas of infection, masses, and cancer.

bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: Nerves traversing this well-muscled region run the risk of entrapment and irritation. In addition, reflexes between the BL points on the back and the spinal cord yield pathways through which to affect internal organ function. That is, afferent input from BL points on the back travels through the dorsal rami of the spinal nerves to reach the spinal cord. Abundant interneuronal connections between somatic and autonomic pathways produce reverberating effects, including somatovisceral and somatosomatic reflexes. Organs or body regions influenced by BL points depend on their location within the trunk. The classical Shu-Mu subsystem of points pairs twelve BL points with twelve discrete organs or structures. However, the neuroanatomical reality does not justify this one-to-one assignment. That is, nerves from internal organs diverge to join the spinal cord over several segments. What the point-pairing system does provide is a starting point from which an acupuncturist can begin examining and palpating for tenderness, tissue, or texture changes that may indicate either abnormalities in the local musculature, reflexes from dysfunctional viscera, or both. Viewing the organ linkages as regions instead of specific levels, one can associate BL 11 through BL 15 with the cardiopulmonary system; BL 17 through BL 19 to hepatobiliary activities, and BL 20 and BL 21 to digestion in the cranial abdomen. Coursing caudally, BL 22 and BL 23 correspond to the adrenal gland and kidney while BL 25-BL 27 connect with intestinal activity. BL 28 has been assigned to the urinary bladder, but treating bladder dysfunction may call for stimulation of several dorsal sacral spinal nerves to neuromodulate micturition and bladder sensation.

Vessels

- **Fourth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Fourth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Complications caused by surgery designed to block T2 sympathetic ganglion function in cases of palmar hyperhidrosis may cause various complications, including compensatory sweating and facial anhidrosis (since the T2 postganglionic fibers affect the face in some patients).[4] In order to avoid problems caused by T2 ganglion block, surgeons may opt for sympathicotomy or ramicotomy at T3 and T4. However, significant bleeding may result from injury to the ventral crossing intercostal veins at the third and fourth intercostal spaces on the right side. Review the location of the sympathetic ganglia at T4 in Figure 7-29B and the proximity of BL 14 to the T4 ganglia.

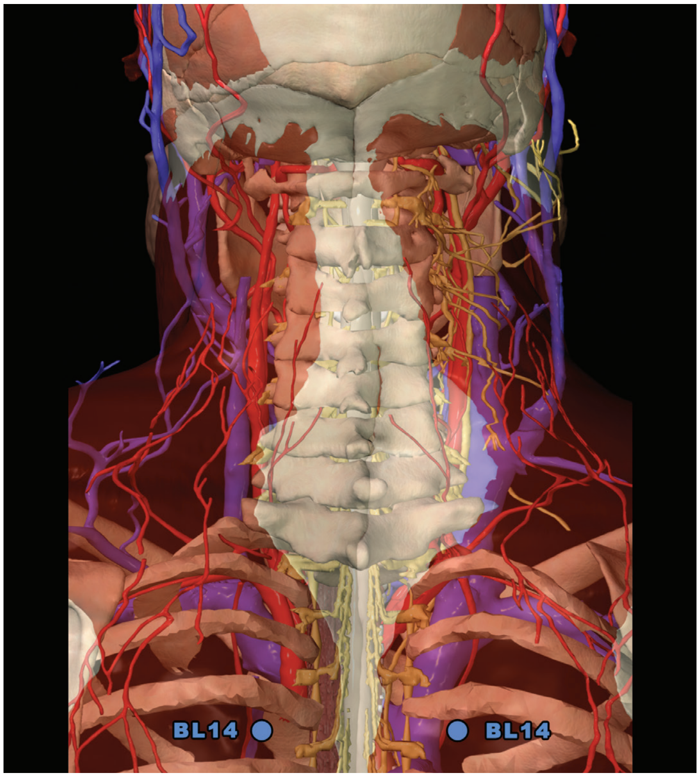

Figure 7-29B. This image is designed to promote "3D thinking". That is, given the prevalence of trigger point pathology in this region, acupuncturists may grow accustomed to focusing on myofascial dysfunction when examining and needling the upper thorax. Reminding oneself of the sympathetic chain ganglia, spinal nerves, and vascular elements beneath the musculature expands one's awareness of the physiologic activities responsible for reducing pain as well as the somatovisceral changes in cardiopulmonary function that needling may induce.

Indications and Potential Point Combinations

- **Tachycardia, myocarditis, pericarditis, angina pectoris, cough from arrhythmia, chest pressure and pain:** After instituting proper medical interventions and monitoring as necessary, consider BL 14, BL 15, PC 1, PC 6, ST 36, CV 17.
- **Agitation, anxiety:** BL 14, HT 3, HT 7, PC 7.
- **Intercostal pain:** If at this level, consider BL 14, BL 43, local trigger points.

Evidence-Based Applications

- Acupuncture at BL 14 and PC 6 caused bidirectional **regulation of cardiac sympathetic and vagal nerve activities** in a cardioprotective fashion.[2]
- Massage at BL 14 and BL 15, consisting of "palm-pushing", "palm-rubbing" and "thumb-poking" for 15 minutes every other day relieved symptoms of angina pectoris in patients with coronary artery disease.[3]

Figure 7-29C. It is often helpful to view points in the context of not only shared channels but also overlapping dermatomes. Note the way in which GB 22 and GB 23 share the 4th intercostal space with BL 14. Also, view the ventral lung fields behind the caudal sternum where the heart and pericardium peek through the 5th intercostal space. Finally, find CV 17 on the ventral midline. While not all Back Shu and Front Mu points line up along the same intercostal spaces, seeing BL 14, CV 17, and the pericardium related in this way is visually and neuroanatomically satisfying. The sympathetic neurons supplying the pericardium originate from T1 to T5.[5] The name "Jue Yin Shu" for BL 14 links its status as a Back Shu point for the pericardium to the topographical channel name for PC, "Jue Yin".

BL 15

Xin Shu "Heart Shu"

On the thoracic vertebral region, about 1.5 cun lateral to the inferior border of the T5 spinous process. Locate in the 5th intercostal space.

CAUTION: Needle carefully to avoid pneumothorax, as illustrated in Figure 7-31.

Muscles

- **Trapezius muscle:** The musculotendinous part provides added resistance to needle insertion. Caudal, or inferior, fibers depress the scapula and lower the shoulder.
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles:** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.
- **Transversospinal muscles (part of the erector spinae group):** These muscles originate from the transverse processes of vertebrae and insert on the spinous processes of the upper vertebrae. They include the semispinalis (capitis, cervicis, and thoracis), multifidus, and rotatores (cervicis, thoracis, and lumborum) muscles. All are innervated by dorsal primary rami of spinal nerves. The semispinalis arises from transverse processes of C4 to T12 vertebrae; the multifidus arises from the transverse processes of T1-T3; the rotatores arise from the transverse processes of vertebrae and insert onto the lower border and lateral portion of the lamina of the vertebra located above it (and only exist in the thoracic region).

The transversospinal muscles extend the head, cervical, and thoracic regions; they stabilize vertebral movements; assist with local extension and rotational movements. Rotatores may also function as proprioceptive organs.

Clinical Relevance: Trigger points near BL 15 occur in the trapezius, rhomboid major, and erector spinae group, as seen in Figure 7-32. Referred pain from trigger points in the deep paraspinal muscles such as the multifidi and rotatores refer pain strongly locally. This can include the site in and around BL 15, shown in Figure 7-31. Iliocostalis thoracis trigger points refer to the groove between the scapula and spine. They may also send pain to the chest at about the same horizontal plane as the trigger point. Trigger points in the midthoracic levels of the iliocostalis thoracis that refer to the parasternal region can cause the patient to complain of chest pain and worry about cardiac dysfunction.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T2-T5 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

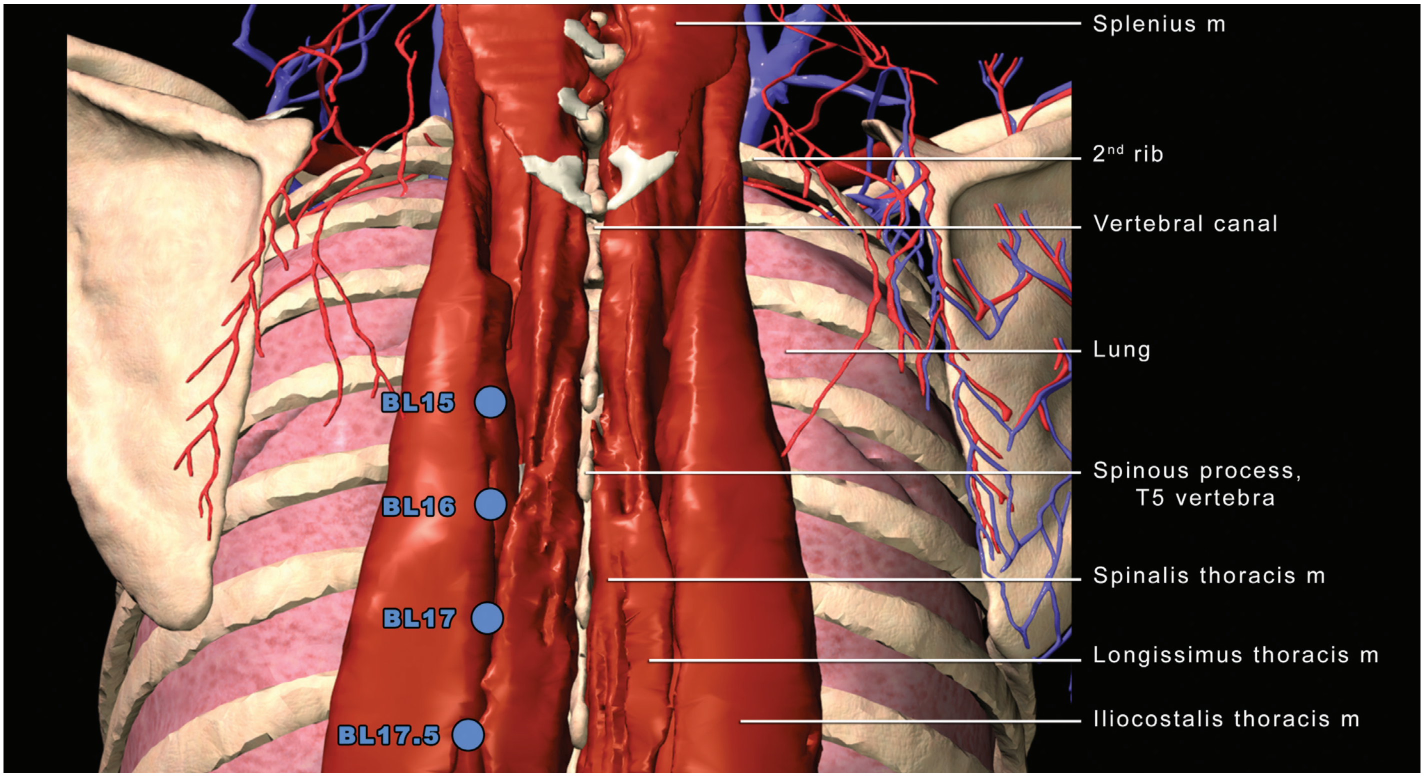

Figure 7-31. Like the other points on the inner BL line, one finds BL 15 in the groove between the longissimus thoracic and iliocostalis thoracic muscles. The dorsal primary ramus of the spinal nerves divides into medial and lateral branches deep to the border of these two muscles, immediately lateral to the articular processes of each vertebra. The medial branch surfaces close to the spinous process (associated with the GV line) while the lateral branch covers the territory of the BL channel. However, much overlap exists in the neurovascular jurisdictions of the BL and GV trajectories.

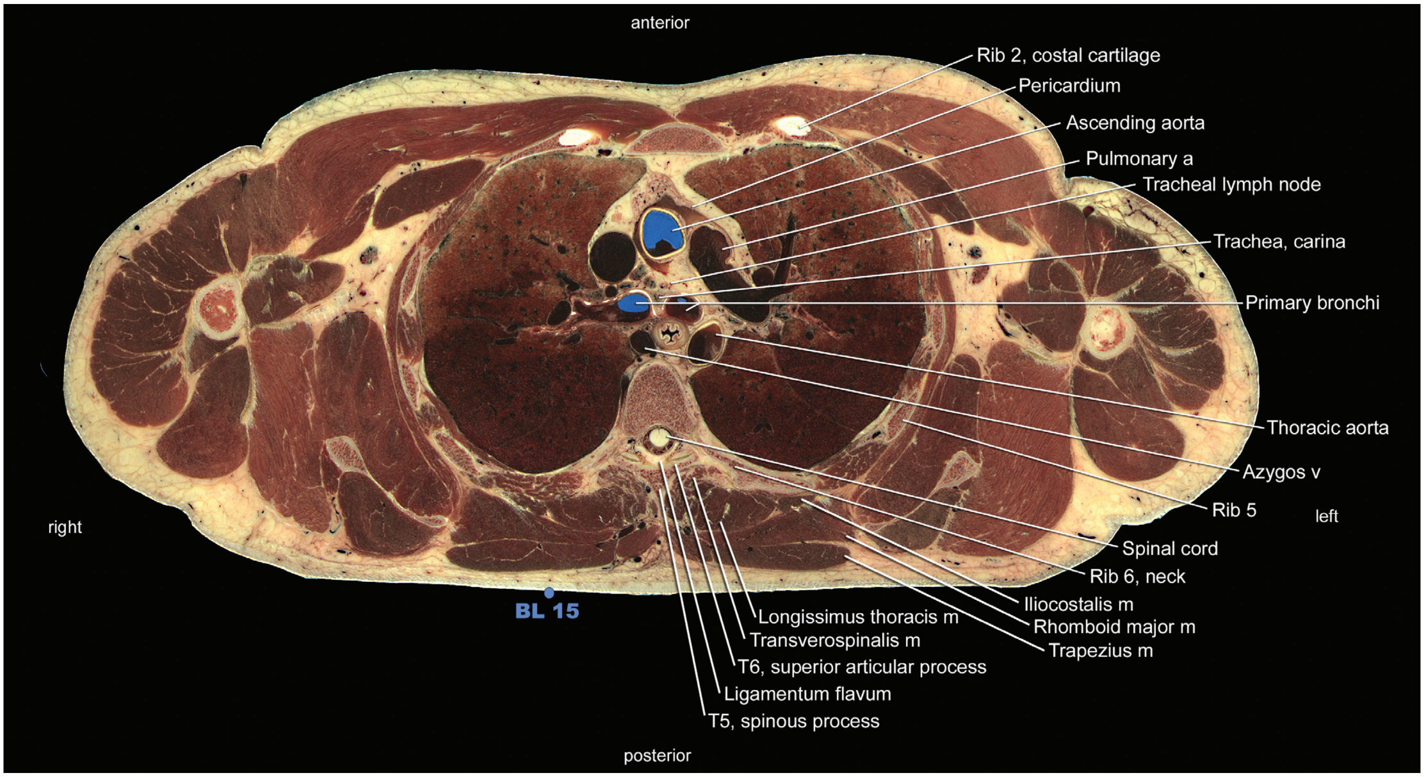

Figure 7-32. BL 15, "Heart Shu", may display tenderness to palpation in cardiac patients, as BL 15 resides in the T5 dermatome and the heart receives its sympathetic supply from T1-T5.[7] Despite the association of BL 15 with the heart, PC 6 provides a decidedly stronger anti-arrhythmic effect, perhaps due to the latter site's linkage to the rostral vetntrolateral medulla (RVLM) rather than to the cranial thoracic spinal cord segments. In this case, a direct connection to the brainstem outweighs somatovisceral reverberations through the paraspinal sympathetic chain and ganglia. Trace the pathway from BL 15 to the heart and back to the back in this cross section to appreciate the course the nerve signals take during acupuncture.

- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. In addition, reflexes between the BL points on the back and the spinal cord yield pathways through which to affect internal organ function. That is, afferent input from BL points on the back travels through the dorsal rami of the spinal nerves to reach the spinal cord. Abundant interneuronal connections between somatic and autonomic pathways produce reverberating effects, including somatovisceral and somatosomatic reflexes. Organs or body regions influenced by BL points depend on their location within the trunk. The classical Shu-Mu subsystem of points pairs twelve BL points with twelve discrete organs or structures. However, the neuroanatomical reality does not justify this one-to-one assignment. That is, nerves from internal organs diverge to join the spinal cord over several segments. What the point-pairing system does provide is a starting point from which an acupuncturist can begin examining and palpating for tenderness, tissue, or texture changes that may indicate either abnormalities in the local musculature, reflexes from dysfunctional viscera, or both. Viewing the organ linkages as regions instead of specific levels, one can associate BL 11 through BL 15 with the cardiopulmonary system; BL 17 through BL 19 to hepatobiliary activities, and BL 20 and BL 21 to digestion in the cranial abdomen. Coursing caudally, BL 22 and BL 23 correspond to the adrenal gland and kidney while BL 25-BL 27 connect with intestinal activity. BL 28 has been assigned to the urinary bladder, but treating bladder dysfunction may call for stimulation of several dorsal sacral spinal nerves to neuromodulate micturition and bladder sensation.

Vessels

- **Fifth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Fifth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Given that the 5th intercostal artery and vein supply structures associated with the spine and spinal cord, improving blood flow by neuromodulating BL points on the back gives this region a better chance to heal in the event of disabling spine and spinal cord injury.

Indications and Potential Point Combinations

- **Heart problems such as atrial fibrillation,[6] angina pectoris, and tachycardia:** After stabilizing and instituting appropriate monitoring and conventional treatment measures, consider BL 15, CV 14, HT 2, HT 3, PC 6, ST 36.Trigger points in this region (T5, T6) can produce referred pain patterns that extend to the shoulder and the chest wall. When left-sided, the pain caused by these trigger points can mimic cardiac angina.[1]

- **Intercostal neuralgia:** Isolate involved rib spaces, tender zones, and restricted intercostals muscles; needle locally. Add BL (inner and outer line) for involved segments. Consider BL 15 for midthoracic intercostals neuralgia, especially if worsened by anxiety.
- **Tension in the back:** BL 15 if tender, other local points along the inner and outer BL line.

Evidence-Based Applications

- Acupuncture at LU 9, ST 36, ST 40, SP 1, SI 3, BL 15, LR 3, CV 12, and CV 14 induced long-lasting reductions in attacks of primary **Raynaud's syndrome**, demonstrated effectiveness comparable to nifedipine, and did so without adverse effects.[2]
- Acupuncture at ST 36, BL 15, BL 20, HT 5, and PC 6 reduced the number of attacks per week in **angina pectoris** patients and reduced ST-segment depression during exercise, possibly indicating protection of the myocardium from ischemia.[3]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes**.[4]
- Massage at BL 14 and BL 15, consisting of "palm-pushing", "palm-rubbing" and "thumb-poking" for 15 minutes every other day relieved symptoms of angina pectoris in patients with **coronary artery disease.**[5]

BL 16

Du Shu "Governing Shu"

On the thoracic vertebral region, 1.5 cun lateral to the inferior border of the T6 spinous process. Locate in the 6th intercostal space.

CAUTION: Needle carefully to avoid pneumothorax.

Muscles

- **Trapezius muscle:** The caudal (inferior) fibers depress the scapula and lower the shoulder.
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Transversospinal muscles (part of the erector spinae group):** These muscles originate from the transverse processes of vertebrae and insert on the spinous processes of the upper vertebrae. They include the semispinalis (capitis, cervicis, and thoracis), multifidus, rotatores (cervicis, thoracis, and lumborum) muscles. All are innervated by dorsal primary rami of the spinal nerves. The semispinalis arises from transverse processes of C4 to T12 vertebrae; the multifidus arises from the transverse processes of T1-T3; the rotatores arise from the transverse processes of vertebrae and insert onto the lower border and lateral portion of the lamina of the vertebra located above it (and only exist in the thoracic region).

The transversospinal muscles extend the head, cervical, and thoracic regions; they stabilize vertebral movements; assist with local extension and rotational movements. Rotatores may also function as proprioceptive organs.

Clinical Relevance: Muscles enveloping the BL channel at T6 exhibit far less depth than more cranial levels do. (See Figure 7-33B.) Trigger points at BL 16 occur in the trapezius, rhomboid major, and erector spinae group. Referred pain from trigger points in the deep paraspinal muscles such as the multifidi and rotatores refer pain strongly locally. Iliocostalis thoracis trigger points refer to the groove between the scapula and spine. They may also send pain to the chest at about the same horizontal plane as the trigger point. Trigger points in the midthoracic levels of the iliocostalis thoracis that refer to the parasternal region could lead the patient to believe they are experiencing cardiac dysfunction.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T4-T6 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid

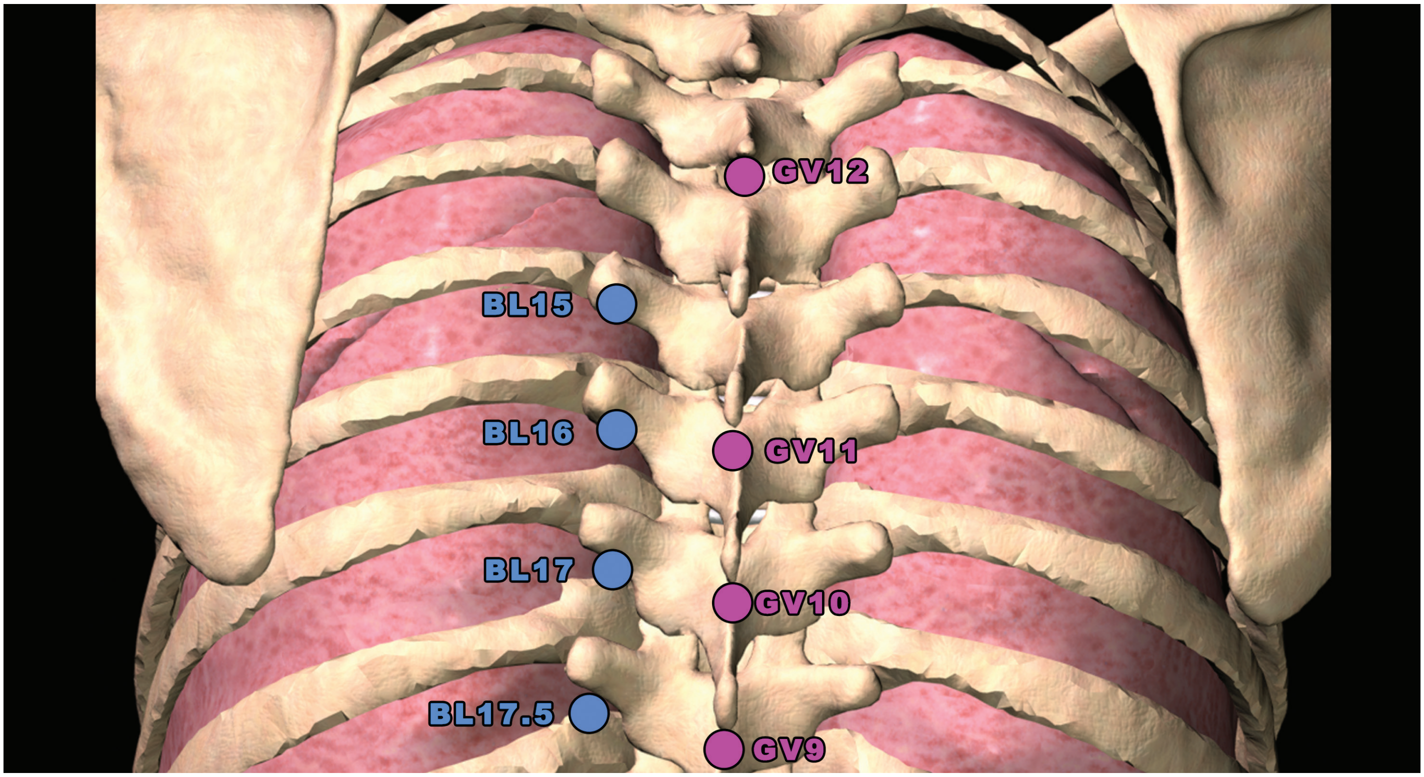

Figure 7-33A. BL 16, "Governing Shu", speaks of the relationship between the BL channel and the GV line, as illustrated here. The azygous system of veins, which includes the azygous, hemiazygous, and accessory hemiazygous veins, embody the vascular basis of the Governor Vessel, one of the eight singular vessels that some call "curious" or "extra" meridian pathways. Instead of ferrying rarified energies, the eight singular vessels consist of actual vascular conduits that are singular, or unique, in nature. The term "azygous" means "unpaired", which applies as well to the hemiazygous and accessory hemiazygous veins.

Figure 7-33B. This cross section highlights several magnificent vascular structures where they reside at center stage. As the "Governing Shu", BL 16 associates not with a viscus but with the GV, a vascular network that includes the azygous vein, shown prominently in this cross section anterior to the vertebral body. The azygous vein enters the superior vena cava at or below the level of BL 16 in most cases, at the same level of the bifurcation of the pulmonary trunk. It may join the caval venous system directly or it may empty indirectly, by means of the hemiazygous and accessory hemiazygous veins.

muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression. Furthermore, patients with back pain at this level, especially those with osteoporosis, may be suffering from a vertebral body compression fracture.[2] In these cases, high velocity, low amplitude thrusting manipulation could cause further injury, while acupuncture, careful massage, and laser therapy would more safely provide adjunctive pain relief.

Vessels

- **Sixth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Sixth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: The name for BL 16 as "Du Shu" references the Governor Vessel, manifested in part by the azygous venous system that figures prominently at this level (see Figure 7-33B), for it is at the mid-thoracic level that the hemiazygous vein joins the azygous system cranial to the vertebrae.

Indications and Potential Point Combinations

- **Chest or back pain:** Trigger points in this region (T5, T6) can produce referred pain patterns that extend to the shoulder and the chest wall. When left-sided, the pain caused by these trigger points can mimic cardiac angina.[1]

BL 17

Ge Shu "Diaphragm Shu"

On the thoracic vertebral region, approximately 1.5 cun lateral to the caudal border of the T7 spinous process.

CAUTION: Needle carefully to avoid pneumothorax.

Muscles

- **Trapezius muscle:** Inferior fibers depress the scapula and lower the shoulder.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Muscles comprising the BL channel at T7 exhibit far less depth than more cranial levels do. (See Figure 7-34.) Trigger points at BL 17 occur in the trapezius and erector spinae group. Referred pain from trigger points in the deep paraspinal muscles such as the multifidi and rotatores refer pain strongly locally. Trigger points in the midthoracic levels of the iliocostalis thoracis that refer to the parasternal region could lead the patient to believe they are experiencing cardiac dysfunction.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T4-T7 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

Vessels

- **Seventh posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Seventh posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Note the many small vessels in cross section between the aorta and T7 in Figure 7-34. These are likely branches of the adjoining hemiazygous and accessory hemiazygous veins as they travel in the direction of the azygous (or azygos) vessel. While acupuncture would not directly impact venous drainage in the posterior intercostal veins or the azygous system, pumping or compressive forces properly applied to the back would facilitate venous emptying into the caval system and

Figure 7-34. BL 17 serves a multifaceted role in Chinese medicine, said to influence the diaphragm, blood, and the esophagus. This cross section illustrates the presence of several influential blood-carrying structures sharing the plane with BL 17, including the heart, the pulmonary veins, the aorta, and the azygous venous system. The esophagus sits surrounded by these vascular conduits causing one to wonder, perhaps, how boluses of food affect venous return as they travel toward the stomach.

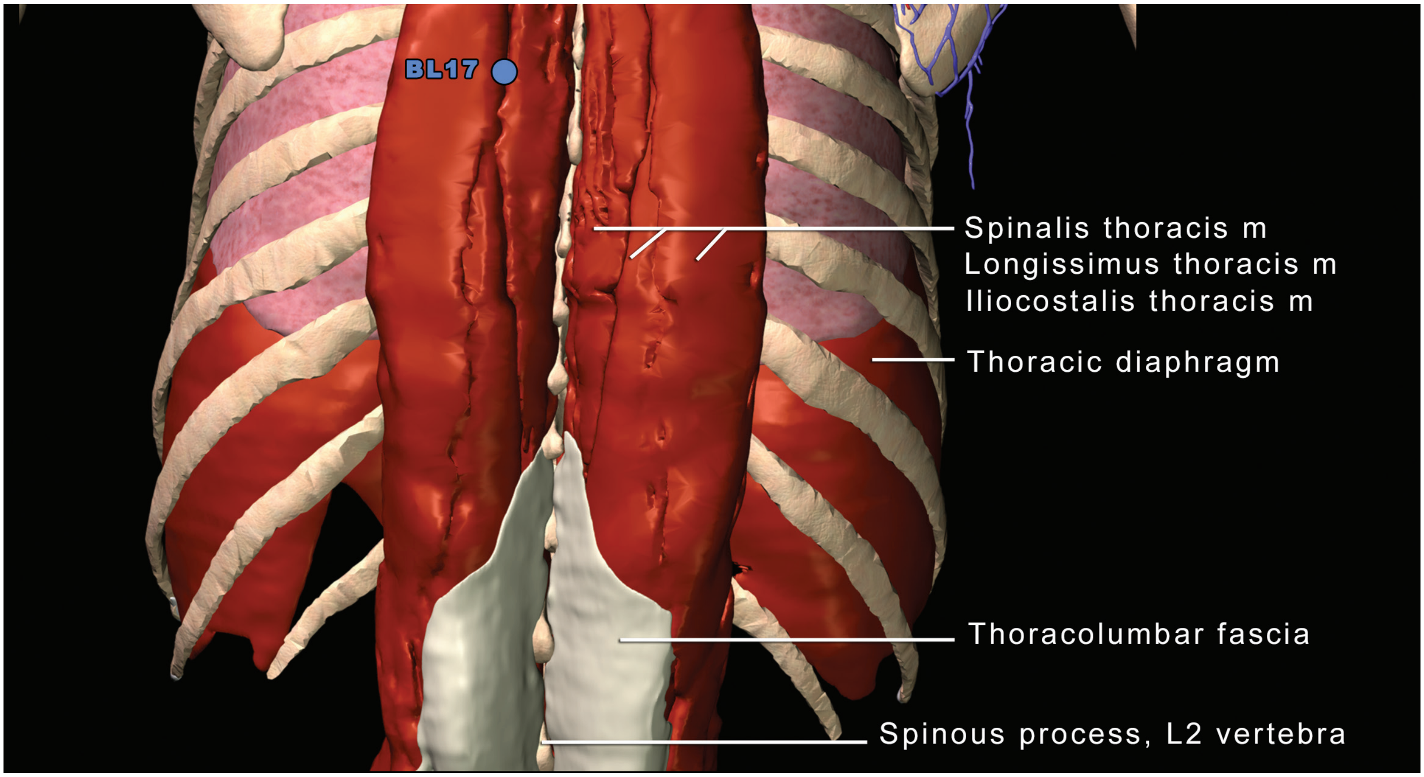

Figure 7-35. The phrenic nerve (C3-C5) supplies the sole source of motor function to the diaphragm as well as sensation to its central tendon; the lower six or seven intercostal nerves and the subcostals supply sensation to the periphery of the diaphragm. The link between BL 17 and the diaphragm may pertain to the fact that its lateral, or costal, portion attaches to the ribs 7-9.

improve elimination of metabolic waste from tense and stressed myofascia of the back.

Indications and Potential Point Combinations

- **Hiccoughs:** BL 17, CV 22, ST 36.[1]
- **Back pain:** BL 17 for local pain; add other tender trigger points; address BL and GV points just below and above vertebral segments related to the presenting somatic dysfunction.
- **Dysphagia:** BL 17, ST 36, CV 22, CV 15.
- **Vomiting or regurgitation:** BL 17, CV 12, PC 6.
- **Anemia:** BL 17, BP 10, ST 36.

Evidence-Based Applications

- Acupuncture and electroacupuncture at BL 17, BL 17.5, BL 20, BL 23, ST 36, and SP 6 effectively regulated levels of glucagon and immune factors, reduced blood coagulability, improved microcirculation, and heightened insulin sensitivity in **type-II diabetics.**[2]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus.**[3]

BL 17.5

Yi Shu; Wei Guan Xia Shu
Pancreas Shu;
"Stomach Controller Lower Shu"

Accessory Back Shu point for pancreas.

On the thoracic vertebral region, approximately 1.5 cun lateral to the caudal border of the T8 spinous process. Find between the longissimus thoracis and iliocostalis thoracis muscle columns.

CAUTION: Needle carefully to avoid pneumothorax. Refer to Figure 7-37 for the remaining contour of lung tissue visible in a cross section at this level.

Muscles

- **Trapezius muscle:** The inferior fibers depress the scapula and lower the shoulder.
- **Latissimus dorsi muscle**: Extends, adducts, medially rotates humerus.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Levator costarum muscle:** May assist with lifting the ribs during inspiration and managing spinal movement through proprioception.

Clinical Relevance: Muscles comprising the BL channel at T8 exhibit far less depth than more cranial levels do. (See Figure 7-37.) Trigger points at BL 17.5 may arise in the dwindling trapezius but are more likely to arise in the more massive longissimus thoracis. Furthermore, referred pain from trigger points in the deep paraspinal muscles such as the multifidi and rotatores refer pain strongly locally. Trigger points in the midthoracic levels of the iliocostalis thoracis that refer to the parasternal region could lead the patient to believe they are experiencing cardiac dysfunction.

As becomes evident in Figure 7-36, the cranial border of the latissimus dorsi muscle may land within the territory of BL 17.5 and as such may encounter an entering needle. When palpated at BL 17.5, patients sometimes complain of tenderness along this edge.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T4-T8 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back, including the levator costarum muscles.[2] Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

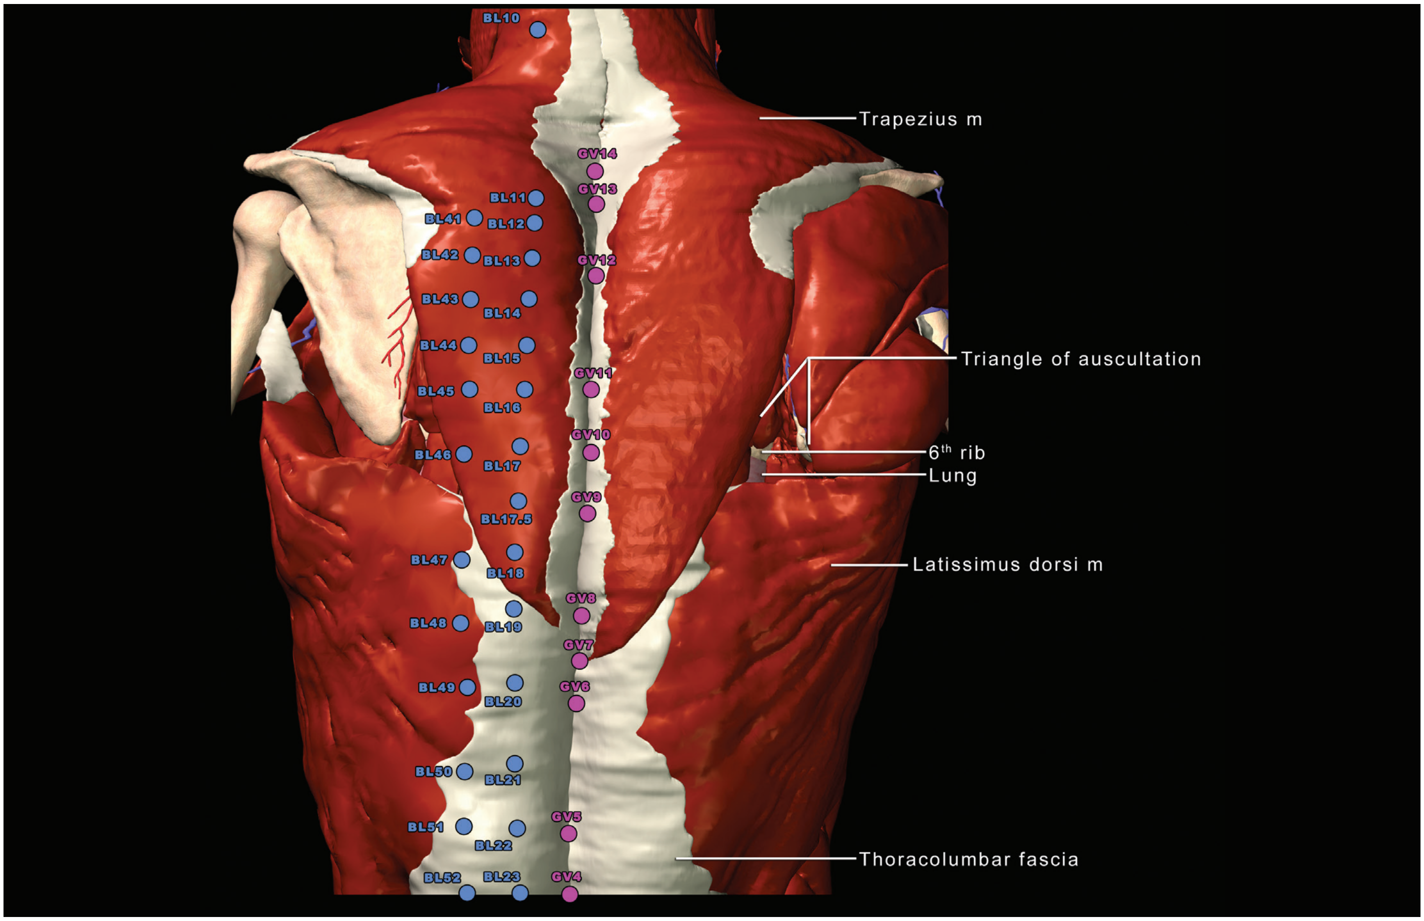

Figure 7-36. Some consider the point between BL 17 and BL 18 (BL 17.5) as the "accessory" Back Shu point for the pancreas. Point formulae for diabetic conditions usually partner BL 17.5 with BL 20, as the early acupuncturists confused the digestive functions of the pancreas with activities of the spleen.

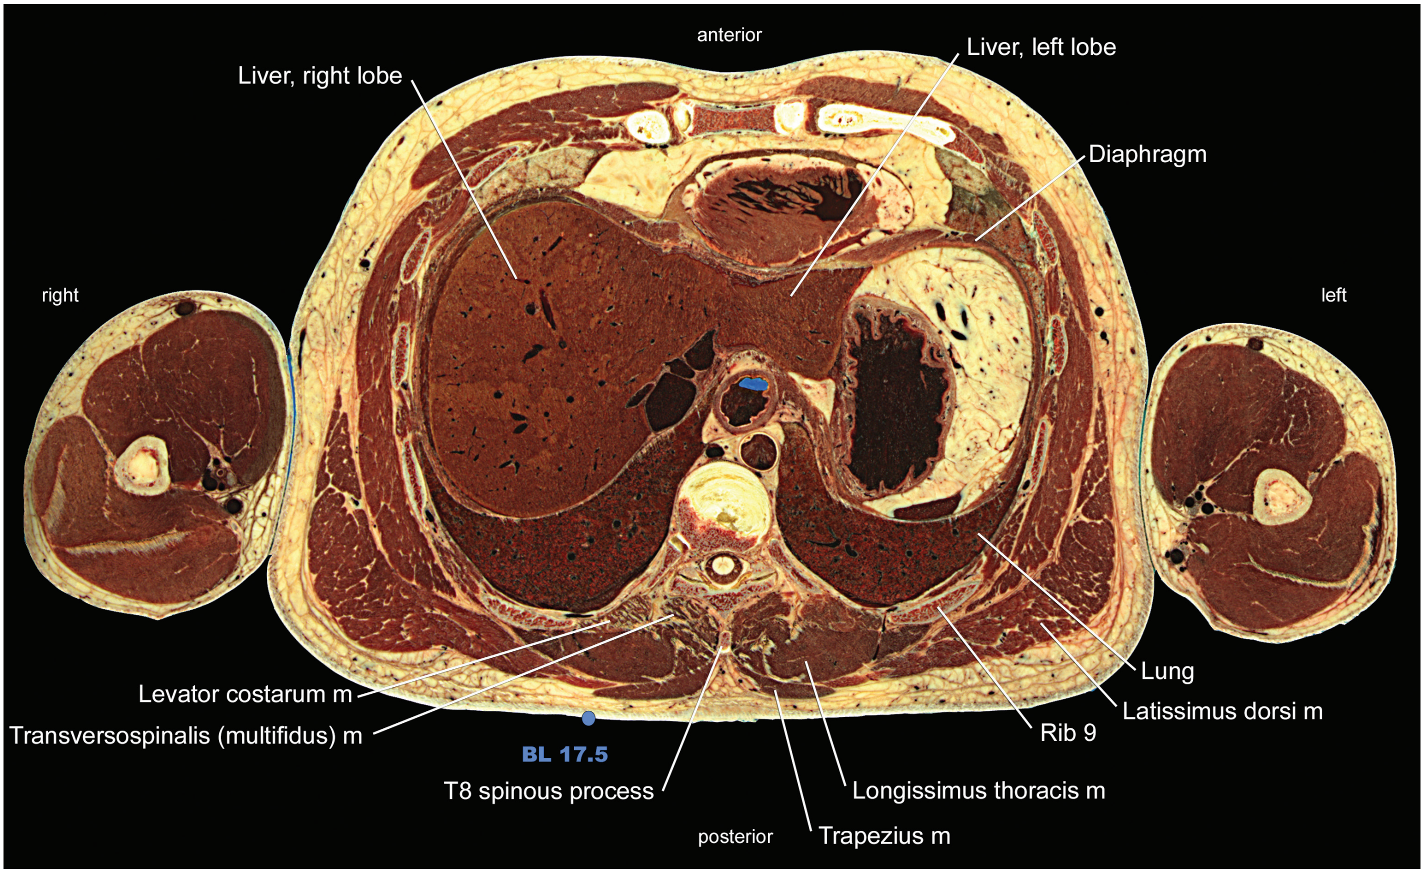

Figure 7-37. While no pancreas appears in this cross section at the level of "Pancreas Shu" (BL 17.5), the transition between the lung and liver shows up well here. The diaphragm, too, associated historically with BL 17, becomes apparent on the left ventral intra-abdominal wall.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

Vessels

- **Eighth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Eighth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Local thoracic pain:** BL 17.5 if tender. Check for diaphragmatic restriction or other compromised respiratory patterns secondary to myofascial restriction over the thoracic cage. Treat tender trigger points.
- **Pancreatitis:** BL 17.5, BL 20, CV 12, PC 6, ST 36.[3]
- **Diabetes mellitus:** BL 17.5, BL 20, SP 6, LR 13, ST 36.
- **Diabetic nephropathy:** BL 17.5, BL 20, BL 23, and ST 36.[4]

Evidence-Based Applications

- Acupuncture and electroacupuncture at BL 17, BL 17.5, BL 20, BL 23, ST 36, and SP 6 effectively regulated levels of glucagon and immune factors, reduced blood coagulability, improved microcirculation, and heightened insulin sensitivity in **type-II diabetics.**[1]
- Acupuncture at BL 17.5, BL 20, SP 6, ST 36, and other points, along with a controlled diet, assisted in lowering **postprandial blood glucose levels** more than in a control group of geriatric patients with impaired glucose tolerance.

BL 18

Gan Shu "Liver Shu"

On the thoracic vertebral region, 1.5 inferior border of the T9 spinous process. Find along the border separating the longissimus thoracis and iliocostalis thoracis muscles.

CAUTION: Needle carefully to avoid pneumothorax. View Figure 7-38A to examine where the caudal, dorsal lung fields fall in relation to the inner and outer BL channel points. Note, however, that these are unexpanded lungs.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: The longissimus thoracis muscle beneath BL 18 begins to build in bulk. (See Figure 7-39.) More muscle tissue between a point and underlying organs translates to

Figure 7-38A. The Back Shu points divide roughly into three groups: cranial thoracic, thoracolumbar, and lumbosacral, corresponding to the organs residing in the upper, middle, and lower "heaters" in Chinese medicine. The heaters correspond to organ activities in the thorax, cranial abdomen, and caudal abdomen/pelvis.

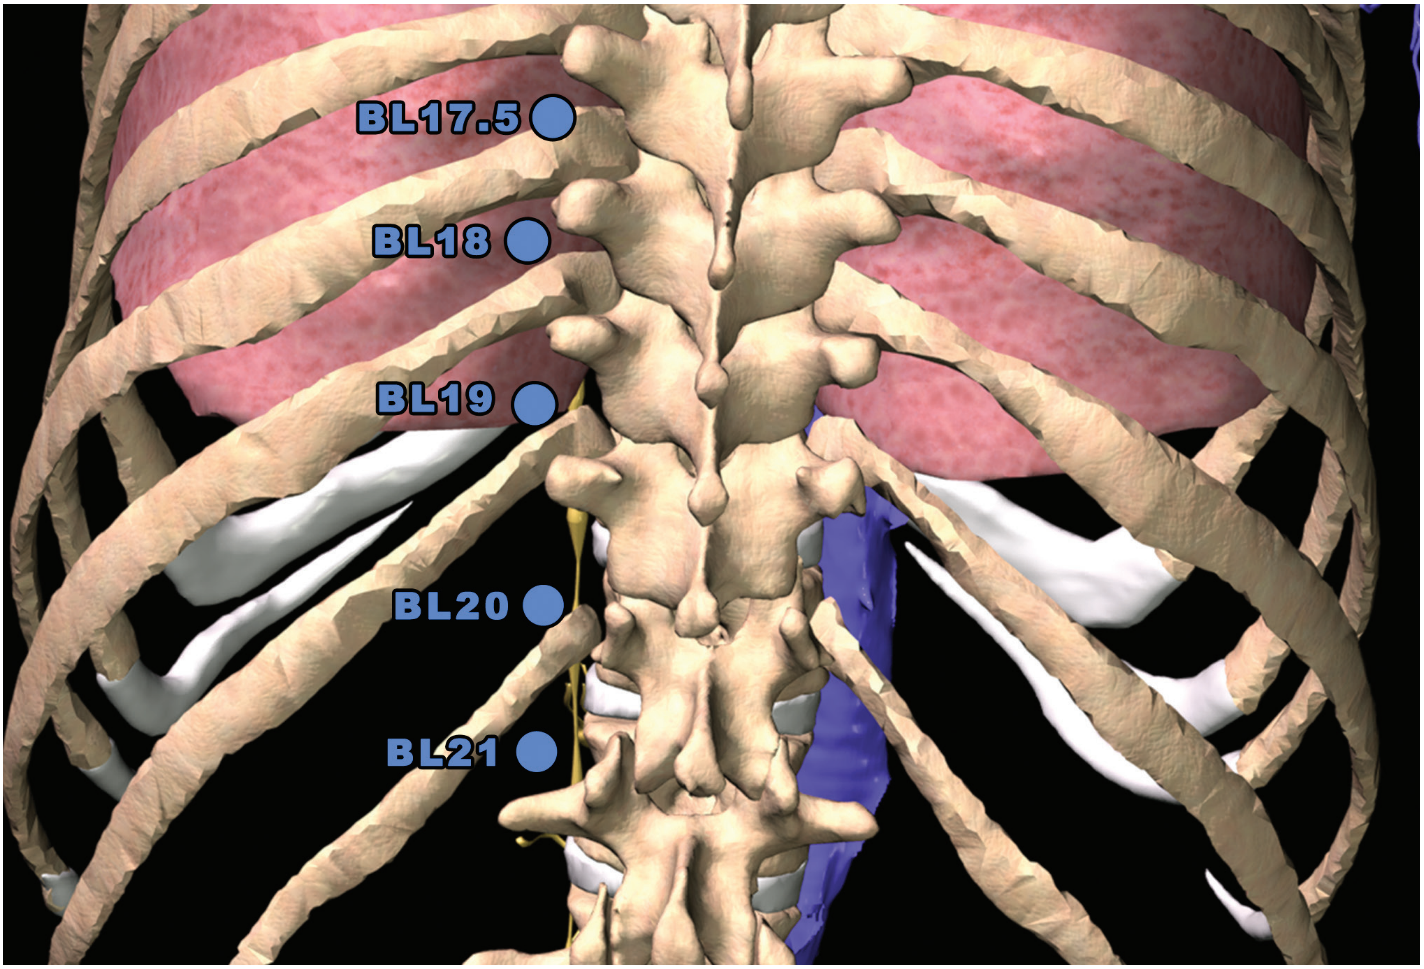

Figure 7-38B. This close-up of BL18 reveals the continuation of the paravertebral sympathetic chain ganglia, close to the inner BL channel.

greater needling safety. At the same time, muscles in the caudal thoracic region can develop numerous trigger points that issue back pain vertically from sacroiliac joint to shoulder or around the waist to the abdomen, roughly following the dermatome described by an entrapped spinal nerve branch.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T5-T9 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 18 acts as the Liver Back Shu point because the overlapping sympathetic nerve pathways supplying the liver arise from the T8 to T11 spinal cord segments.

Vessels

- **Ninth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Ninth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygos venous system, which conveys venous blood to the superior vena cava. The azygos vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Liver and gall bladder dysfunction:** BL 18, BL 19, LR 14, GB 24, ST 36.
- **Pain in the lateral costal region:** Palpate for trigger points, if tender within the T8-T10 dermatome, BL 18, with BL 17.5 and BL 19 as well as local tender areas.

BL 19

Dan Shu "Gall Bladder Shu"

On the thoracic vertebral region, 1.5 cun lateral to the caudal border of the T10 spinous process. Locate in the 10th intercostal space between the longissimus and iliocostalis thoracis muscle. View the distinct border between the two muscles in Figure 7-41 on the left side of the back.

CAUTION: Needle carefully to avoid pneumothorax.

Muscles

- **Trapezius muscle:** Inferior fibers depress the scapula and lower the shoulder.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm. The location of the serratus posterior inferior and the serratus posterior superior muscles suggests that they provide proprioceptive information to the spine that aids its stability.[1] Myofascial restriction likely contributes to back pain.
- Erector spinae muscles: Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: The longissimus thoracis muscle beneath BL 19 has continued to grow in thickness and strength as it descends the spine. (See Figure 7-41.) More muscle tissue beneath a point translates to greater needling safety. However, trigger point dysfunction manifests in this and surrounding muscles, as well, referring pain to the back, side, or abdomen.

In addition, BL 19 encounters the beginnings of the thoracolumbar fascia. The vertebral aponeurosis portion of the thoracolumbar fascia attaches medially to the spinous processes of the thoracic vertebrae. Its cranial portion blends with the deep fascia of the neck. Its caudal extent forms a continuous layer that covers the erector spinae muscle and descends toward the sacrotuberous ligament. The thoracolumbar fascia aids in stabilizing the lumbar spine through force adjustment. The fascia may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles.[2,3]

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.

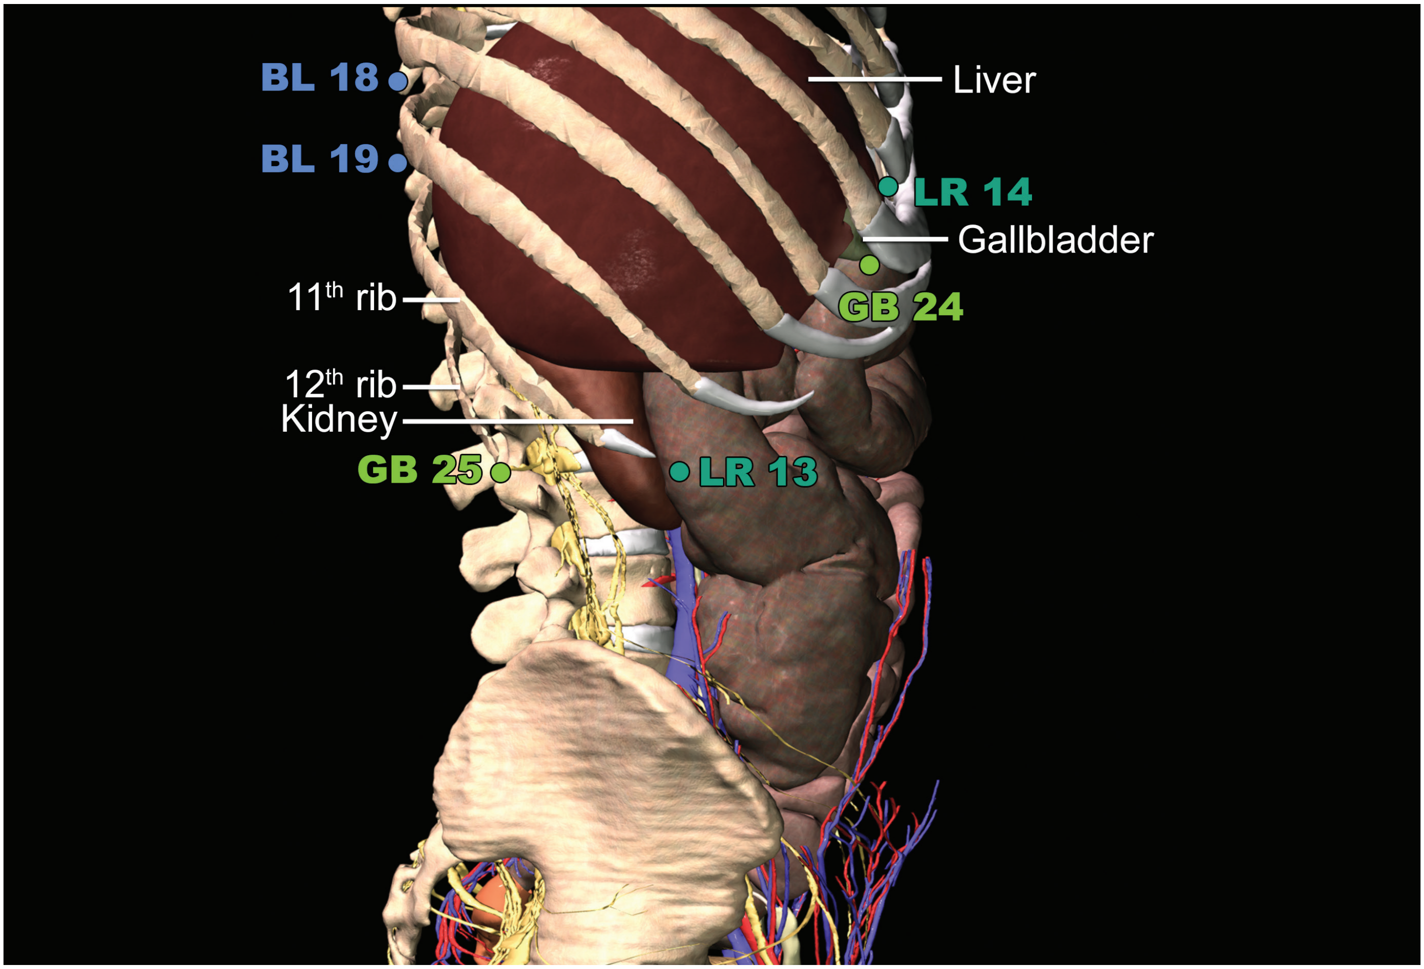

Figure 7-40. This right lateral view of the trunk depicts the way in which BL 19, the Back Shu point for the Gallbladder, rests near the same horizontal plane as the gallbladder itself, similar to how BL 18 overlays the liver. Note, as well, how the Front Mu pairs for BL 18 and BL 19 (i.e., LR 14 and GB 24, respectively, live along adjacent dermatomes.

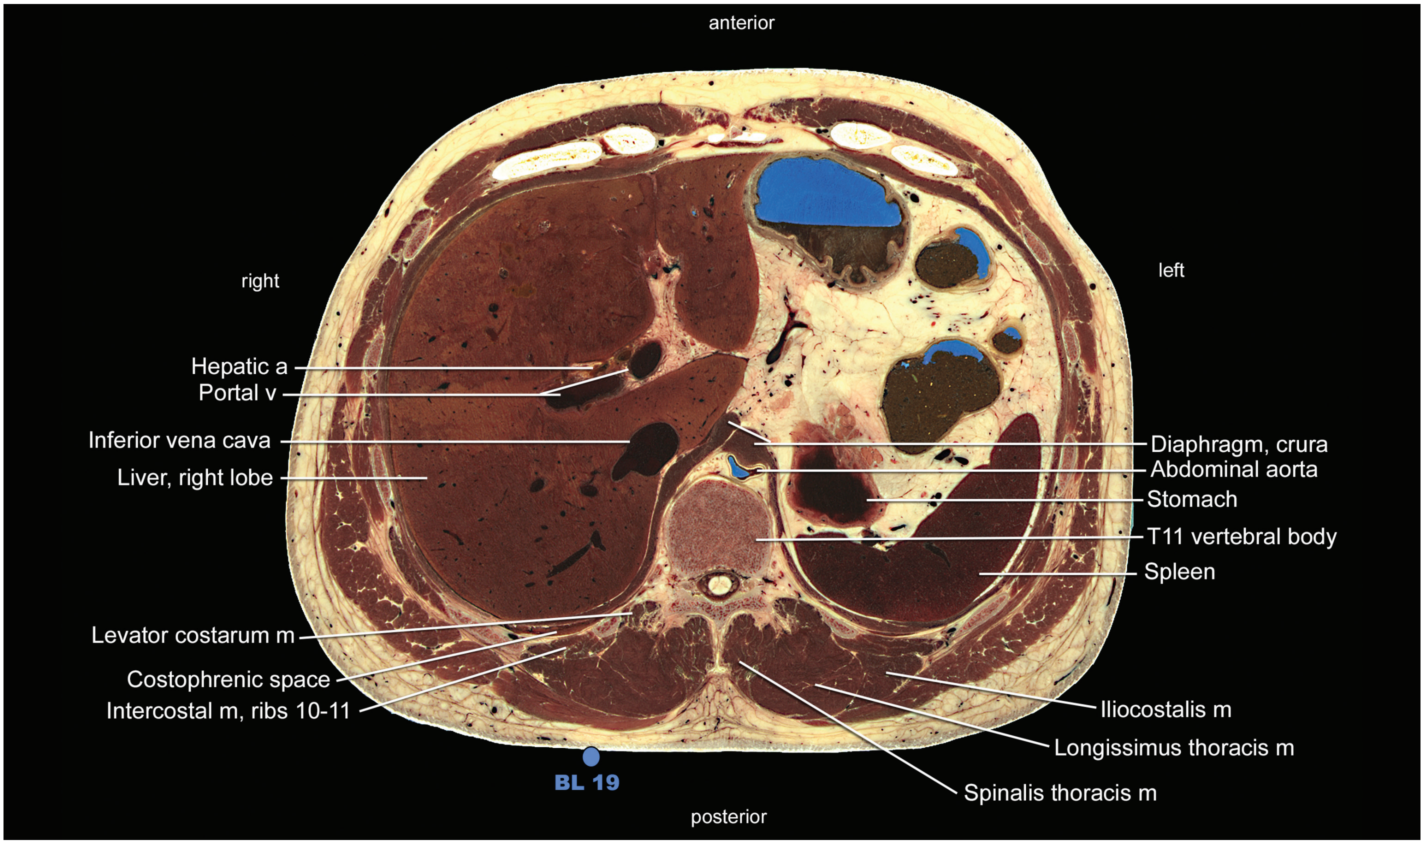

Figure 7-41. While the gallbladder does not appear in this cross section, BL 19 or "Gallbladder Shu", at the T10 dermatome, connects through somatovisceral and viscerosomatic reflexes to the gallbladder. That is, the T9-T11 dermatomes associate with the same spinal segments that issue sympathetics to the gallbladder. The powerful erector spinae muscles are growing in size as they migrate toward the lumbar levels.

- **T6-T10 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 19 acts as the Gallbladder Back Shu point in the T10 dermatome because the overlapping sympathetic nerve pathways supplying the liver arise from the T9 to T11 spinal cord segments.[4]

Vessels

- **Tenth posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Tenth posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Gall bladder problems (cholecystitis, cholelithiasis):** BL 19, BL 18, GB 24, GB 34, LR 14, ST 19, ST 36.[5]
- **Pain in the lateral costal region:** BL 19 if tender, along with other tender points in this and nearby dermatomes and myotomes.
- **Depression:** BL 15, BL 17, BL 18, BL 19, LI 4, LR 3, GV 20, Yintang.[6]

BL 20

Pi Shu "Spleen Shu"

On the thoracic vertebral region, 1.5 cun lateral to the caudal, or inferior, border of the T11 spinous process, in the last intercostal space. Locate between the longissimus and iliocostalis muscles.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (includes the transversospinal muscles):** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Transversospinal muscles:** These muscles originate from the transverse processes of a given vertebra and insert on the spinous processes of the upper vertebra. Transversospinal muscles include the semispinalis (capitis, cervicis, and thoracis), multifidus, and rotatores (cervicis, thoracis, and lumborum) muscles. All are innervated by dorsal primary rami of spinal nerves. The semispinalis arises from transverse processes of C4 to T12 vertebrae; the multifidus arises from the transverse processes of T1-T3; the rotatores arise from the transverse processes of vertebrae and insert onto the lower border and lateral portion of the lamina of the vertebra located above it (and only exist in the thoracic region).

The transversospinal muscles extend the head, cervical, and thoracic regions; they stabilize vertebral movements; assist with local extension and rotational movements. Rotatores may also function as proprioceptive organs.

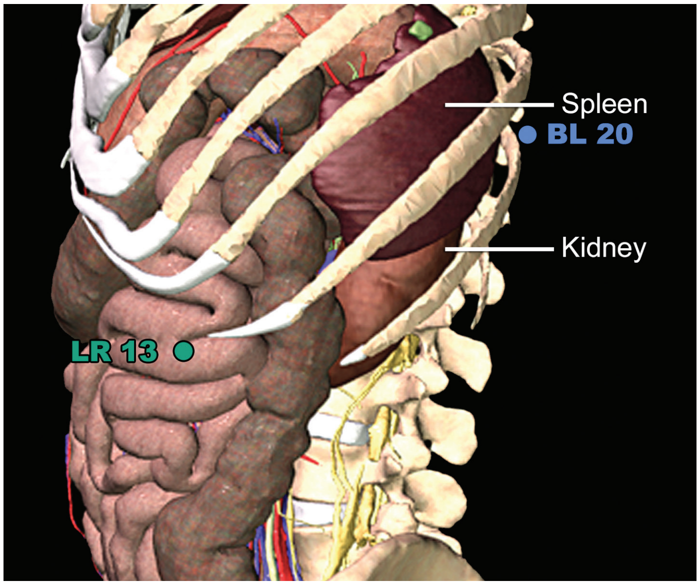

Figure 7-42. BL 20, "Spleen Shu" lands at the same level as the spleen (on the left side). It relates to its Front Mu partner, LR 13, by sharing spinal cord segments and adjacent dermatomes. The spleen organ receives sympathetic innervation from the T8 through T11 spinal cord segments, and BL 20 occupies the T11 dermatome.[11] The sympathetic chain and spinal nerves impacted by BL channel points show clearly in this image; look for them adjacent to the vertebral column cranial and caudal to the spleen.

Clinical Relevance: The longissimus and iliocostalis muscles at the level of BL 20 are becoming rounder in shape and often more resistant to needling because of their size, shape, and predisposition to developing myofascial restriction in this region. (See Figure 7-43 and compare with more cranial cross sections where the erector spinae muscles take on a flatter appearance.)

The thoracolumbar fascia begins to build in breadth and thickness, investing around the columns and laying atop of the paraspinal musculature. The thoracolumbar fascia aids in stabilizing the lumbar spine by adjusting forces placed upon it by musculature and ligamentous attachments. The fascia may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles.[8,9]

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T7-T11 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 20 serves as the Spleen Back Shu point in the T11 dermatome; the spleen organ receives its sympathetic nerve supply from the T8-T11 spinal cord segments, indicating neuroanatomic overlap and justification for its consideration as a neuroanatomic conduit of impulses from the soma to the viscera.[10]

Vessels

- **Eleventh posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **Eleventh posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Digestive problems:** lack of appetite, poor digestion, nausea, vomiting, dysentery, diarrhea, constipation: BL 20, LR 13, BL 21, CV 12, ST 36.

Figure 7-43. "Spleen Shu" lives at the same level as both the spleen and pancreas, seen in this cross section. The ancient Chinese mistook the pancreas and its effects on digestion for the spleen, to which they erroneously attributed activities such as, expressed in their metaphorical allegory, enzymatic degradation of food, its subsequent assimilation, and modulation of blood glucose levels to the spleen.[3]

Evidence-Based Applications

- Acupuncture at ST 36, BL 15, BL 20, HT 5, and PC 6 reduced the number of attacks per week in **angina pectoris** patients and reduced ST-segment depression during exercise, possibly indicating protection of the myocardium from ischemia.[1]
- Acupuncture and electroacupuncture at BL 17, BL 17.5, BL 20, BL 23, ST 36, and SP 6 effectively regulated levels of glucagon and immune factors, reduced blood coagulability, improved microcirculation, and heightened insulin sensitivity in **type-II diabetics**.[2]
- A case series reported that BL 20 and BL 21 effectively treated **stomach pain** from inflammation, ulcer, and carcinoma.[3]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[4]
- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis**.[5]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[6]
- Acupuncture at LI 4, LI 11, BL 13, BL 17, BL 20, ST 36, SP 6, SP 10, and GV 20 provided an immunomodulatory effect for patients with **lichen ruber planus**.[7]

BL 21

Wei Shu "Stomach Shu"

At the thoracolumbar junction, 1.5 cun lateral to the inferior border of the T12 spinous process. Locate in the groove between the longissimus and iliocostalis erector spinae muscles, caudal to the last rib.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: The longissimus and iliocostalis muscles at the level of BL 21 have grown rounder in shape. Their size and location predispose them to developing myofascial restriction. (See Figure 7-45.)

The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[7,8]

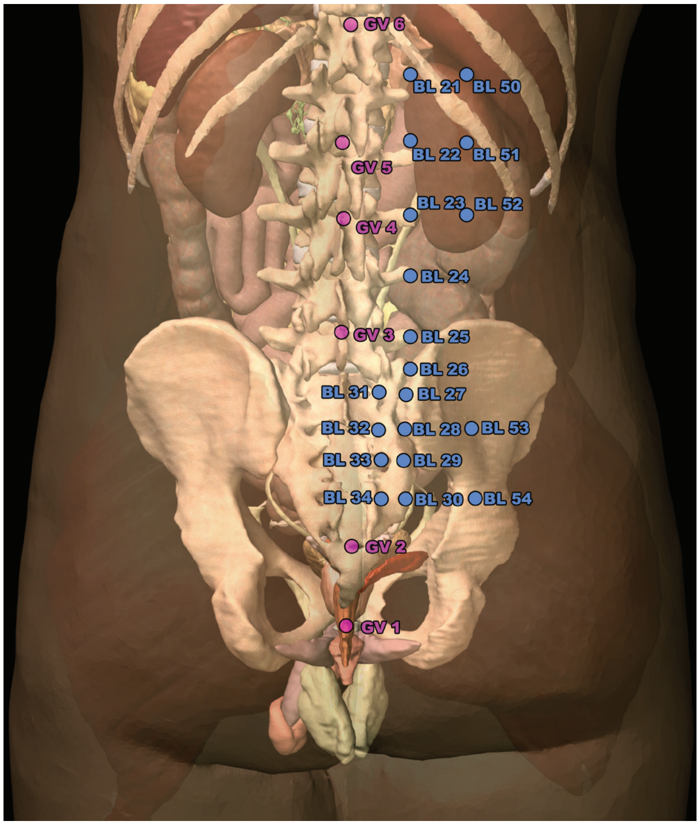

Figure 7-44. BL 21, "Stomach Shu", sits within the T12 dermatome. The stomach organ receives sympathetic nerve supply from the T5 through T12 spinal cord segments.[12] Thus, although the stomach usually does not extend to T12, its sympathetic nervous system connections associate, in part, with this level.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T7-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[9]

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 21 has been called the Stomach Back Shu point. It occupies the T12 dermatome, sharing spinal segmental innervation with the stomach organ, supplied by T5 through T12.[10]

Vessels

- **Twelfth posterior intercostal artery (subcostal artery):** Arises from the thoracic aorta. Supplies the muscles of the anterolateral abdominal wall.
- **Twelfth posterior intercostal vein (subcostal vein):** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava.

The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

From a singular vessel perspective, the subcostal vessels equate with the Dai Mai, or "belt meridian" vessel. Its physiologic effects pertain to the activities of the subcostal and L1 spinal nerves and associated sympathetic pathways.[11] Refer to section above under "Nerves" to review the activities of L1 that relate to the innervation of the pelvic region.

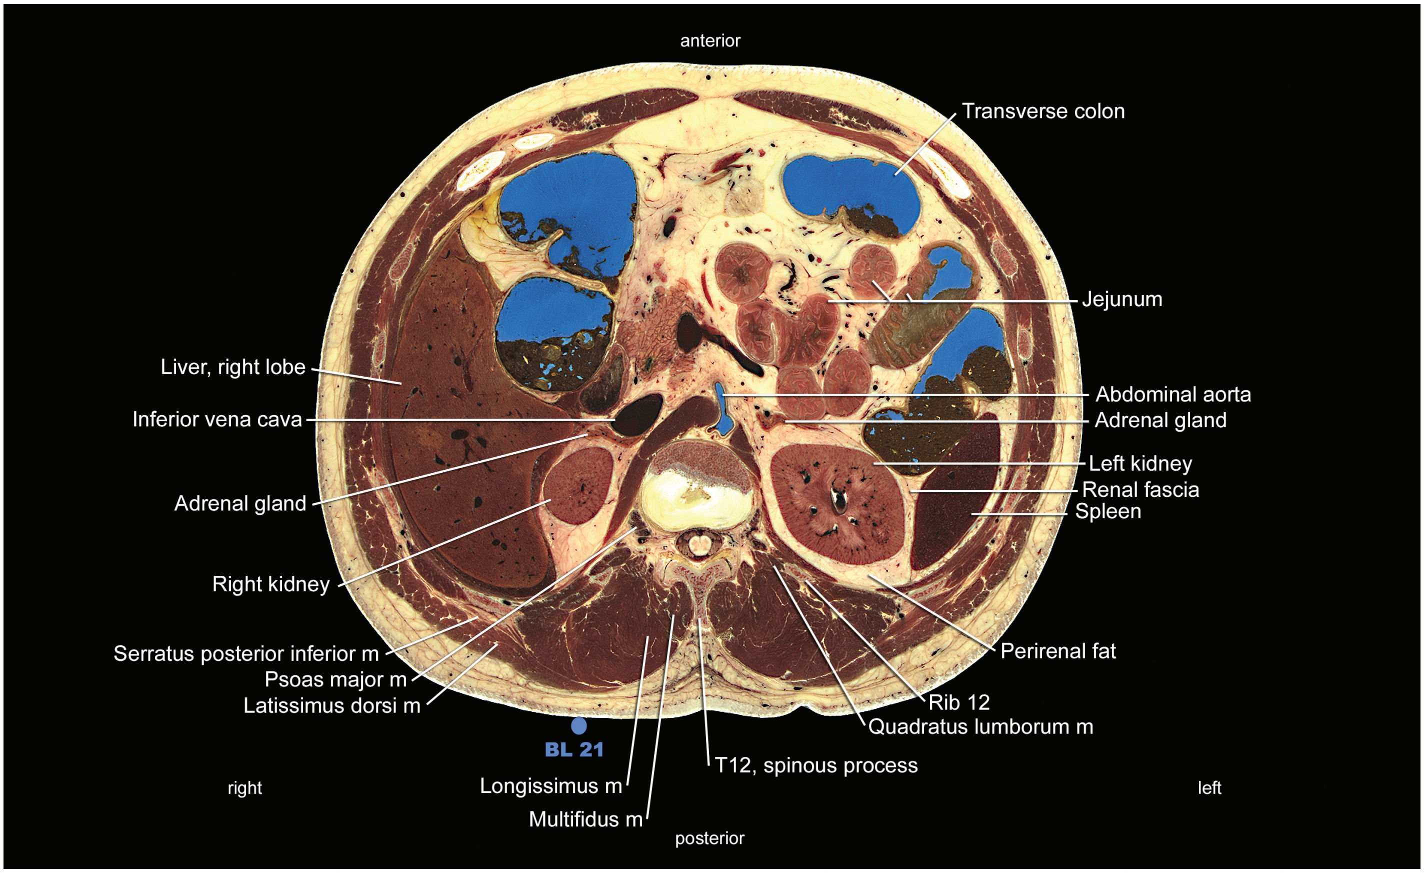

Figure 7-45. This cross-section clearly depicts several structures responsible for spinal integrity and postural support, including the erector spinae, the serratus posterior inferior, and quadratus lumborum musculature.

Indications and Potential Point Combinations

- **All gastrointestinal disorders:** lack of appetite, gastritis, nausea, fullness in stomach, vomiting, ulcers, diarrhea: BL 21, BL 20, CV 12, ST 36, LI 4, SP 6.
- **Low back pain:** BL 21, other BL line points that exhibit tenderness to palpation. GV points at levels with spinal pathology (other than cancer). BL 40, BL 60, KI 3.
- **Eructation and projectile vomiting stemming from a trigger point on the posterior abdominal wall:** BL 21.

Evidence-Based Applications

- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[1]
- Regarding the effects of acupuncture on canine **gastric motility** using ST 36, ST 40, ST 41, ST 42, ST 45, BL 12, or CV 12, only stimulation of ST 36 or BL 21 promoted gastric motility, whereas motility decreased with CV 12 stimulation. No significant changes in motility occurred after acupuncture at ST 40, ST 41, ST 42, or ST 45.[2]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[3]
- Acupuncture at CV 12, ST 36, PC 6, SP 4, BL 20, and BL 21, with either the adjunct points LI 11, GB 34, and LR 3 or CV 6, CV 4, and SP 6 improved gastric emptying in a case series of patients with **diabetic gastroparesis.**[4]
- A case series reported that BL 20 and BL 21 effectively treated **stomach pain** from inflammation, ulcer, and carcinoma.[5]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency** after transurethral resection of the prostate.[6]

BL 22

San Jiao Shu "Triple Burner Shu"

Accessory Back Shu point for the adrenal gland.

On the lumbar vertebral region, 1.5 cun lateral to the inferior border of the L1 spinous process. Find in the groove between the longissimus and iliocostalis lumborum muscles.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure.

Clinical Relevance: Excess tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[4] The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[5,6]

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: The epaxial muscles of the lumbar spine are larger than in the thoracic region; they can also harbor more trigger points and cause more nerve entrapment, as shown in Figure 7-47.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T8-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral

Figure 7-47. The spinal segmental relationship between BL 22 and L1 argues for the indications of BL 22, "Triple Heater Shu", for micturition, fluid distribution, and reproduction. The spinal segmental overlap of BL 22, the hypogastric nerve, and the adrenal gland provide the neuroanatomic basis for these endocrine and genitourinary applications.

ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature.

L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[7]

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 22 has been called the Triple Burner, or Triple Heater Back Shu point, associated strongly with the location and endocrine activities of the adrenal gland. It communicates with the T11-L1 dermatomes, sharing spinal segmental innervation with the adrenal gland, supplied by T5 through T11.

Vessels

- **First lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar psoas major muscle, psoas minor muscle, quadratus lumborum muscle, spinal cord and vertebral column, deep back muscles. The first lumbar may give rise to the inferior phrenic or middle suprarenal arteries. On occasion, one of the lumbar arteries provides the gonadal artery. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.
- **First lumbar vein:** The lumbar veins accompany the lumbar arteries and drain blood from the posterior body wall and the lumbar vertebral venous plexuses. The first and second lumbar veins drain into the ascending lumbar vein. The ascending lumbar veins feed into the azygous venous system. The lumbar veins communicate with the epidural venous plexus within the vertebral column.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Adrenal problems:** BL 22, BL 23, CV 5, GB 25, ST 36.
- **Back pain:** BL 22, BL 23, other local tender points in the region. Examine gluteal region for perpetuating trigger points. BL 40, BL 60.

Evidence-Based Applications

- Plum-blossom needle tapping at BL 22, BL 25, and Huatojiaji points from T8 to T12 helped improve symptoms in patients with ulcerative colitis.[1]

- Acupuncture provided an effective alternative to medication for the treatment of renal colic with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[2]

- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic oligoasthenoteratozoospermia (OAT syndrome).[3]

BL 23

Shen Shu "Kidney Shu"

On the lumbar vertebral region, 1.5 cun lateral to the inferior border of the L2 spinous process. Find in the groove between the longissimus and iliocostalis lumborum muscles.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure. The ventral layer attaches to the lumbar transverse processes and envelops the quadratus lumborum muscle. (See Figure 7-49.) The middle layer attaches from the tips of the lumbar transverse processes to the layers near the surface. The dorsal layer extends from the midline to more lateral regions, investing around the deep muscles of the back and providing attachments for the latissimus dorsi and serratus posterior inferior muscles.[31] The dorsal layer has a bilaminar aspect that includes an aponeurotic layer.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[32,33]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Excessive tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Some have equated the damage possible from heightened pressure in the lumbar paraspinal musculature, constrained by its fascial sleeve, to a "compartment syndrome".

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[34]

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: The epaxial muscles of the lumbar spine are larger than in the thoracic region; they can also harbor more trigger points and cause more nerve entrapment, as shown in Figure 7-49.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T8-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[35] The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

BL 23 serves as the Kidney Shu point. It occupies the L2 dermatome, sharing spinal segmental innervation with the kidney itself, supplied by spinal cord segments T10 through L2.[36]

Vessels

- **Second lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar vertebrae and the back muscles and abdominal wall. On occasion, one of the lumbar arteries provides the gonadal artery. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.

- **Second lumbar vein:** The lumbar veins accompany the lumbar arteries and drain the posterior body wall and the lumbar vertebral venous plexuses. The first and second lumbar veins drain into the ascending lumbar vein. The ascending lumbar veins become the azygous venous system. The lumbar veins communicate with the epidural venous plexus inside the vertebral column.
- **Ascending lumbar veins:** Communicating vessels between the common iliac, iliolumbar, and lumbar veins.[37] The ascending lumbar veins course ventral to the transverse processes of the lumbar vertebrae. They communicate at the cranial end with the subcostal vein; this juncture forms the azygous vein on the right and the hemiazygous vein on the left. At their caudal extent, the ascending lumbar veins connect to their respective common iliac veins. Many variations take place in the venous network of the back.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Knowledge of the communications and variable anatomy of the ascending lumbar and iliolumbar veins reduces the risk of injury, hemorrhage, and further complications during surgery of the retroperitoneal space and pelvis. Should vascular damage occur, acupuncture and related techniques applied to the BL channel along the lumbar spine could aid in the restoration of circulation in a region following iatrogenic injury to the dorsal lumbar region. BL 23, BL 24, and BL 25 offer good regional access to influencing the ascending lumbar vein regions by means of somatoautonomic reflexes.[38]

Indications and Potential Point Combinations

- **Renal problems**: BL 23, GB 25, GV 4.
- **Urinary disorders:** BL 23, BL 28, BL 32, KI 3, SP 6.
- **Reproductive problems**: BL 22, BL 23, GV 2, SP 4.
- **Low back pain:** BL 23, local myofascial trigger points, BL 40, BL 60, ST 36.
- **Exhaustion:** BL 23, BL 22.
- **Osteoporosis**: BL 23, ST 36.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[1]
- Acupuncture at BL 23, BL 28, and GV 4 or CV 4, CV 6, and SP 6 benefited patients with diurnal symptoms associated with **idiopathic bladder instability**.[2]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis** in women.[3]
- A case series indicated that point injection at BL 23, BL 24, and BL 52 alleviated or improved **nephritic colic**.[4]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency after transurethral resection of the prostate.**[5]
- Acupuncture at CV 4, BL 23, BL 25, and ST 25 offers an **alternative to pharmacologic sedation and analgesics in patients receiving extracorporeal shockwave lithotripsy** who are unable to tolerate medication.[6]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of r**ecurrent lower urinary tract infection in adult women**.[7]
- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[8]
- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[9]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction**.[10]
- May delay **aging of the reproductive system** in rats.[11]
- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes**.[12]
- A case series showed that acupuncture of BL 23 and BL 35 benefited men suffering from **chronic prostatitis**.[13]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combination with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome**, thereby offering an alternative to pharmacologic induction of ovulation.[14]
- Acupuncture at BL 23 and BL 35 outperformed acupuncture at CV 3, CV 4, SP 6, and SP 9 in treating **chronic prostatitis**, possibly because of the influence of BL 35 on the pelvic nerve plexus.[15]
- Electroacupuncture at BL 23 increased levels of luteinizing hormone releasing hormone (LHRH), luteinizing hormone (LH), follicle stimulating hormone (FSH), testosterone, and estradiol (E2) in aged rats; moxibustion at BL 23 also raised these levels. These results suggest that acupuncture and moxibustion may enhance the function of the **hypothalamus-pituitary-gonadal axis of aged rats**.[16]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with idiopathic **oligoasthenoteratozoospermia (OAT syndrome)**.[17]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36,

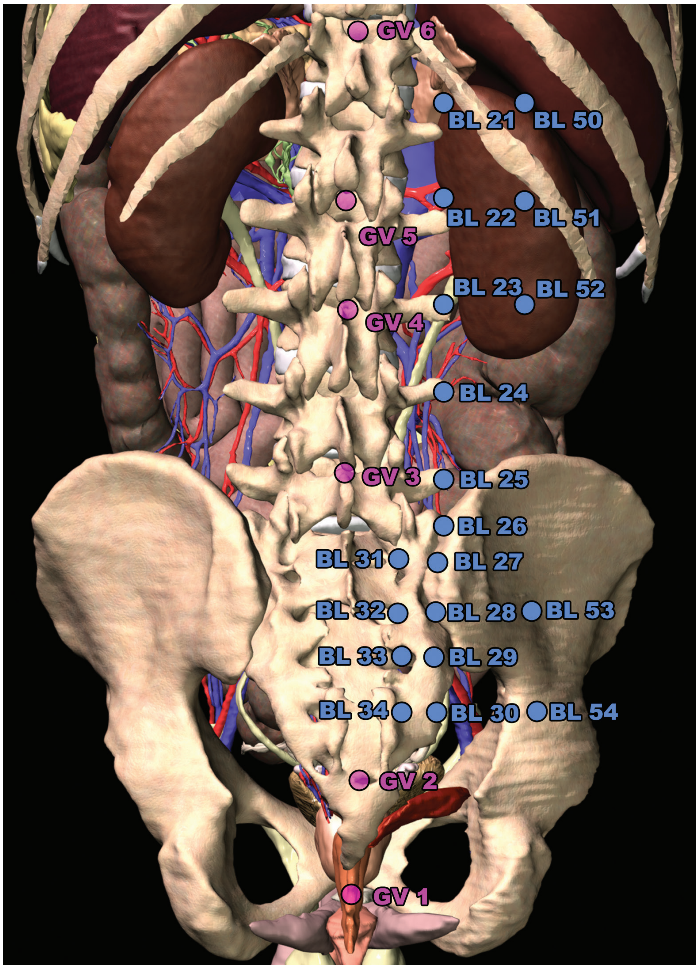

Figure 7-48A. Points that encircle the kidneys, creating the "kidney tiara" to improve renal function, include GV 4, BL 23, BL 52, and GB 25, stimulated bilaterally. This view portrays part of the kidney tiara in the context of neighboring GV and BL sites.

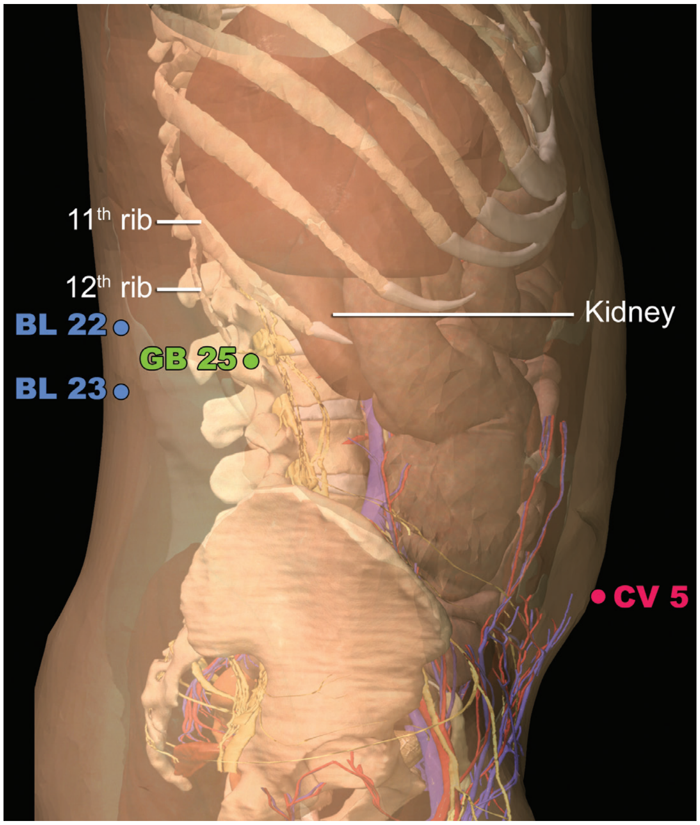

Figure 7-48B. This image exhibits the ways in which two Shu-Mu point pairs connect. BL 22 and CV 5 relate along the T11-L1 dermatomal band, associated with the adrenal gland that receives input from the sympathetic preganglionic fibers from T5-T11. BL 23 and GB 25 embrace the kidney, their associated organ. The kidney receives autonomic fibers from T10-L2; BL 23 lives at the L2 dermatome,[39] while GB 25 sits at the T11-12 level.

SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[18]

- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[19]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in **improvement in sperm quality**, specifically in the ultrastructural integrity of spermatozoa.[20]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain**: KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[21]
- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) **improved the orthopedic management of chronic low back pain.**[22]
- EA applied to BL 23, BL 24, BL 25, and BL 26 outperformed TENS for the treatment of **low back pain.**[23]
- EA at BL 23, BL 25, BL 40, and SP 6, combined with back exercises provided more relief of **chronic low back pain** and improvement in functional capacity compared to exercise alone; the benefits were maintained at a 3-month follow-up.[24]
- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[25]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[26]
- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain**, even at a 3 month follow-up.[27]
- Acupuncture and electroacupuncture at BL 17, BL 17.5, BL 20, BL 23, ST 36, and SP 6 effectively regulated levels of glucagon and immune factors, reduced blood coagulability, improved microcirculation, and heightened insulin sensitivity in **type-II diabetics.**[28]
- Acupuncture at BL 23, BL 24, BL 32, BL 39, and BL 54 improved four measures of bladder dysfunction (bladder compliance, maximal bladder capacity, bladder volume at desire to void, and urge to void) in patients with **diabetic bladder dysfunction.**[29]
- Acupuncture at BL 23 daily for 8 weeks **promoted bone formation**, restored bone volume, improved bone architecture, and reversed osteoporosis in senescence-accelerated mice. The mechanism presumably involved increasing testosterone secretion and reducing bone turnover.[30]

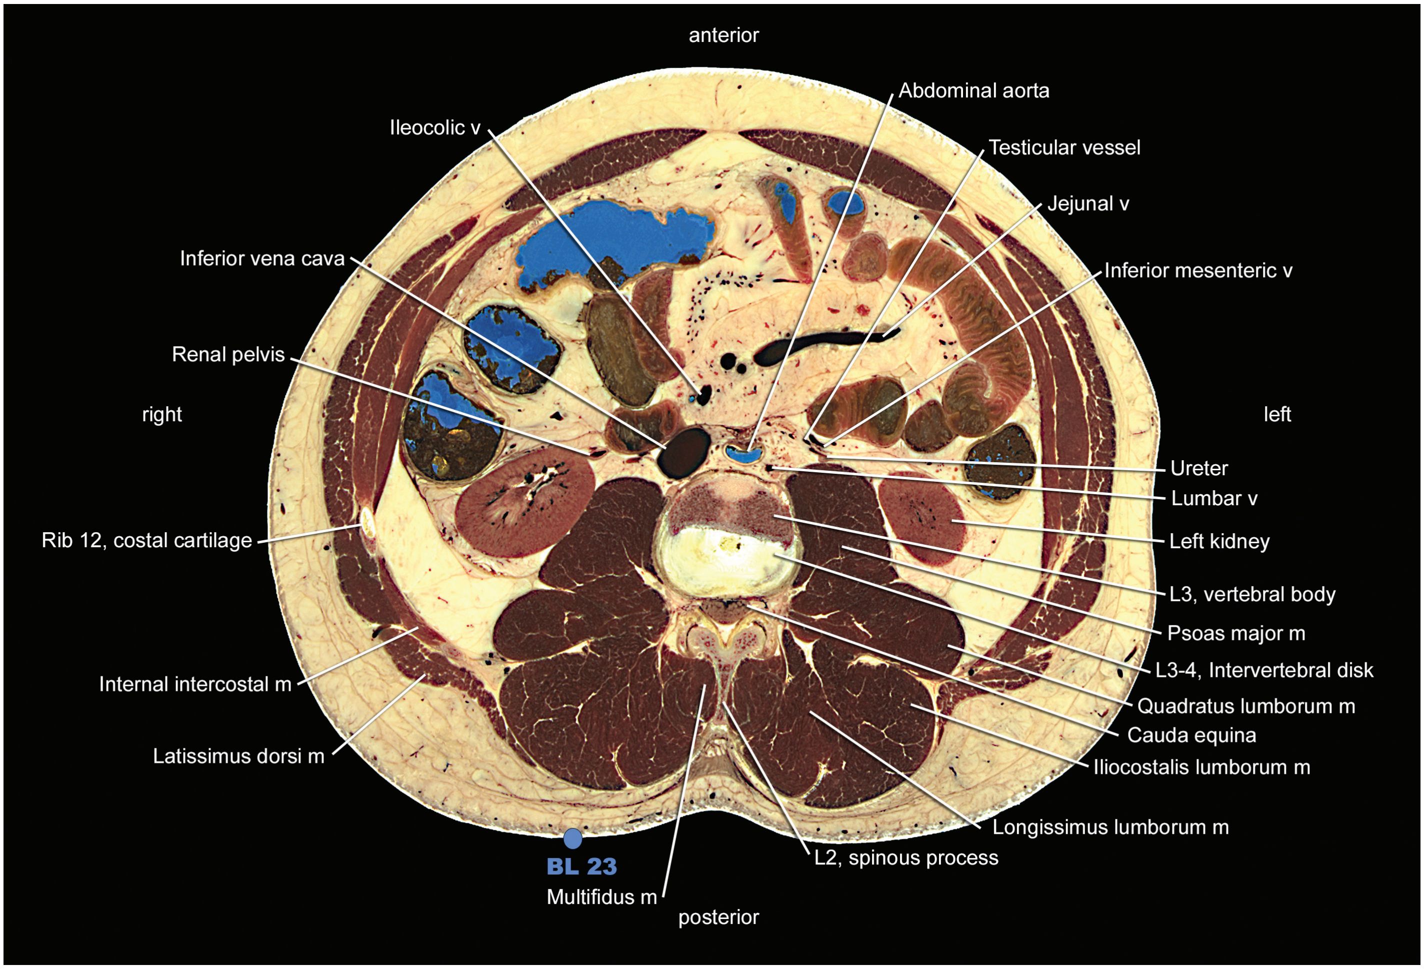

Figure 7-49. In addition to its indications for renal, genitourinary, and geriatric conditions, BL 23 serves as the most popular and likely the most vital point for the acupuncture treatment of low back pain. Note the dense expanse of paraspinal musculature, including the quadratus lumborum and psoas major muscles at this level. The tough thoracolumbar fascia surrounds and separates this cluster of muscles holding up the spine, providing support, and dissipating forces. When excessive tension accumulates in the thoracolumbar fascia, constriction of these structures causes pain, neuropathic insult, and functional impairment.

BL 24

Qi Hai Shu "Sea of Qi Shu"

On the lumbar vertebral region, 1.5 cun lateral to the caudal border of the L3 spinous process. Locate in the groove between the longissimus and iliocostalis lumborum muscles. See Figure 7-51 to further examine this myofascial cleavage plane that defines the inner Bladder channel trajectory.

CAUTION: Extra caution required in pregnancy on account of overlapping innervation with pelvic organ pathways.

Connective Tissues

- **Thoracolumbar fascia:** Encloses or envelops the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure. The ventral layer attaches to the lumbar transverse processes and envelops the quadratus lumborum muscle. (See Figure 7-51.) The middle layer attaches from the tips of the lumbar transverse processes to the layers near the surface. The dorsal layer extends from the midline to more lateral regions, wrapping around the deep muscles of the back and providing attachments for the latissimus dorsi and serratus posterior inferior muscles.[7] The dorsal layer has a bilaminar aspect that includes an aponeurotic layer. Observe the separation between the two layers as occurs in the cross section, Figure 7-51.

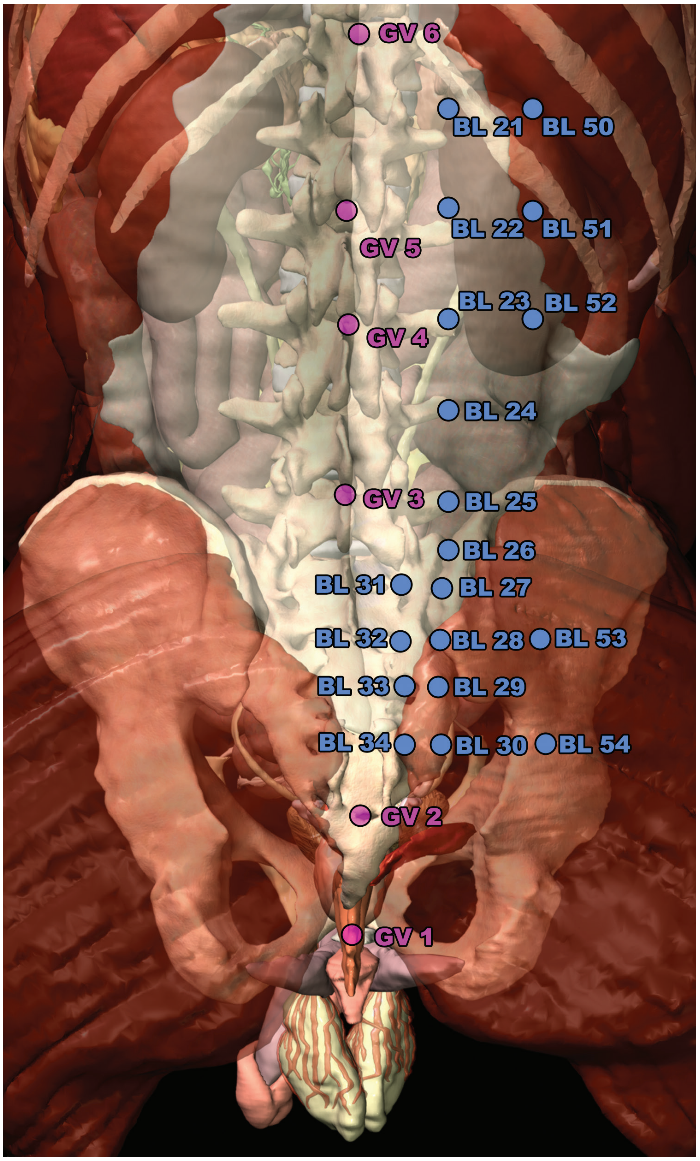

Figure 7-50A. BL 23 and BL 24 land at the levels where the thoracolumbar fascia reaches its broadest lateral extent, signifying this as a high-tension zone where numerous trajectories of force interweave within the muscles and connective tissue. This image exposes, as well, the caudal extent of the fascia onto the sacrum and ilia.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[8,9]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Excessive tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Some have equated the damage possible from heightened pressure in the lumbar paraspinal musculature, constrained by its fascial sleeve, to a "compartment syndrome".

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[10]

Muscles

- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: Strong, powerful, and potentially painful muscles dominate this layer of the lower trunk, as exposed by Figure 7-51. Inadvertent or intentional puncture of the psoas muscle, especially when instilling herbal mixtures, has caused psoas abscess formation.[11] Pyogenic abscess of the psoas can cause diagnostic confusion in the early stages, as patients receiving acupuncture in the low back already have pain, and practitioners may not recognize that a deep infection is developing. Left unrecognized and untreated, potential sequelae include necrotizing fasciitis, septicemia, septicemia, and death. In that acupuncture often involves needling several locations, bilateral and multiple abscesses may occur.

Nerves

- **T9-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami

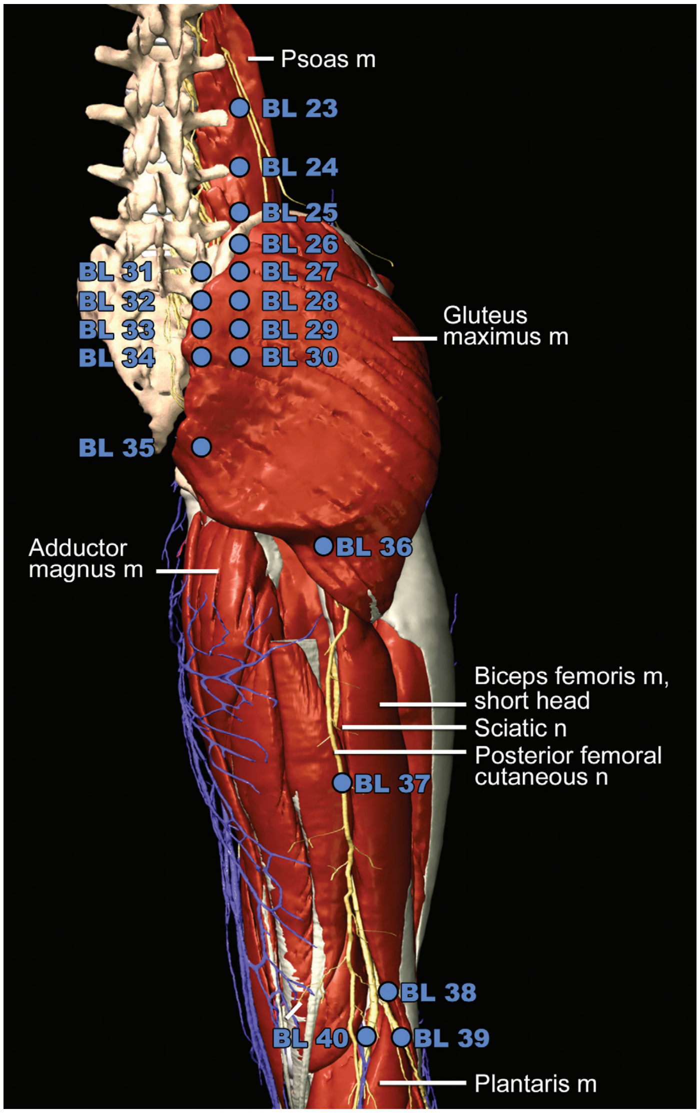

Figure 7-50B. Deep to the erector spinae and quadratus lumborum, the psoas muscle serves as a dominant hip and spine flexor. In the face of myofascial strain, the psoas can entrap lumbar nerve branches coursing through this strong, expansive muscle.[15] Neuromodulating these mid-lumbar spinal cord segments (i.e., countering central sensitization with acupuncture stimulation) would involve targeting the mid-lumbar points such as BL 23 and BL 24 to treat this condition neuroanatomically and following up with laser therapy unless contraindicated. However, the medical literature contains several reports of injury developing after acupuncture designed to reach the psoas muscle. The most common adverse effect involves abscess formation,[16] but pneumoretroperitoneum and polyarticular septic arthritis in conjunction with bilateral psoas abscesses[17] have also been reported.

communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora.

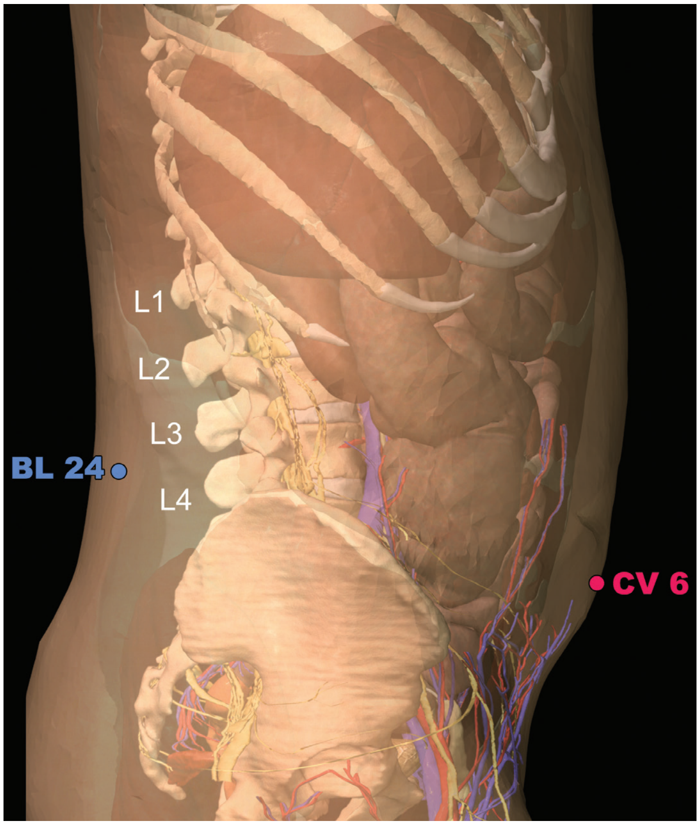

Figure 7-50C. The "Sea of Qi", CV 6, resides in the caudal belly where, in a pregnant female, one would note expansion as the developing fetus grows in size. BL 24, the Shu point associated with CV 6 ("Sea of Qi Shu") corresponds along a similar horizontal plane, spinal segmental innervation, and as the point where a gravid uterus accentuates the lumbar lordosis in the mid- and late-term.

Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[12] The L1 and L2 spinal cord segments provide sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.

- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **L3 spinal nerve:** Comprises part of the lateral femoral cutaneous, the femoral, the anterior femoral cutaneous, and the obturator nerves. The lateral femoral cutaneous nerve supplies the skin on the anterior and lateral regions of the thigh.

Figure 7-51. As shown in Figure 7-50A, the thoracolumbar fascia achieves its maximal width at the BL 23-BL 24 level. The three layers of the fascia become more visible in this cross section covering and enveloping the quadratus lumborum and the erector spinae as a group. The paraspinal retinacular sheath (PRS) constitutes a portion of the posterior (dorsal) layer of the thoracolumbar fascia. The PRS attaches at the midline onto the spinous process and extends to the transverse process, distinct from both the superficial (most dorsal) layer of the thoracolumbar fascia and the middle layer.[18] The PRS surrounds the paraspinal muscles that sit in the "cubby" formed by the spinous and transverse processes. This sheath fuses with the middle layer of the fascia that envelops the quadratus lumborum. This level at BL 24 depicts that separation clearly at the dorsal midline where the line points to the "Thoracolumbar fascia" near the bottom of the image.
This image also illustrates the facet joint of L3/L4. This raises the discussion point that acupuncturists should adhere to clean needling practices at all times. Failure to do so may lead to abscess formation or the development of septic arthritis in a facet joint.[19]

The femoral nerve supplies the anterior thigh muscles, the hip and knee joints, and the skin on the anteromedial surface of the thigh. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh as well.

The obturator nerve innervates the adductor longus, adductor brevis, gracilis, and pectineus muscles, as well as the obturator externus and adductor magnus muscles.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves.

Vessels

- **Third lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar vertebrae and the back muscles and abdominal wall. On occasion, one of the lumbar arteries provides the gonadal artery. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.
- **Third lumbar vein:** The lumbar veins drain the posterior body wall and the lumbar epidural vertebral venous plexuses.
- **Ascending lumbar veins:** Communicating vessels between the common iliac, iliolumbar, and lumbar veins.[13] The ascending lumbar veins course ventral to the transverse processes of the lumbar vertebrae. They communicate at the cranial end with the subcostal vein; this juncture forms the azygous vein on the right and the hemiazygous vein on the left. At their caudal extent, the ascending lumbar veins connect to their respective common iliac veins. Many variations take place in the venous network of the back.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Knowledge of the communications and variable anatomy of the ascending lumbar and iliolumbar veins reduces the risk of injury, hemorrhage, and further complications during surgery of the retroperitoneal space and pelvis. Should vascular damage occur, acupuncture and related techniques applied to the BL channel along the lumbar spine could aid in the restoration of circulation in a region following iatrogenic injury to the dorsal lumbar region. BL 23, BL 24, and BL 25 offer good regional access to influencing the ascending lumbar vein and other local vasculature by means of somatoautonomic reflexes.[14]

Indications and Potential Point Combinations

- **Low back pain:** BL 24, BL 23, other local tender points, BL 40, KI 3, ST 36.
- **Dysmenorrhea:** BL 24, BL 23, SP 6, CV 4.
- **Renal colic:** BL 23, BL 24, BL 52.

Evidence-Based Applications

- A case series indicated that point injection at BL 23, BL 24, and BL 52 alleviated or improved **nephritic colic.**[1]
- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[2]
- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[3]
- EA applied to BL 23, BL 24, BL 25, and BL 26 outperformed TENS for the treatment of **low back pain.**[4]
- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[5]
- Acupuncture at BL 23, BL 24, BL 32, BL 39, and BL 54 improved four measures of bladder dysfunction (bladder compliance, maximal bladder capacity, bladder volume at desire to void, and urge to void) in patients with **diabetic bladder dysfunction.**[6]

BL 25

Da Chang Shu "Large Intestine Shu"

On the lumbar vertebral region, 1.5 cun lateral to the caudal border of the L4 spinous process. Locate in the groove between the longissimus and iliocostalis lumborum muscles. See Figure 7-53 to further examine this myofascial cleavage plane that defines the inner Bladder channel trajectory.

CAUTION: Lumbar and sacral BL and GV points may affect uterine activity during pregnancy.

Connective Tissues

- **Thoracolumbar fascia:** Encloses or envelops the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure. The middle layer attaches from the tips of the lumbar transverse processes to the layers near the surface. The dorsal layer extends from the midline to more lateral regions, wrapping around the deep muscles of the back and providing attachments for the latissimus dorsi and serratus posterior inferior muscles.[14] The dorsal layer has a bilaminar aspect that includes an aponeurotic layer.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[15,16]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Excessive tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Some have equated the damage possible from heightened pressure in the lumbar paraspinal musculature, constrained by its fascial sleeve, to a "compartment syndrome".

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[17] Observe the separation between the dorsal layers of the thoracolumbar fascia in Figure 7-53.

Muscles

- **Erector spinae muscles:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Strong, powerful, and potentially painful

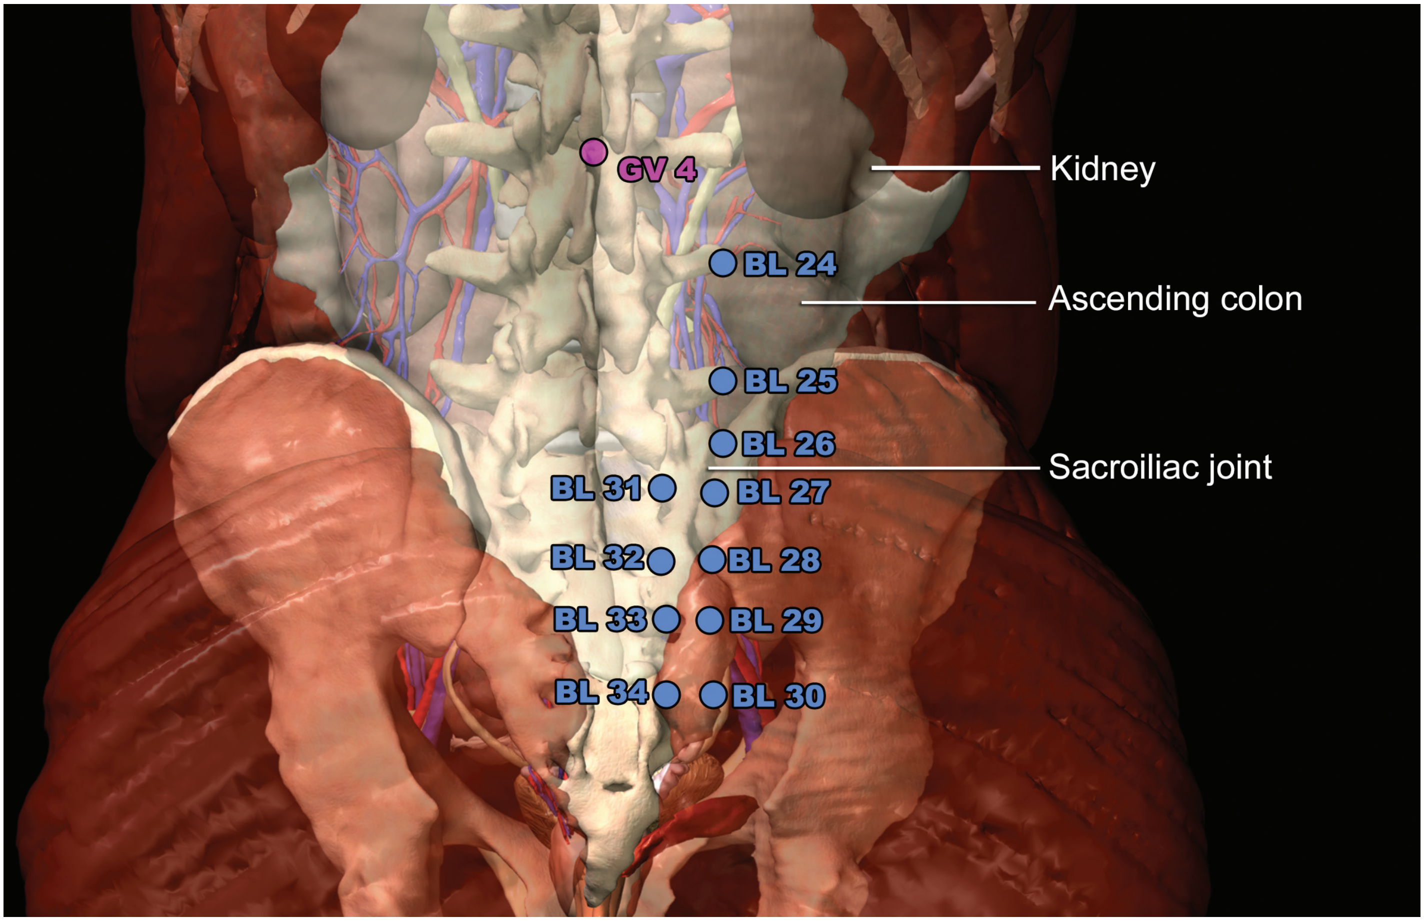

Figure 7-52. BL 25 treats both low back pain and constipation, which frequently co-occur reinforce one another. On the right side, BL 25 relates closely to the ascending colon. The left BL 25 impacts the descending colon, true to its title, "Large Intestine Shu".

muscles dominate this layer of the lower trunk, as shown in Figure 7-53. Although accessing the psoas muscle at this level would pose more difficulty than more cranial planes, inadvertent or intentional puncture of the psoas muscle, especially when instilling herbal mixtures, has caused psoas abscess formation.[18] Pyogenic abscess of the psoas can cause diagnostic confusion in the early stages, as patients receiving acupuncture in the low back already have pain, and practitioners may not recognize that a deep infection is developing. Left unrecognized and untreated, potential sequelae include necrotizing fasciitis, septicemia, septicemia, and death. In that acupuncture often involves needling several locations, bilateral and multiple abscesses may occur.

Nerves

- **T10-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **L3 spinal nerve**: Comprises part of the lateral femoral cutaneous, the femoral, the anterior femoral cutaneous, and the obturator nerves. The lateral femoral cutaneous nerve supplies the skin on the anterior and lateral regions of the thigh.

The femoral nerve supplies the anterior thigh muscles, the hip and knee joints, and the skin on the anteromedial surface of the thigh. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh as well.

The obturator nerve innervates the adductor longus, adductor brevis, gracilis, and pectineus muscles, as well as the obturator externus and adductor magnus muscles.

- **L4 spinal nerve:** The dorsal primary ramus supplies the muscles and skin of the back. L4 contributes to the obturator, anterior femoral cutaneous, and the femoral nerves, as described in the preceding paragraph. L4 forms part of the lumbosacral trunk, and contributes to the sciatic nerve, along with L5-S3. The sciatic nerve innervates the hamstring muscles and provides articular branches to the hip and knee joints.

Clinical Relevance: Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves.

BL 25, Large Intestine Shu, lies within the L4 dermatome. The sympathetic cell bodies in the thoracolumbar cord issue nerves to the large intestine from T8 to L4.[19]

Vessels

- **Fourth lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar vertebrae and the back muscles and abdominal wall. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.
- **Fourth lumbar vein:** The lumbar veins drain the posterior body wall and the lumbar epidural vertebral venous plexuses.
- **Ascending lumbar veins:** Communicating vessels between the common iliac, iliolumbar, and lumbar veins.[20] The ascending lumbar veins course ventral to the transverse processes of the lumbar vertebrae. They communicate at the cranial end with the subcostal vein; this juncture forms the azygous vein on the right and the hemiazygous vein on the left. At their caudal extent, the ascending lumbar veins connect to their respective common iliac veins. Many variations take place in the venous network of the back.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Knowledge of the communications and variable anatomy of the ascending lumbar and iliolumbar veins reduces the risk of injury, hemorrhage, and further complications during surgery of the retroperitoneal space and pelvis. Should vascular damage occur, acupuncture and related techniques applied to the BL channel along the lumbar spine could aid in the restoration of circulation in a region following iatrogenic injury to the dorsal lumbar region. BL 23, BL 24, and BL 25 offer good regional access to influencing the ascending lumbar vein and regional vasculature by means of somatoautonomic reflexes.[21]

Indications and Potential Point Combinations

- **Intestinal problems: constipation, diarrhea, abdominal pain or distention:** BL 25, ST 36, ST 37, CV 12.
- **Low back pain:** BL 25, BL 23, local tender points, BL 60, KI 3, ST 36.

Evidence-Based Applications

- Plum-blossom needle tapping at BL 22, BL 25, and Huatojiaji points from T8 to T12 helped improve symptoms in patients with **ulcerative colitis**.[1]
- Acupuncture and moxibustion at ST 25, ST 36, ST 37, CV 4, SP 6, SP 9, BL 20, BL 21, and BL 25 benefited patients with chronic nonspecific **ulcerative colitis** in a case series.[2]
- Acupuncture at CV 4, BL 23, BL 25, and ST 25 offers an **alternative to pharmacologic sedation and analgesics in patients receiving extracorporeal shockwave lithotripsy** who are unable to tolerate medication.[3]

Figure 7-53. The psoas muscle serves as a dominant hip and spine flexor that can entrap lumbar nerve branches coursing through it.[22] It should not, however, serve as a needling target for acupuncture. The medical literature contains reports of injury developing after acupuncture designed to reach the psoas muscle. Other methods such as laser therapy, careful massage, and stretching can address iliopsoas muscle shortening. Acupuncture to the lumbar epaxial muscles aids in reducing lumbar spinal cord wind-up and indirectly treats neuropathy in the lumbar spinal nerve branches.

- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[4]
- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[5]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain**: KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[6]
- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) **improved the orthopedic management of chronic low back pain.**[7]
- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[8]
- EA applied to BL 23, BL 24, BL 25, and BL 26 outperformed TENS for the treatment of **low back pain.**[9]
- EA at BL 23, BL 25, BL 40, and SP 6, combined with back exercises provided more relief of **chronic low back pain** and improvement in functional capacity compared to exercise alone; the benefits were maintained at a 3-month follow-up.[10]
- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[11]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[12]
- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain**, even at a 3 month follow-up.[13]

BL 26

Guan Yuan Shu "Pass Head Shu"

On the lumbar vertebral region, 1.5 cun lateral to the caudal border of the L5 spinous process. Locate along the sacroiliac groove.

CAUTION: Lumbosacral BL and GV points may affect uterine activity during pregnancy.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[4,5]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[6]

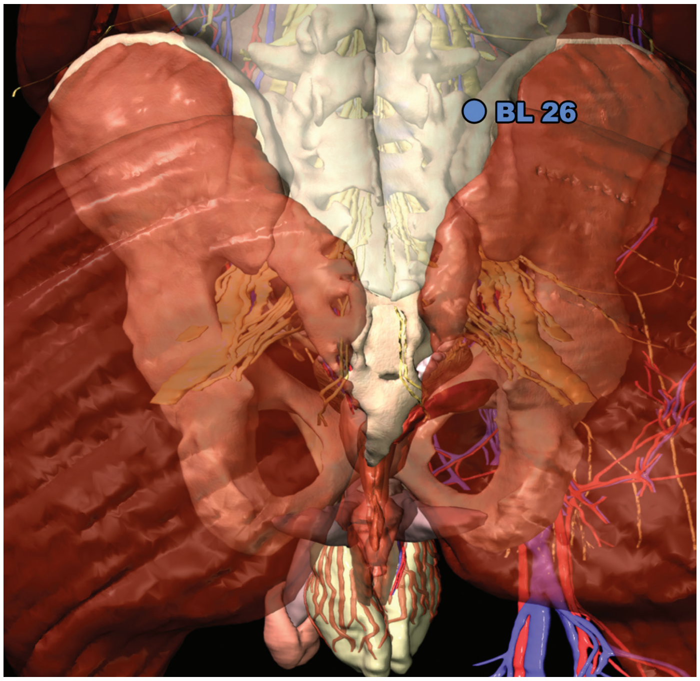

Figure 7-54. BL 26 lives near the sacroiliac joint, explaining its frequent application for low back pain and sacroiliac dysfunction.

Muscles

- **Erector spinae muscle group:** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Pain in the sacroiliac joint as well as pain that extends from the thoracolumbar region along the BL channel to the buttocks may originate in trigger points in the iliocostalis and longissimus lumborum, from BL 19 to BL 23. These trigger points may also issue referred pain around the trunk in a dermatomal fashion. Trigger points in the multifidus at or near BL 26 send pain locally, along the medial gluteal region, or perianal locations.

Iliopsoas trigger points also produce pain in the lumbar paraspinal group that outlines the muscle itself, as far caudal as the SI joint and cranial gluteal region. Other muscles that refer pain to the sacroiliac joint include the quadratus lumborum, gluteus maximus, gluteus medius, and gluteus minimus, and the piriformis.

In addition, rectus abdominis trigger points in the caudal attachment zones may cause pain to refer strongly to the lumbopelvic regions at the same level, including the sacroiliac joint. As such, practitioners treating patients complaining of sacroiliac pain should perform a comprehensive myofascial palpation evaluation in order to identify the true sources of pain and not just "chase" points along the joint line.

Nerves

- **T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies

the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.

- **L3 spinal nerve:** Comprises part of the lateral femoral cutaneous, the femoral, the anterior femoral cutaneous, and the obturator nerves. The lateral femoral cutaneous nerve supplies the skin on the anterior and lateral regions of the thigh.

The femoral nerve supplies the anterior thigh muscles, the hip and knee joints, and the skin on the anteromedial surface of the thigh. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh as well.

The obturator nerve innervates the adductor longus, adductor brevis, gracilis, and pectineus muscles, as well as the obturator externus and adductor magnus muscles.

- **L4 spinal nerve:** The dorsal primary ramus supplies the muscles and skin of the back. L4 contributes to the obturator, anterior femoral cutaneous, and the femoral nerves, as described in the preceding paragraph. L4 forms part of the lumbosacral trunk, and contributes to the sciatic nerve, along with L5-S3. The sciatic nerve innervates the hamstring muscles and provides articular branches to the hip and knee joints.
- **L5 spinal nerve:** The dorsal primary ramus supplies the muscles and skin of the back. L5 forms part of the lumbosacral trunk, and contributes to the sciatic nerve, along with L4-S3. The sciatic nerve innervates the hamstring muscles and provides articular branches to the hip and knee joints.
- **Medial superior cluneal nerve (L1-L3, terminal ends of dorsal rami):** The superior cluneal nerves supply the skin of the upper buttocks.

Clinical Relevance: Numerous nerves supply various structures within reach of an acupuncture needle entering BL 26. The innervation of the sacroiliac joint remains unclear, but likely involves a variety of lumbosacral spinal nerve branches.[7]

The medial branch of the superior cluneal nerve can experience entrapment near the iliac crest as it courses through a tunnel approximately 7 cm away from midline. When entrapment occurs, one finds thickened, tender area on palpation that feels like a trigger point would.[8] Patients with medial superior cluneal nerve entrapment (MSCNE) syndrome complain of pain at the medial portion of the iliac crest in either the gluteal or lumbosacral region. MSCNE syndrome is often confused with facet syndrome, lower lumbar disk disease, or an iliolumbar syndrome involving the iliolumbar ligament. The site where this occurs is close to both BL 26 and BL 27. Pain from MSCNE neuropathy radiates from the low back to the caudal thigh, following the BL channel. Fully and simultaneously flexing the ipsilateral hip and knee joints provides a provocation to the entrapment and assists in pinpointing MSCNE as the diagnosis.[9]

Damage to the superior cluneal nerves may occur during bone harvest of the iliac crest, warranting acupuncture and related techniques to reduce neuropathic pain and deafferentation.

Vessels

- **Fifth lumbar artery (branch of the median sacral artery):** Supplies the lower lumbar and lumbosacral area, including the vertebral body and vertebral end plate.
- **Fifth lumbar vein:** The lumbar veins drain the posterior body

wall and the lumbar epidural vertebral venous plexuses.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Sacroiliac pain:** BL 26, BL 27, BL 54, GB 30, BL 40.
- **Constipation:** BL 26, BL27, BL 28, ST 36, ST 37.
- **Micturition disorders:** BL 26, BL 23, BL 27, BL 28, KI 3, SP 6.

Evidence-Based Applications

- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[1]
- EA applied to BL 23, BL 24, BL 25, and BL 26 outperformed TENS for the treatment of **low back pain.**[2]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[3]

BL 27

Xiao Chang Shu "Small Intestine Shu"

At the level of S1 and the first dorsal sacral foramen, 1.5 cun lateral to the midline. Find at the sacroiliac joint line.

CAUTION: Failure to follow clean needling technique in acupuncture can lead to infectious consequences. Pursuant to deep needling of BL channel points over the sacroiliac joint (BL 27-30), septic sacroiliitis can result.[2,3]

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[4,5]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[6] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.[7]

Tendons

- **Erector spinae tendon:** The erector spinae tendon attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.

Clinical Relevance: Muscle shortening in the erector spinae group accentuates tension in the tendinous attachment on the sacrum, causing patients to complain of low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines.

Nerves

- **Middle cluneal nerves (S1-S3):** Supply the skin of the gluteal region. After the nerves exit their respective foramina, they traverse the erector spinae and overlying fascia to enter subcutaneous tissue superficial to the gluteus maximus muscle. The more cranial branches of the middle cluneal nerves often communicate with the medial superior cluneal nerve.[8]
- **Medial superior cluneal nerve (L1-L3, terminal ends of dorsal rami):** The superior cluneal nerves supply the skin of the upper buttocks.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S1 spinal nerve:** Contributes to several nerves, including the sciatic (L4-S3), the superior gluteal (L4-S1), and the inferior gluteal (L5-S2) nerves, the nerve to the piriformis (S1-S2), the nerve to the quadratus femoris and inferior gemellus (L4-S1), and the nerve to the obturator internus and superior gemellus (L5-S2).
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: The medial branch of the superior cluneal nerve can experience entrapment near the iliac crest as it

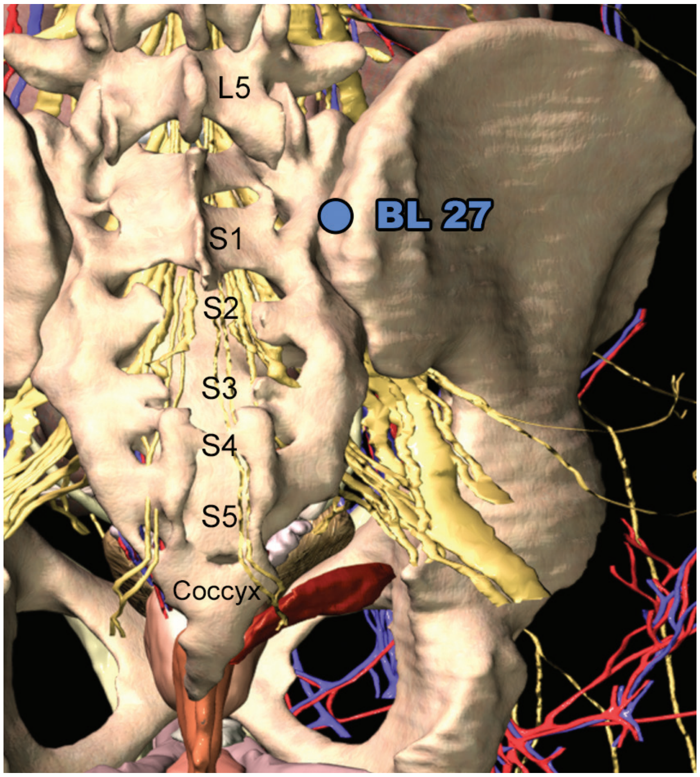

Figure 7-56. As the "Small Intestine Shu", BL 27 relates more to the sacral parasympathetic nuclei than to sympathetic nerve supply from the thoracolumbar region, since the small intestine receives sympathetic neurons from T5 to T12.[11]

Figure 7-57A. Like BL 26 through BL 30 associate with the sacroiliac joint. Note, as well, that at the level of this "Small Intestine Shu" point, the ileum (part of the small intestine) remains in the picture.

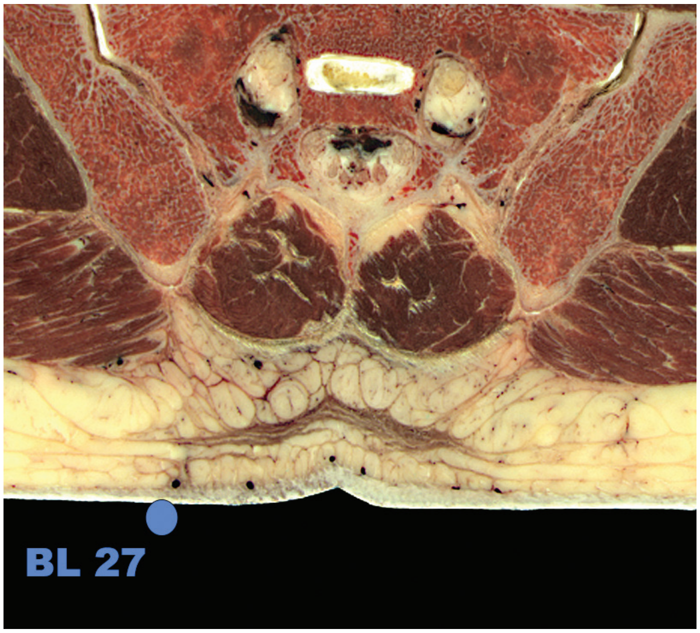

Figure 7-57B. Note how a gap exists in the fascia and subcutaneous tissue in this close-up view of Figure 7-57A. Morphologic changes called "sagging" in the thoracolumbar fascia at more cranial levels have been found on magnetic resonance imaging, seen as an abrupt bulging in the parasagittal planes of the dorsal layer and associated with pathologic changes of the thoracolumbar fascia. These degradations may indicate functional failure of the fascia and likelihood of progressive spinal instability.[12]

courses through a tunnel approximately 7 cm away from midline. When entrapment occurs, one finds thickened, tender area on palpation that feels like a trigger point would.[9] Patients with medial superior cluneal nerve entrapment (MSCNE) syndrome complain of pain at the medial portion of the iliac crest in either the gluteal or lumbosacral region. MSCNE syndrome is often confused with facet syndrome, lower lumbar disk disease, or an iliolumbar syndrome involving the iliolumbar ligament. The site where this occurs is close to both BL 26 and BL 27. Pain from MSCNE neuropathy radiates from the low back to the caudal thigh, following the BL channel. Fully and simultaneously flexing the ipsilateral hip and knee joints provides a provocation to the entrapment and assists in pinpointing MSCNE as the diagnosis.[10]

Damage to the superior cluneal nerves may occur during bone harvest of the iliac crest, warranting acupuncture and related techniques to reduce neuropathic pain and deafferentation.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Micturition disorders:** Dysuria, voiding dysfunction, enuresis: BL 27, BL 28, BL 32, KI 3, SP 6.
- **Low back pain:** Take BL 27 if tender and/or if one suspects sacroiliac-based pain. Add local trigger points as necessary, GB 30, BL 40.

Evidence-Based Applications

- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[1]

BL 28

Pang Guang Shu "Bladder Shu"

At the level of S2 and the second dorsal sacral foramen, 1.5 cun lateral to the midline. View the interplay of muscle borders, sacroiliac joint, and thoracolumbar fascia at this level in Figure 7-59. Locate near the sacroiliac joint.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum. Locate the thoracolumbar fascia on Figure 7-59.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[9,10]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[11] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.

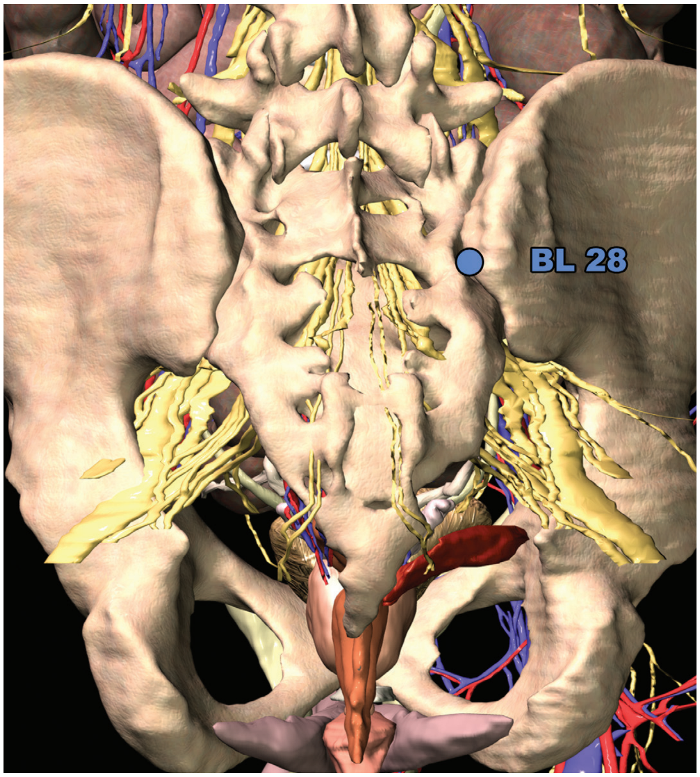

Figure 7-58. BL 28, "Bladder Shu", follows the BL line along the sacroiliac joint. Its dermatomal relationship to S2 overlaps the parasympathetic supply to the bladder that flows from the S2 through the S4 spinal cord segments. As such, it affects parasympathetic and somatic nerve control to the detrusor muscle of the bladder and external urethral sphincter, respectively. Of the 67 points constituting the BL channel, BL 28 represents the one point closely associated with its namesake organ. From a myofascial perspective, this area of gluteus maximus attachment can harbor trigger points that refer to the hip, gluteal crease, or coccyx.

Muscles and Tendons

- **Longissimus muscle:** Visible in Figure 7-59, the longissimus muscle blends with the iliocostalis lumborum and fuses with the thoracolumbar fascia.
- **Erector spinae tendon:** The erector spinae tendon attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.
- **Gluteus maximus muscle:** Extends the thigh and assists in lateral rotation.

Clinical Relevance: Muscle shortening in the erector spinae group accentuates tension in the tendinous attachment on the sacrum, causing patients to complain of low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines. Trigger points in the gluteus maximus muscle may refer to the hip, coccyx, or gluteal crease and also accentuate back pain. In the vicinity of BL 28, gluteus maximus trigger point pathology issues referred pain along the sacroiliac joint toward the intergluteal cleft (BL 35), down to the gluteal crease (BL 36) and proximal thigh (BL 37).

Nerves

- **Middle cluneal nerve (S1-S3):** Supplies the skin of the gluteal region.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior

femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.

- **S2 spinal nerve:** Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S2 contributes to the pudendal nerve (along with S3 and S4), which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. S2 also provides input to the sciatic nerve (L4-S3), the inferior gluteal nerve (see below), the nerve to the piriformis (S1,S2), the nerve to the obturator internus and the superior gemellus (L5-S2), the posterior femoral cutaneous nerve (S2,S3), and the perforating cutaneous nerve (S2,S3).
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: Middle cluneal nerve entrapment may cause low back pain, whether due to tension in the erector spinae group compressing the nerves or from gluteus maximus overload. Palpate for trigger points in the gluteus maximus, gluteus medius, and piriformis; deactivate accordingly.

BL 28 relates to the bladder organ through reflexes coursing through sacral spinal segments. Somatovisceral linkages connect stimulation at this point with the pudendal and pelvic splanchnic nerves, supporting communication between the central nervous system, the bladder, and its sphincters. This explains why BL 28 so often appears in point formulae for voiding dysfunction.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential PointCombinations

- **Genitourinary disorders, including prostatitis, erectile dysfunction, urinary retention or incontinence, genital sores or swelling, voiding dysfunction:** BL 28, BL 31, BL 32, BL 33, BL 34, BL 23, SP 6, KI 3, GV 20. For urinary retention, also consider CV 2, CV 3, CV 4, SP 9, BL 23, BL 28, BL 32, and BL 39.[13]
- **Low back pain:** BL 28, other tender trigger points, BL 23, GV 4. Examine the longissimus and gluteus maximus muscular attachments in the vicinity of BL 28.
- **Pelvic limb weakness and pain:** BL 28, BL 23, identify sources of weakness and pain, select points according to neuroanatomic distribution and spinal segmental nerve supply.
- **Hip problems and restriction:** BL 28, GB 29, GB 30, identify cause of hip pain, restriction, or dysfunction.

Evidence-Based Applications

- Neuroanatomically, acupuncture at BL 28 may support **sexual performance** through its influence on the pelvic nerve and inferior hypogastric ganglion.[1]
- Acupuncture at SP 6, BL 28, BL 39, and CV 4 provided significant improvement in women diagnosed as having **overactive bladder with urge incontinence**.[2]
- Acupuncture at BL 23, BL 28, and GV 4 or CV 4, CV 6, and SP 6 benefited patients with diurnal symptoms associated with **idiopathic bladder instability**.[3]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis** in women.[4]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[5]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[6]
- Electroacupuncture (at BL 23, BL 28, SP 6, and SP 9) in combination with manual acupuncture (at PC 6, TH 5, and GV 20) induced regular ovulations in some women with **polycystic ovary syndrome**, thereby offering an alternative to pharmacologic induction of ovulation.[7]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency** after transurethral resection of the prostate.[8]
- Electroacupuncture applied to SP 6, BL 28, and BL 32, five times weekly for 2 weeks increased spontaneous voiding volume and decreased postvoid residual urine volume in patients with acute **stroke.**[14]

BL 29

Zhong Lu Shu "Central Backbone Shu"

At the level of S3 and the third dorsal sacral foramen, 1.5 cun lateral to the midline. Locate near the sacroiliac joint.

Tendons and Muscles

- **Erector spinae tendon:** The erector spinae tendon attaches to the median sacral crest, to the spinous processes of the lumbar and the eleventh and twelfth thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.
- **Gluteus maximus muscle:** Extends thigh and assists in lateral rotation.
- **Piriformis muscle:** Attaches primarily to the inner surface of the sacrum; its tendon inserts onto the greater trochanter of the femur. The piriformis laterally rotates the thigh in the non-weightbearing limb with the hip extended. Aids in abduction when the hip is flexed at a ninety degree angle.

Clinical Relevance: Muscle shortening in the erector spinae group accentuates tension in the tendinous attachment on the sacrum, causing patients to complain of low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines. Trigger points in the gluteus maximus muscle may refer to the hip, coccyx, or gluteal crease and also accentuate back pain. In the vicinity of BL 29, gluteus maximus trigger point pathology issues referred pain along the sacroiliac joint toward the intergluteal cleft (BL 35), down to the gluteal crease (BL 36) and proximal thigh (BL 37). Piriformis trigger points at BL 29 refer pain strongly to the local region and more diffusely to the ipsilateral buttock and caudal thigh.

Nerves

- **Middle cluneal nerve (S1-S3):** Supplies the skin of the gluteal region.
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S1-S2 spinal nerves:** Supply the piriformis muscle.
- **S3 spinal nerve:** Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S3 contributes to the pudendal nerve (along with S2 and S4), which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. S3 also supplies the sciatic nerve (L4-S3), the nerves to the levator ani and coccygeus (S3,S4), the posterior femoral cutaneous nerve (S2,S3), and the perforating cutaneous nerve (S2,S3).

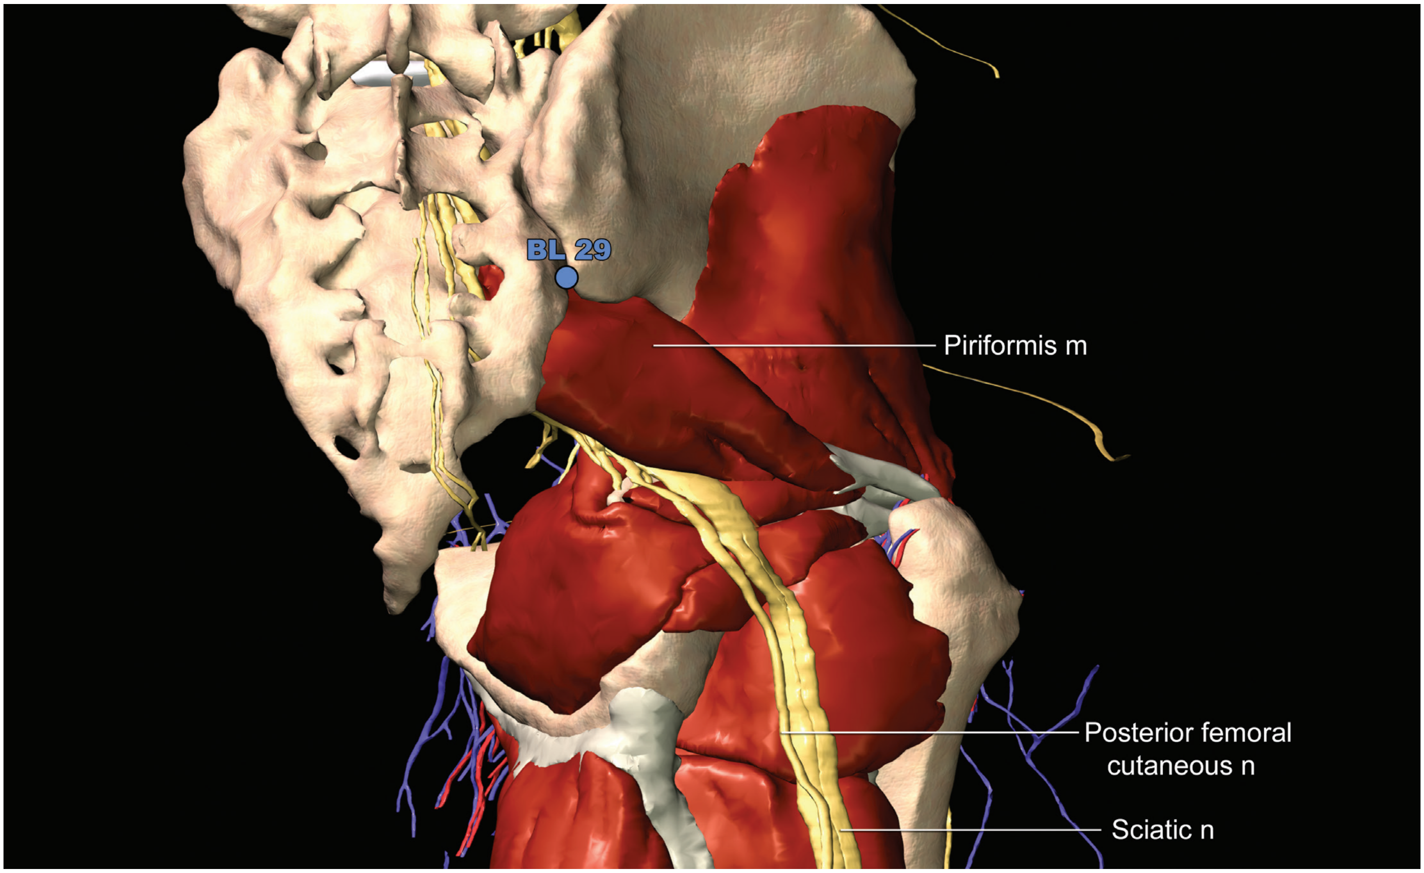

Figure 7-60. BL 29 constitutes the site of a significant attachment trigger point site for the piriformis muscle. Note the intersecting sacroiliac joint, piriformis muscle, and sciatic nerve.

Figure 7-61A. Both BL 29, "Central Backbone Shu", and BL 33, "Central Bone Hole", are located at the level of S3. The name "Zhong Lu" implicates the action of this acupuncture point on the erector spinae,[2] seen in Figure 7-61A. Trigger points in the gluteus maximus and piriformis muscles often contribute to pain in the back and pelvis.

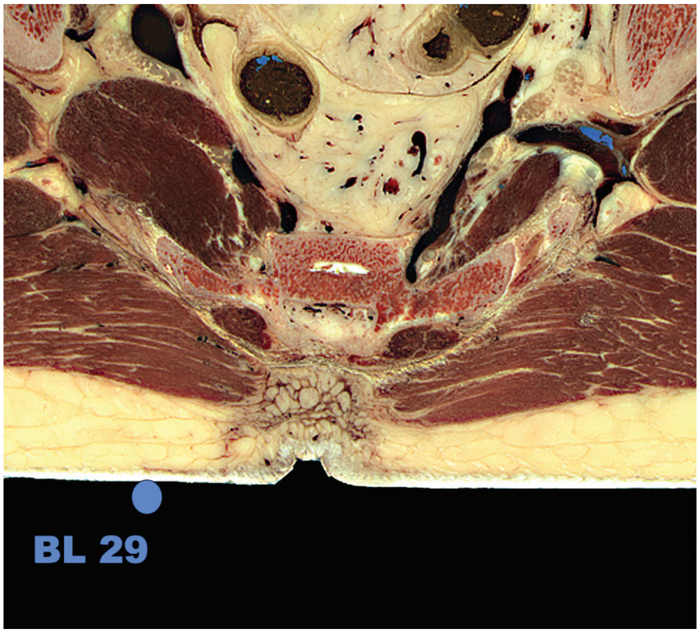

Figure 7-61B. This close-up of BL 29 and its cross sectional anatomical relationships reveals how a needle would sequentially impact the skin, subcutaneous tissue, gluteus maximus, and, depending on the angle of insertion, either the tail of the erector spinae, the sacroiliac joint, or fibers of the piriformis muscle.

- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: Middle cluneal nerve entrapment may cause low back pain, whether due to tension in the erector spinae group compressing the nerves or from gluteus maximus overload. Palpate for trigger points in the gluteus maximus, gluteus medius, and piriformis; deactivate accordingly.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Local and radiating pain, sciatica:** BL 29, BL 30, BL 54, GB 30.
- **Hemorrhoids:** BL 29, BL 30, BL 35, GV 1.
- **Piriformis myofascial dysfunction causing sciatica:** BL 29, BL 30, GB 30, GB 29, massage and laser therapy to the region. BL 40, BL 36.

Evidence-Based Applications

- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain**: KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[1]

BL 30

Bai Huan Shu "White Ring Shu"

At the level of the S4 and the fourth dorsal sacral foramen, 1.5 cun lateral to the midline, at the level of the sacral hiatus (GV 2).

Ligaments

- **Sacrotuberous ligament:** Provides support and resiliency to the sacroiliac region. Demonstrates broad attachments to the ilium, sacrum, coccyx, and ischium.[1] The ligament closely associates with the long head of the biceps femoris muscle as well as other ligaments and muscles.
- **Sacrospinous ligament:** Provides support and resiliency to the sacroiliac region. Inserts on the medial edge

Clinical Relevance: The sacrospinous ligament can compress either the pudendal or sciatic nerve, causing pain, neuropraxia, and pelvic or pelvic limb dysfunction.[2] Acupuncture, massage, and/or laser therapy will aid in releasing tension on the nerves and assist in resolution of the entrapment.

Tendons and Muscles

- **Erector spinae tendon:** The erector spinae tendon attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.
- **Gluteus maximus muscle:** Extends the thigh and assists in lateral rotation.
- **Piriformis muscle:** Attaches primarily to the inner surface of the sacrum; its tendon inserts onto the greater trochanter of the femur. The piriformis laterally rotates the thigh in the non-weightbearing limb with the hip extended. Aids in abduction when the hip is flexed at a ninety degree angle.

Clinical Relevance: Muscle shortening in the erector spinae group accentuates tension in the tendinous attachment on the sacrum, causing patients to complain of low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines. Trigger points in the gluteus maximus muscle may refer to the hip, coccyx, or gluteal crease and also accentuate back pain. In the vicinity of BL 29, gluteus maximus trigger point pathology issues referred pain along the sacroiliac joint toward the intergluteal cleft (BL 35), down to the gluteal crease (BL 36) and proximal thigh (BL 37). Piriformis trigger points at BL 29 refer pain strongly to the local region and more diffusely to the ipsilateral buttock and caudal thigh.

Nerves

- **Middle cluneal nerve (S1-S3):** Supplies the skin of the gluteal region.

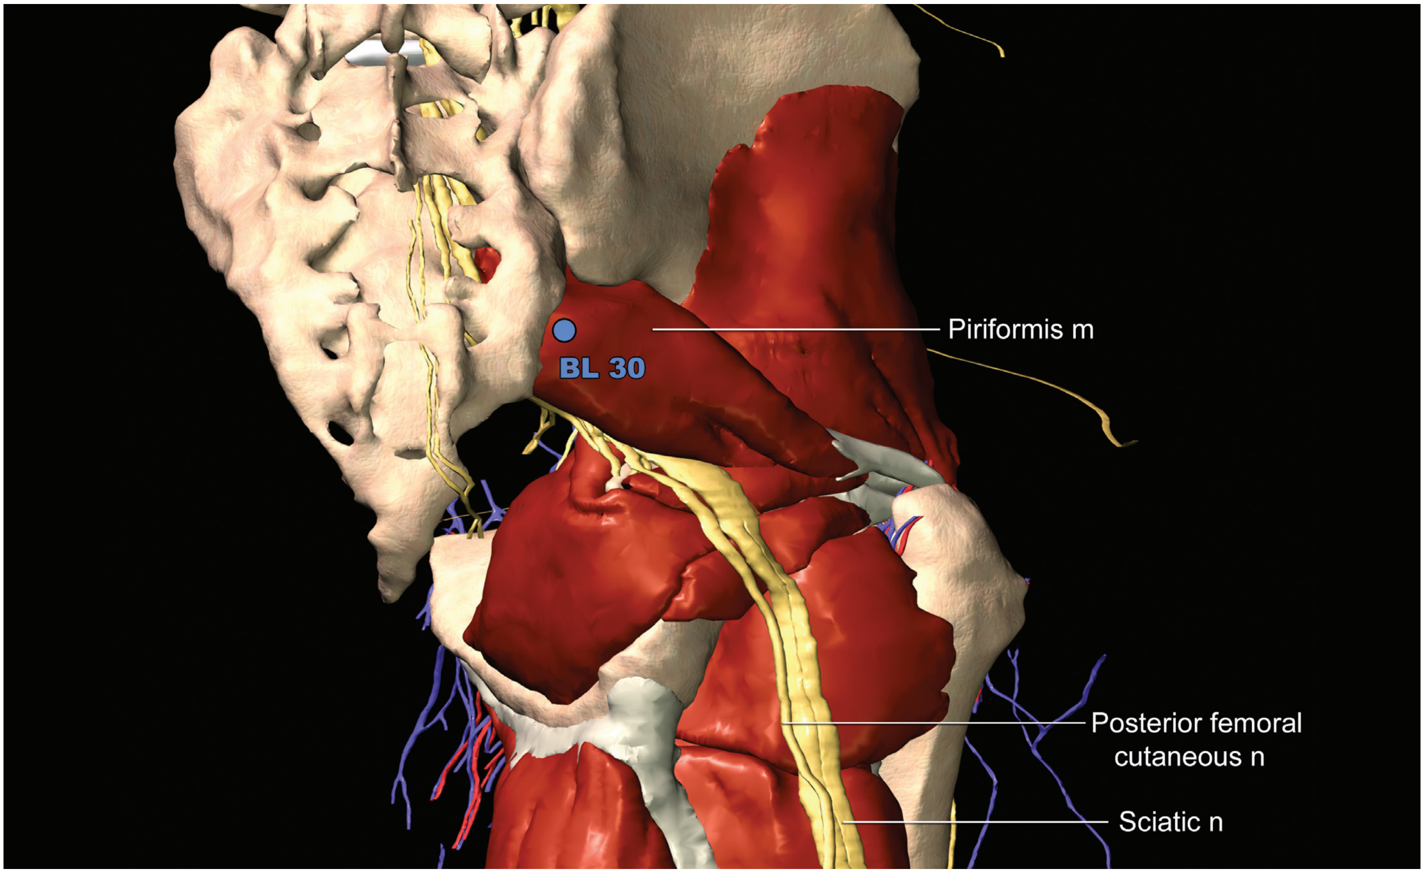

Figure 7-62. BL 30, lands squarely in the middle of the piriformis muscle, near to where it inserts onto the sacrum, highlighting its significance for piriformis dysfunction and sciatic nerve compression.

- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S1-S2 spinal nerves:** Supply the piriformis muscle.
- **S4 spinal nerve**: Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S4 contributes to the pudendal nerve (S2-S4), which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. S4 also supplies fibers to the nerves to the levator ani and coccygeus (S3,S4).
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.
- **Pudendal nerve (S2-S4):** The chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. The pudendal nerve passes between the piriformis muscle and the coccygeus muscle. It branches into the inferior hemorrhoidal nerve, the perineal nerve, and the dorsal nerve of the penis or clitoris. The inferior hemorrhoidal nerve communicates with the perineal branch of the posterior femoral cutaneous nerve and the posterior scrotal nerves. The perineal nerve's deep branch supplies the bulbocavernosus muscle, the corpus cavernosum urethrae, and the mucous membrane of the urethra. The dorsal nerve of the penis gives off a branch supplying the corpus cavernosum of the penis and ends on the glans.

Clinical Relevance: Middle cluneal nerve entrapment may cause low back pain, whether due to tension in the erector

spinae group compressing the nerves or from gluteus maximus overload. Palpate for trigger points in the gluteus maximus, gluteus medius, and piriformis; deactivate accordingly.

Pudendal nerve entrapment leads to pain in the rectum, scrotum/labia, or penis/clitoris. Pain worsens when seated and subsides when standing or lying down.[3] The two principal sites of pudendal nerve entrapment involve 1) between the sacrotuberous and sacrospinous ligaments and 2) in the pudendal canal.

Vessels

- **Inferior gluteal artery:** Supplies the pelvic diaphragm (which includes the coccygeus and levator ani muscles), the piriformis, quadratus femoris, proximal hamstring, and gluteus maximus muscles as well as the sciatic nerve.
- **Inferior gluteal vein:** Drains blood from the gluteal region.
- **Internal pudendal artery:** The main artery to the perineum (includes muscles and skin of urogenital and anal triangles and the erectile bodies).
- **Internal pudendal vein:** Drains blood from the external genitalia.

Clinical Relevance: Soft tissue dysfunction in this region, along with heightened tension in the ligamentous attachments to the sacrum, may compress vessels as well as nerves. Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and promoting tissue recovery.

Indications and Potential Point Combinations

- **Prostate problems:** BL 30, BL 34, BL 35, GV 1.
- **Local and radiating pain, sciatica:** BL 30, BL 29, BL 54, GB 30.
- **Hemorrhoids, rectal prolapse:** BL 30, BL 35, GV 1.
- **Urogenital and anorectal pain:** BL 30, BL 35, local trigger points and myofascial release.
- **Piriformis myofascial dysfunction causing sciatica:** BL 29, BL 30, GB 30, GB 29, massage and laser therapy to the region. BL 40, BL 36.

BL 31

Shang Liao "Upper Bone Hole"

Over the 1st dorsal sacral foramen, approximately midway between the midline (GV) and the posterior superior iliac spine (PSIS). The PSIS shows prominently in Figure 7-65 as the bony prominence to the right of BL 31, near the caudal end of the iliac crest.

While BL 31-34 relate to the dorsal sacral foramina, BL 27, BL 28, BL 29, and BL 30 follow the sacroiliac joint.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[3,4]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[5] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.[6]

Muscles

- **Longissimus muscle:** The longissimus attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.

Clinical Relevance: Muscle shortening in the erector spinae group, including the longissimus, accentuates tension affecting its tendinous attachment on the sacrum. This can cause low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines.

Nerves

- **Middle cluneal nerves (S1-S3):** Supply the skin of the gluteal region. After the nerves exit their respective foramina, they traverse the erector spinae and overlying fascia to enter subcutaneous tissue superficial to the gluteus maximus muscle. The more cranial branches of the middle cluneal nerves often communicate with the medial superior cluneal nerve.[7]
- **Medial superior cluneal nerve (L1-L3, terminal ends of dorsal rami):** The superior cluneal nerves supply the skin of the upper buttocks.
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S1 spinal nerve:** Contributes to several nerves, including the sciatic (L4-S3), the superior gluteal (L4-S1), and the inferior gluteal (L5-S2) nerves, the nerve to the piriformis (S1-S2), the nerve to the quadratus femoris and inferior gemellus (L4-S1), and the nerve to the obturator internus and superior gemellus (L5-S2).
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: Nerve entrapments in this region can produce pain that patients interpret as either of musculoskeletal or pelvic organ origin. Usually, freeing the nerve requires a multiplicity of needling sites along with massage and/or laser therapy to return slack to the tissues compressing the nerves.

Neuromodulation for reproductive problems and voiding dysfunction implements points over the sacrum (BL 27-34) to influence organ function in the pelvis through somatovisceral reflexes. Abnormalities in these same organs may sensitize the dorsal sacral spinal nerves, causing tenderness to palpation.

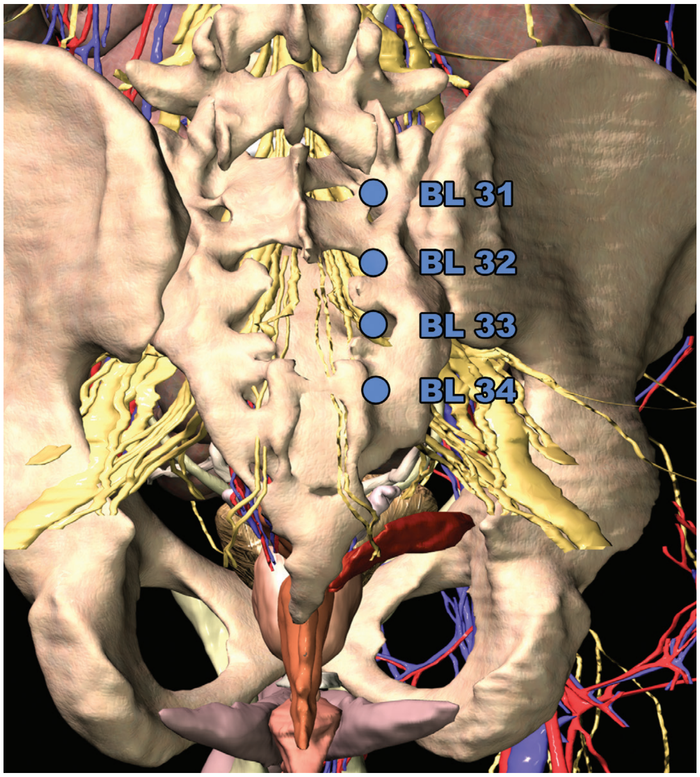

Figure 7-65. The four dorsal sacral foramina on each side of the sacrum (that transmit dorsal sacral spinal nerves) form the "upper", "second", "central", and "lower" "bone holes" pertaining to BL 31, BL 32, BL 33, and BL 34, respectively. Together, all eight foramina, or "bone holes" are called "Baliao", or "eight holes" beneficial for various urinary and reproductive disorders in conjunction with tibial nerve stimulation.[9]

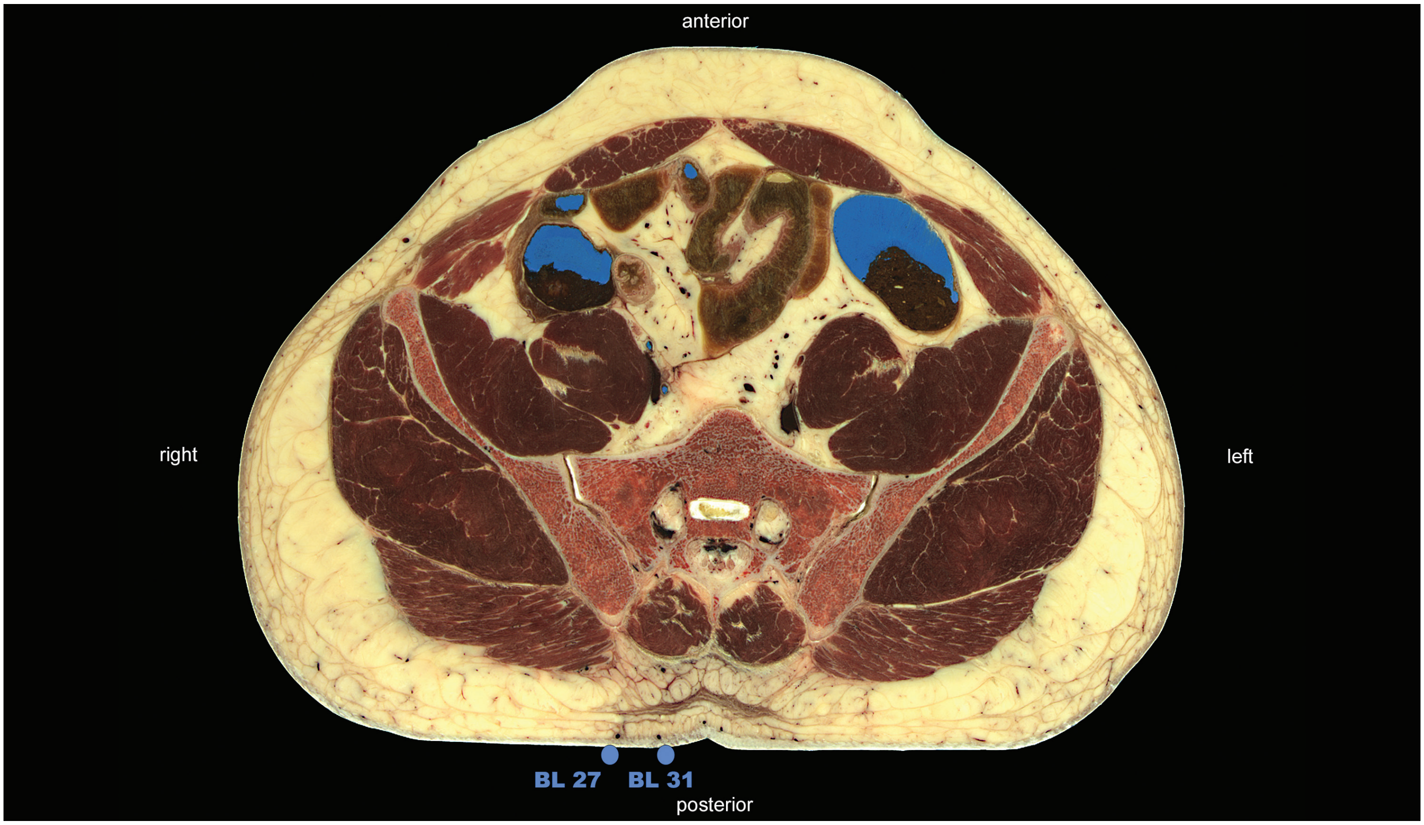

Figure 7-66. BL 31 lies medial to BL 27, over the first sacral foramen, the "Upper Bone Hole". This cross-section highlights the differences between these two parallel segments of the BL channel that cover the sacrum. At this level, the lines course closer together and they move closer to the midline. In a counterintuitive fashion, BL 31-34 form the "inner" BL line in that they sit upon the erector spinae group while BL 27-30 assemble along the lateral border.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and supporting tissue recovery.

Indications and Potential Point Combinations

- **Local back and hip pain and biomechanical dysfunction:** BL 31, local trigger points, BL 23, BL 40, GB 30, BL 54.
- **Gynecologic disorders:** irregular menses, uterine prolapse, leucorrhea: BL 31, BL 32, GV 4, SP 6.
- **Voiding dysfunction; urinary or fecal incontinence or retention:** BL 31, BL 32, BL 33, KI 3, SP 6.
- **Prostatitis:** BL 31, BL 30, BL 34, GV 2.
- **Erectile dysfunction:** BL 31, BL 32, BL 33, BL 34, CV 4.
- **Lumbar intervertebral disk disease:** BL 23, BL 25, BL 31, BL 32, BL 33, BL 44, and BL 54.[8]

Evidence-Based Applications

- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[1]
- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain,** even at a 3 month follow-up.[2]

BL 32

Ci Liao "Second Bone Hole"

Over the 2nd dorsal sacral foramen,[13] approximately midway between the midline (GV) and BL 28. (Refer to Figure 7-68 for relative locations of BL 32 and BL 28.)

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[14,15]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[16] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.[17]

Muscles

- **Longissimus muscle:** The longissimus attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.

Clinical Relevance: Muscle shortening in the erector spinae group, including the longissimus, accentuates tension affecting its tendinous attachment on the sacrum. This can cause low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines.

Nerves

- **Middle cluneal nerves (S1-S3):** Supply the skin of the gluteal region. After the nerves exit their respective foramina, they traverse the erector spinae and overlying fascia to enter subcutaneous tissue superficial to the gluteus maximus muscle. The more cranial branches of the middle cluneal nerves often communicate with the medial superior cluneal nerve.[18]
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S2 spinal nerve:** Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S2 contributes to the pudendal nerve (along with S3 and S4), which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. S2 also provides input to the sciatic nerve (L4-S3), the inferior gluteal nerve (see below), the nerve to the piriformis (S1,S2), the nerve to the obturator internus and the superior gemellus (L5-S2), the posterior femoral cutaneous nerve (S2,S3), and the perforating cutaneous nerve (S2,S3).

Clinical Relevance: Nerve entrapments in this region can produce pain that patients interpret as either of musculoskeletal or pelvic organ origin. Usually, freeing the nerve requires a multiplicity of needling sites along with massage and/or laser therapy to return slack to the tissues compressing the nerves.

Neuromodulation for reproductive problems and voiding dysfunction implements points over the sacrum (BL 27-34) to influence organ function in the pelvis through somatovisceral reflexes. Abnormalities in these same organs may sensitize the dorsal sacral spinal nerves, causing tenderness to palpation.

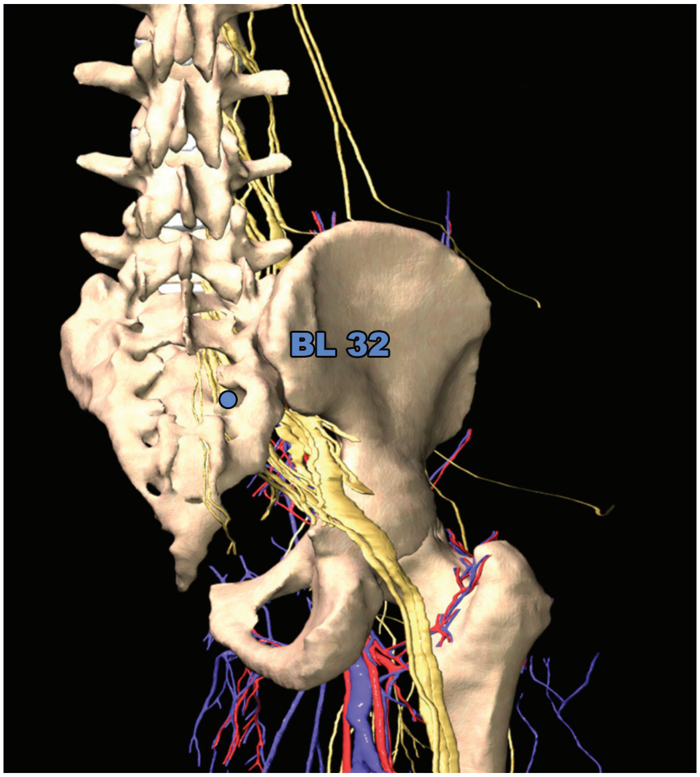

Figure 7-67. BL 32, over the "Second Bone Hole", or 2nd sacral foramen, influences several pelvic organ-related activities, including micturition, reproduction-related conditions, and defecation by dint of its association with the S2 spinal nerve and sacral spinal cord segments. The posterior superior iliac spine (PSIS) provide reliable topographical landmark by which to identify the S2 spinous process in most adult humans.[22]

Figure 7-68. Note the relationship between BL 32 and the 2nd dorsal sacral foramen and nerve root, the neuroanatomic target that engenders reflexes with nerves controlling reproductive and voiding activities. Furthermore, this cross section allows us to appreciate the size of the sacroiliac joint; the distinctive layers of the gluteus minimus, medius, and maximus; and the mass of the iliopsoas muscle ventral to the wings of the ilia.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and supporting tissue recovery.

Indications and Potential Point Combinations

- **Genitourinary disorders, including prostatitis, erectile dysfunction, urinary retention/detrusor hyperreflexia[19] or incontinence, voiding dysfunction:** BL 32, BL 23, BL 28, CV 2, CV 3, SP 6, KI 3.
- **Low back pain:** BL 32, appropriate trigger points and spinal segmental nerve supply.
- **Pelvic limb weakness and pain:** BL 32, BL 23, BL 40, Bafeng (web spaces between the toes), other points related to cause of myofascial pain or neurologic weakness.
- **Hip problems and restriction:** BL 32, BL 28, BL 54, GB 29, GB 30.
- **Uterine discomfort or dysfunction:[20,21]** BL 32, SP 6, GV 2, GV 3, KI 3.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis**.[1]
- Electroacupuncture at CV 3, CV 4, and BL 32 benefited patients with **spinal cord injuries** by shortening the time to achieve a balanced bladder, as long as the treatments occurred within three weeks after injury.[2]
- Neuroanatomically, acupuncture at BL 32 may support **sexual performance** through its influence on the pelvic nerve and inferior hypogastric ganglion.[3]
- Electroacupuncture at CV 1, CV 2, CV 4, CV 5, BL 21, BL 23, and BL 32 benefited patients with **persistent sensory urgency after transurethral resection of the prostate**.[4]
- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[5]
- Acupuncture at CV 3, CV 6, GV 4, BL 23, BL 32, LI 4, ST 36, and KI 3 served to neuromodulate recto-anal function in women with **fecal incontinence**.[6]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction**.[7]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in **improvement in sperm quality**, specifically in the ultrastructural integrity of spermatozoa.[8]

- Acupuncture at BL 15, BL 23, BL 32, GV 20, HT 7, PC 6, LR 3, SP 6, and SP 9 significantly improved **postmenopausal hot flushes and sweating episodes**.[9]
- Acupuncture at BL 32, TH 6, and ST 36 improved constipation due to **diabetes mellitus** in a report on a series of cases.[10]
- Acupuncture at BL 23, BL 24, BL 32, BL 39, and BL 54 offered improvement in five out of six urodynamic measures assessed in patients with **diabetic bladder dysfunction.**[11]
- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain**, even at a 3 month follow-up.[12]

BL 33

Zhang Liao "Central Bone Hole"

Over the 3rd dorsal sacral foramen, approximately midway between the midline (GV) and BL 29.

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[3,4]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

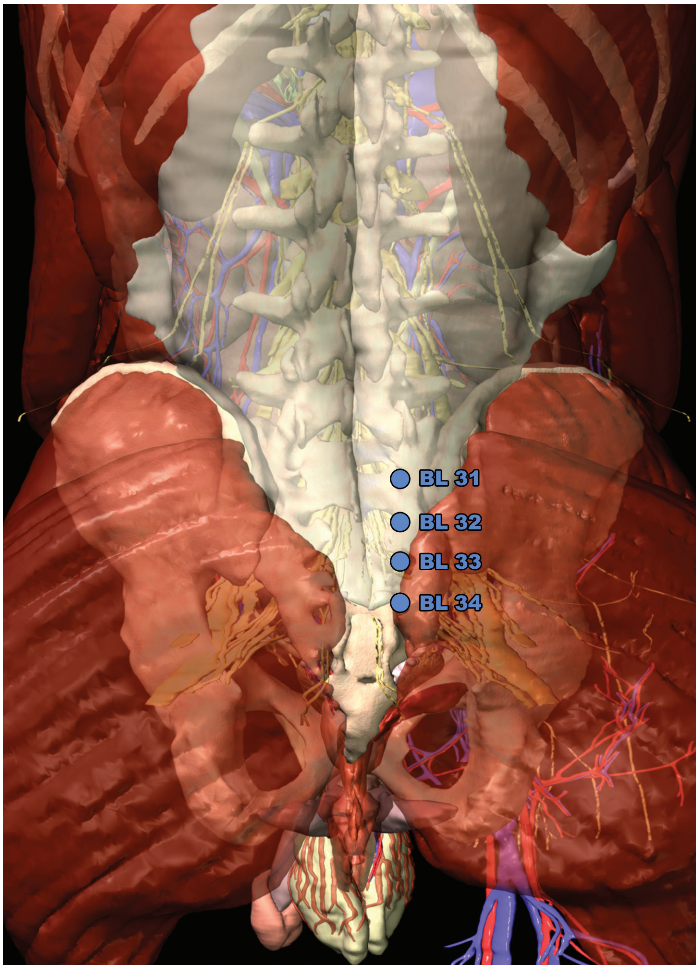

Figure 7-69. This image reveals the relationship between the "Bone Hole" points (BL 31 through BL 34) and the massive gluteus maximus muscle. BL 33, the "Central Bone Hole" receives its name for its location roughly at the midpoint of the sacrum. Muscles outside the sacrum can refer pain to this central bony structure, including the gluteus medius and maximus, the rectus abdominis, obturator internus, quadratus lumborum, sphincter ani, levator ani, and coccygeus.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[5] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.[6]

Muscles

- **Longissimus muscle:** The longissimus attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.
- **Gluteus maximus muscle:** Extends thigh and assists in lateral rotation.

Clinical Relevance: Muscle shortening in the erector spinae group, including the longissimus, accentuates tension affecting its tendinous attachment on the sacrum. This can cause low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines.

Trigger points in the gluteus maximus, i.e., at BL 33, cause pain to refer along the sacroiliac junction, to the intergluteal cleft, and then around the horizontal gluteal crease and proximal caudal thigh. In acupuncture terminology, BL 33 refers pain craniad to BL 26, caudomediad to BL 35, laterad to BL 36 and GB 29, and distad to BL 37.

Nerves

- **Middle cluneal nerves (S1-S3):** Supply the skin of the gluteal region. After the nerves exit their respective foramina, they traverse the erector spinae and overlying fascia to enter subcutaneous tissue superficial to the gluteus maximus muscle. The more cranial branches of the middle cluneal nerves often communicate with the medial superior cluneal nerve.[7]
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S3 spinal nerve:** Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S3 contributes to the pudendal nerve (along with S2 and S4), which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter. S3 also supplies the sciatic nerve (L4-S3), the nerves to the levator ani and coccygeus muscles (S3,S4), the posterior femoral cutaneous nerve (S2,S3), and the perforating cutaneous nerve (S2,S3).

Clinical Relevance: Nerve entrapments in this region can produce pain that patients interpret as either of musculoskeletal

Figure 7-70A. This image reveals the way in which a needle entering BL 33 might first encounter the gluteus maximus, then the tough thoracolumbar fascia, and finally the tail of the longissimus muscle, depending on its angle of insertion and final depth. Too, this cross-section depicts the way in which the piriformis muscle could entrap the sciatic nerve against the greater sciatic notch, in cases of myofascial dysfunction.

or pelvic organ origin. Usually, freeing the nerve requires a multiplicity of needling sites along with massage and/or laser therapy to return slack to the tissues compressing the nerves.

Neuromodulation for reproductive problems and voiding dysfunction implements points over the sacrum (BL 27-34) to influence organ function in the pelvis through somatovisceral reflexes. Abnormalities in these same organs may sensitize the dorsal sacral spinal nerves, causing tenderness to palpation.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and supporting tissue recovery.

Indications and Potential Point Combinations

- **Genitourinary disorders, including prostatitis, erectile dysfunction, urinary retention or incontinence, voiding dysfunction:** BL 33, BL 32, BL 23, BL 28, CV 2, CV 3, SP 6, KI 3.

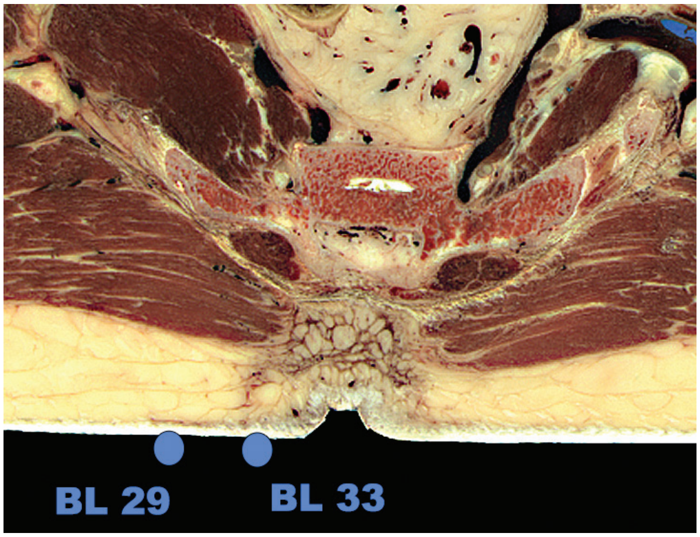

Figure 7-70B. Visualizing the layered anatomy beneath a point allows one to connect the palpatory feedback delivered through the needle as the tip meets each new layer and tissue type.

- **Hemorrhoids:** BL 33, BL 29, BL 30, BL 35, GV 1.
- **Low back pain:** BL 33, BL 32, appropriate trigger points and spinal segmental nerve supply.
- **Local and radiating pain, sciatica:** BL 33, BL 29, BL 30, BL 54, BL 40, BL 60, KI 3, GB 30.
- **Pelvic limb weakness and pain:** BL 33, BL 32, BL 23, BL 40, Bafeng (web spaces between the toes), other points related to cause of myofascial pain or neurologic weakness.
- **Hip problems and restriction:** BL 33, BL 32, BL 28, BL 54, GB 29, GB 30.

Evidence-Based Applications

- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[1]
- Following a series of acupuncture treatments, men with **poor quality sperm** experienced a significant increase in fertility index, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. Twelve acupuncture points from the following group were selected according to patient presentation: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[2]
- Needling BL 33 to the sacral periosteum over the 3rd dorsal sacral foramen and stimulating manually for 20 minutes led to a statistically significant improvement in symptoms and quality of life for men clinically diagnosed with chronic **prostatitis/chronic pelvic pain syndrome** (CP/CPPS).[8]
- Acupuncture with manual needle rotation at BL 33 for 10 minutes improved nocturnal bladder capacity and reduced episodes of occurrence in patients with mono-symptomatic **nocturnal enuresis.**[9]
- Acupuncture at BL 33 significantly reduced pain and intrapelvic venous congestion in male patients with **chronic pelvic pain.**[10]

BL 34

Xia Liao "Lower Bone Hole"

Over the 4th dorsal sacral foramen, approximately midway between the midline (GV) and BL 30.

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure whose fibers crisscross the sacrum.

Clinical Relevance: The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine.[1,2]

Tension in the fasciae of the back, including the thoracolumbar fascia and the vertebral aponeurosis, increases as a result of muscular contraction from the abdominal wall, the erector spinae, and the gluteal muscles. Fascial tension transmits forces away from the spine and onto the ilium and pelvic limb. This funneling of load helps to protect the sacroiliac joint.

Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[3] Some patients with chronic low back pain exhibit reduced thoracolumbar shear strain or shear plane motion that possibly results from abnormal movement patterns of the trunk or intrinsic connective tissue pathology.[4]

Muscles

- **Longissimus muscle:** The longissimus attaches to the median sacral crest, to the spinous processes of the lumbar and last two thoracic vertebrae, and the supraspinal ligament. Some of its fibers are continuous with the fibers of origin of the gluteus maximus.
- **Gluteus maximus muscle:** Extends thigh and assists in lateral rotation.

Clinical Relevance: Muscle shortening in the erector spinae group, including the longissimus, accentuates tension affecting its tendinous attachment on the sacrum. This can cause low back or sacroiliac pain. Acupuncture, massage therapy, and laser treatment of the back should attend to the entire length of the erector spinae group. Trigger points in the thoracolumbar regions of the iliocostalis lumborum and longissimus thoracis send pain to the buttocks along the BL channel, both inner and outer lines.

Trigger points in the gluteus maximus, i.e., at BL 33, cause pain to refer along the sacroiliac junction, to the intergluteal cleft, and then around the horizontal gluteal crease and proximal caudal thigh. In acupuncture terminology, BL 33 refers pain craniad to BL 26, caudomediad to BL 35, laterad to BL 36 and GB 29, and distad to BL 37.

Nerves

- **Middle cluneal nerves (S1-S3):** Supply the skin of the gluteal region. After the nerves exit their respective foramina, they traverse the erector spinae and overlying fascia to enter subcutaneous tissue superficial to the gluteus maximus muscle. The more cranial branches of the middle cluneal nerves often communicate with the medial superior cluneal nerve.[5]
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **S4 spinal nerve:** Carries a portion of the sacral parasympathetic outflow (S2-S4) to the pelvic viscera via the sacral spinal nerves, otherwise known as the pelvic (or parasympathetic) splanchnic nerves. S4 contributes to the pudendal nerve (S2-S4),[6] which is the chief sensory nerve to the external genitalia and supplies muscular branches to the perineal muscles, the external urethral sphincter, and the external anal sphincter.

S4 also supplies fibers to the nerves to the levator ani and coccygeus (S3,S4). S4 contributes to the coccygeal plexus, which gives rise to the anococcygeal nerve that penetrates the sacrotuberous ligament and innervates the skin in the region of the anus and coccyx.

- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: Nerve entrapments in this region can produce pain that patients interpret as either of musculoskeletal or pelvic organ origin. Usually, freeing the nerve requires a multiplicity of needling sites along with massage and/or laser therapy to return slack to the tissues compressing the nerves.

Neuromodulation for reproductive problems and voiding dysfunction implements points over the sacrum (BL 27-34) to influence organ function in the pelvis through somatovisceral

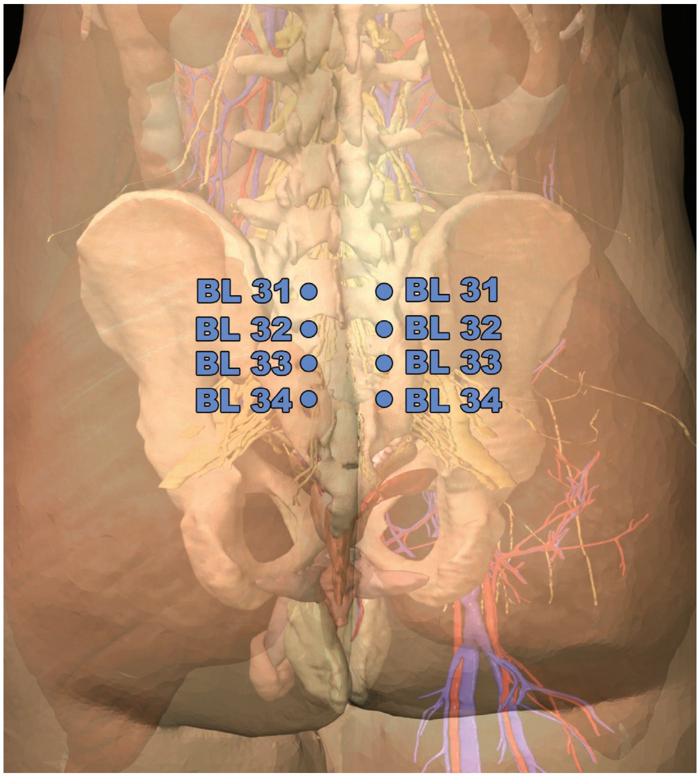

Figure 7-71. BL 34 ("Lower Bone Hole"), corresponds to S4. BL 33 ("Central Bone Hole") belongs to S3; BL 32 ("Second Bone Hole") to S2, and BL 31 ("Upper Bone Hole") to S1.

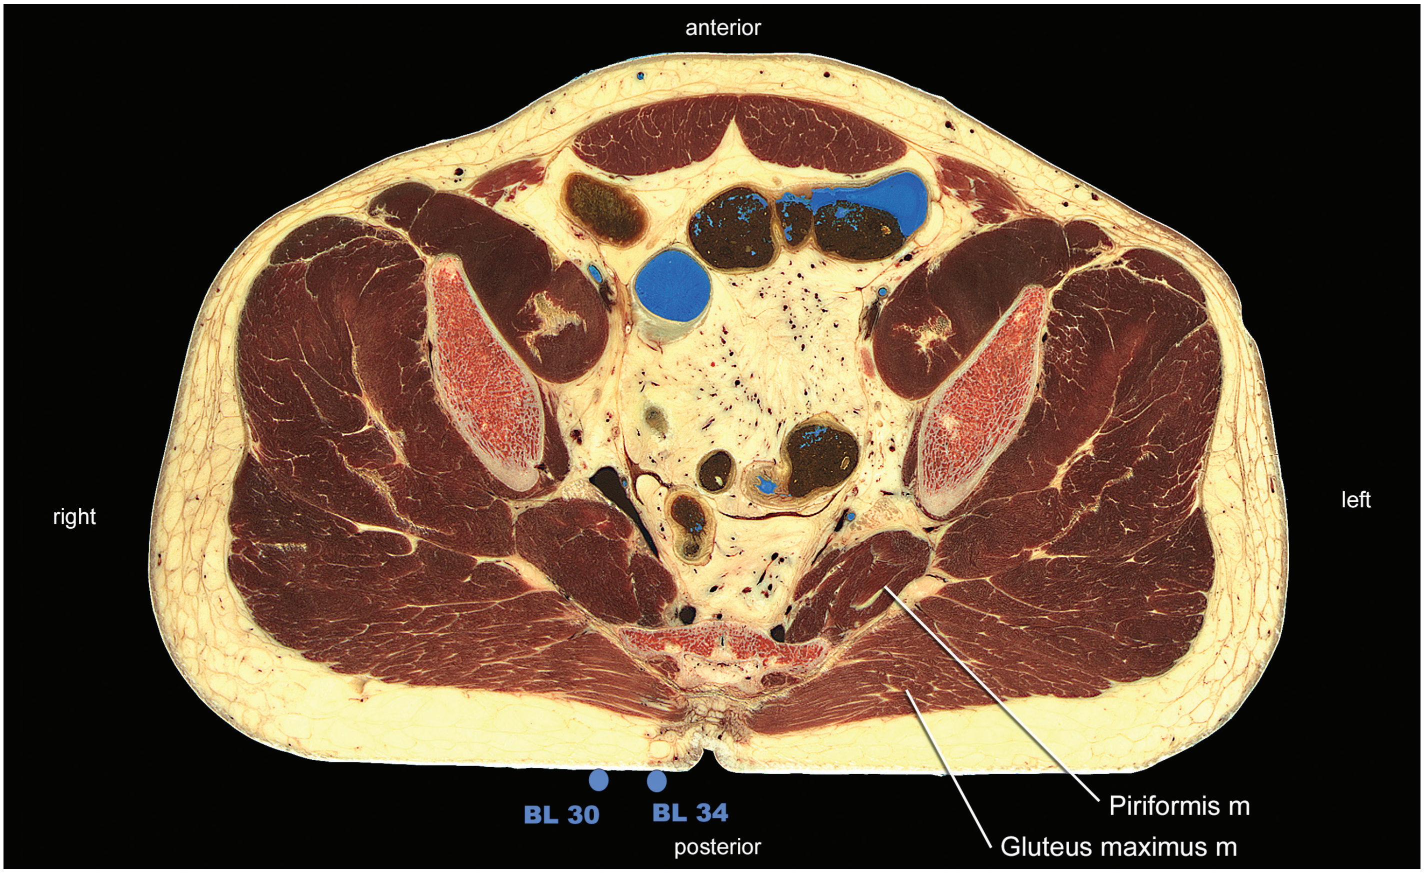

Figure 7-72. In this cross section, the pelvis is merging with the pelvic limbs, showing fewer organs and more skeletal muscle.

reflexes. Abnormalities in these same organs may sensitize the dorsal sacral spinal nerves, causing tenderness to palpation.

Vessels

- **Lateral sacral artery:** Supplies the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.
- **Lateral sacral vein:** Drains the piriformis, the structures in the sacral canal, the erector spinae muscles, and the overlying skin.

Clinical Relevance: Improving circulation to the local tissues through acupuncture, massage, and laser therapy assists in resolving myofascial dysfunction and supporting tissue recovery.

Hui Yang "Meeting of Yang"

Below the sacrum, 0.5 cun lateral to the midline, level with the tip of the coccyx.

Ligaments

- **Sacrotuberous ligament:** Provides support and resiliency to the sacroiliac region. Attaches from the dorsal iliac crest, caudal three sacral vertebrae, and coccyx to the medial aspect of the ischial tuberosity.[3] The ligament associates intimately with several ligamentous and muscular structures in the region, as well as a portion of the long head of the biceps femoris muscle.[4]

Clinical Relevance: The pudendal nerve can experience entrapment by the sacrotuberous ligament, causing patients to complain of pain along the course of this nerve. Ossification of the ligament elevates the risk of pudendal nerve entrapment. Pregnancy can cause women to develop strain symptoms in the lumbosacral region and pelvis in the eighth month as well as after parturition.[5] While the most frequently irritated ligaments include the interspinous, iliolumbar, and sacroiliac, the sacrotuberous become strained during pregnancy and cause pelvic pain.

Muscles

- **Gluteus maximus muscle:** Extends the thigh and assists in lateral rotation.

Clinical Relevance: Trigger points in the gluteus maximus, i.e., at BL 35, send pain mediad to the intergluteal crease and anorectal region. Pain in the vicinity of BL 35 can arise from trigger point pathology in the sphincter ani, levator ani, coccygeus, and obturator internus muscles.

Nerves

- **Middle cluneal nerve (S1-S3):** Supplies the skin of the gluteal region.
- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.
- **Anococcygeal nerves (S4, S5):** From the coccygeal plexus, the anococcygeal nerves emerge through the sacrotuberous ligament to supply a small region of skin close to the coccyx.
- **Ganglion impar:** The only unpaired, autonomic ganglion in the body, marking the end of the sympathetic chain. It represents the pelvic portion of the sympathetic trunk, situated ventral to the sacrum and medial to the ventral sacral foramina. It consists of four to five, small, sacral sympathetic ganglia that connect by means of interganglionic cords. The ganglion impar is located about level with the coccyx but may occur anywhere from 10mm to 30 mm ventral to it. In conjunction with the local somatic nerves and the ganglion impar, BL 35 represents a somatosympa-

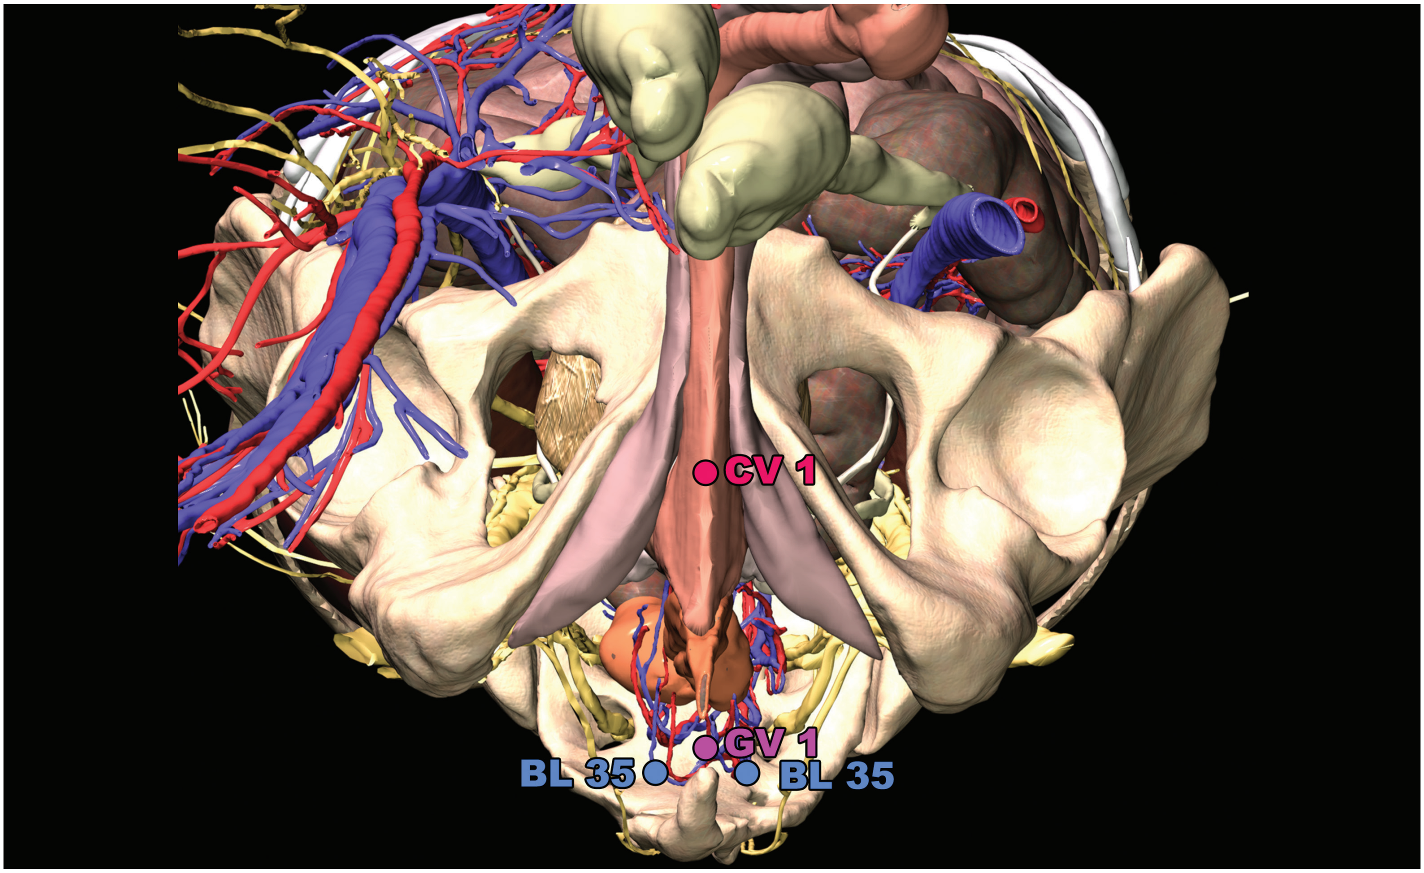

Figure 7-73A. BL 35, "Meeting of Yang", indicates the location near the coccyx where the BL channel greets the GV line just below the tip of the coccyx at GV 1. "Meeting of Yang" may metaphorically suggest the ganglion impar, representing the site at which the the sympathetic chain ganglia join together. This view of the anorectal region (at bottom of image) exposes the ventral spinal nerve rami and local vasculature.

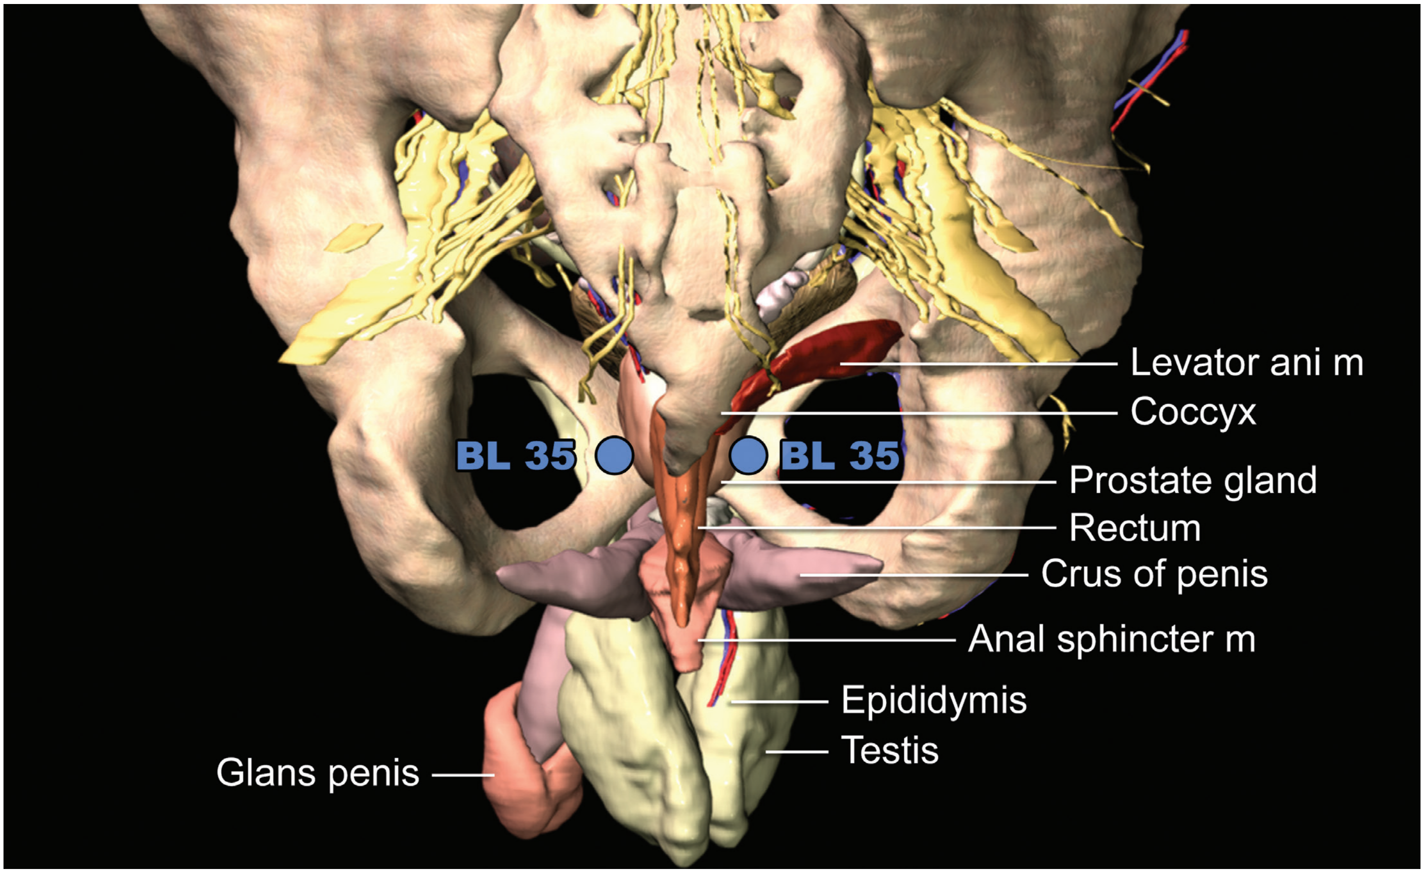

Figure 7-73B. The nerves that supply BL 35 reflex through sacral segments and sympathetic ganglia that also innervate the local viscera, shown here.

thetic convergence site and multifaceted treatment opportunity.

Clinical Relevance: Anesthetic blockade or radiofrequency ablation of the ganglion impar has been used to treat chronic neuropathic pelvic or perineal pain due to nonmalignancy-associated etiologies. Problems treated include coccydynia;[6] sacral postherpetic neuralgia; spinal cord malformations; failed back surgery; visceral disease in the distal rectum, anus, distal urethra, vulva, or distal third of the vagina; and perineal hyperhidrosis. Perineal pain from cancer metastasized to the perineum (from the cervix, prostate, testicles, colon, or rectum), postsurgical thrombosis of perineal veins, vaginal prolapse or protrusion, and testicular ablation may also respond to ganglion impar blocks. A less invasive approach with acupuncture and related techniques offers an alternative to nerve blocks and radiofrequency ablation.

Vessels

- **Inferior gluteal artery:** Supplies the pelvic diaphragm (which includes the coccygeus and levator ani muscles), the piriformis, quadratus femoris, proximal hamstring, and gluteus maximus muscles as well as the sciatic nerve.
- **Inferior gluteal vein:** Drains blood from the gluteal region.

Clinical Relevance: Impaired circulation to BL 35 perpetuates myofascial dysfunction. Medical acupuncture and related techniques improve blood flow and venous drainage, benefiting tissue health.

Indications and Potential Point Combinations

- **Sacral, coccygeal, and lumbar pain:** BL 35, BL 31, BL 32, BL 25, local tender points.
- **Rectal, prostate, and anal problems:** BL 35, BL 34, GV 1.
- **Voiding dysfunction:**[7] BL 35, BL 32, BL 39, GV 2, SP 6.

Evidence-Based Applications

- A case series showed that acupuncture of BL 23 and BL 35 benefited men suffering from **chronic prostatitis.**[1]
- Acupuncture at BL 23 and BL 35 outperformed acupuncture at CV 3, CV 4, SP 6, and SP 9 in treating **chronic prostatitis**, possibly because of the influence of BL 35 on the pelvic nerve plexus.[2]

Figure 7-74. From superficial to deep, the nerves impacted by BL 35 include the middle cluneal, inferior gluteal, pelvic nerve, and branches of the pudendal nerve.[8] These nerves influence reproductive organ function, control over micturition and defecation, and pelvic pain. By treating local trigger points, acupuncture and related techniques address levator ani syndrome, coccygodynia, and proctalgia fugax.[9]

BL 36

Cheng Fu "Hold and Support"

On the gluteal region, just below the buttock, on a line directly cranial to BL 40. In the center of the transverse gluteal fold, in a depression between the biceps femoris and the semitendinosus muscles.

Muscles

- **Gluteus maximus muscle, inferior margin:** Extends thigh and assists in lateral rotation.
- **Biceps femoris muscle (long head, tendon or musculotendinous junction):** Flexes the leg and rotates it laterally when the knee is flexed. Extends the thigh when initiating ambulation.
- **Semitendinosus muscle:** Extends the thigh. Flexes the leg and rotates it medially when knee flexes. When both the thigh and leg flex, the semitendinosus, with the semimembranosus, extend the trunk.

Clinical Relevance: Myofascial dysfunction in the gluteus maximus at BL 36 refers pain to the horizontal gluteal fold, the caudal sacrum and coccygeal region, and the hip, as well as diffusely across the entire ipsilateral buttock.

Trigger points in the semimembranosus and semitendinosus muscles refer pain strongly to the proximal thigh and BL 36. Thus, palpation of the pelvic region, including the thigh assist in revealing the fuller picture regarding sources of trigger points pathology.

Nerves

- **Inferior cluneal nerve (S2-S3):** Supplies skin of buttock or gluteal region. Arises from the posterior femoral cutaneous nerve, which sends a perineal branch to the perineum.[3]
- **Posterior femoral cutaneous nerve (S1-S3):** Sends cutaneous branches to the buttock and the posterior and uppermost medial thigh surfaces.
- **Sciatic nerve (L4-S3):** Supplies no structures in the gluteal region, but does supply all of the leg and foot muscles, as well as the skin of the posterior thigh, most of the leg, and the skin of the foot. It comprises the tibial and common fibular (or common peroneal) nerves.

Clinical Relevance: Each of the nerves supplying BL 36 can suffer entrapment or impingement from structures compressing or otherwise irritating the nerve. For example, Figure 7-75 describes, visually, how certain muscles, especially the piriformis, may compress the sciatic and posterior femoral cutaneous nerves as they exit the pelvis. Entrapment of a perineal branch of the inferior cluneal nerve can cause neuropathic pain in the perineum, in addition to pudendal neuropathy. In that the inferior cluneal nerve branches off of the posterior femoral cutaneous nerve, neuromodulation of the latter at GB 30 and BL 36 may aid in resolving the pain, as well as funding the course of myofascial dysfunction compressing the nerve.

Neuromodulation of the posterior femoral cutaneous nerve may assist in treating micturition disorders such as overactive bladder and urinary incontinence by dint of its ability to inhibit the micturition reflex through somatic afferent activation.[4]

Vessels

- **Inferior gluteal artery:** Supplies the pelvic diaphragm (which includes the coccygeus and levator ani muscles), the piriformis, quadratus femoris, proximal hamstring, and gluteus maximus muscles as well as the sciatic nerve.
- **Inferior gluteal vein:** Drains blood from the gluteal region.

Clinical Relevance: Impaired circulation to BL 36 perpetuates myofascial dysfunction. Medical acupuncture and related techniques improve blood flow and venous drainage, benefiting tissue health.

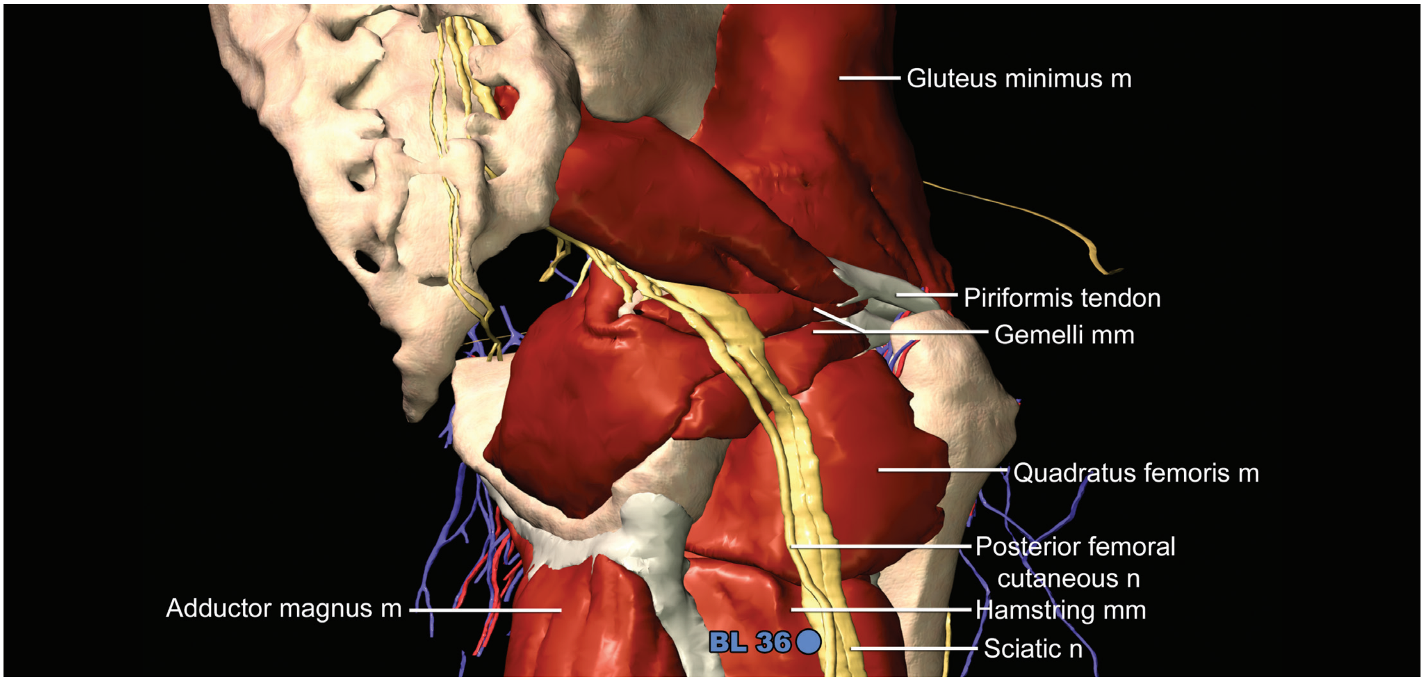

Figure 7-75. As shown here, tension held in various muscles near BL 36 may aggravate the sciatic nerve and precipitate "sciatica", exemplified by its characteristic pain radiating from the back or hip to the lower leg or foot. Although distal needling at BL 36, BL 37, BL 40, and GB 34 can help, one Chinese study indicated that the most robust and rapid benefits result from proximal needling at GB 30.[6]

Indications and Potential Point Combinations

- **Lumbar pain radiating into hips or thighs:** BL 36, BL 37, BL 40, BL 23, BL 25, other tender myofascial trigger points.
- **Hamstring strain:** BL 36, BL 37, BL 40, deactivate trigger points responsible for myofascial compression.[5]

Evidence-Based Applications

- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[1]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[2]

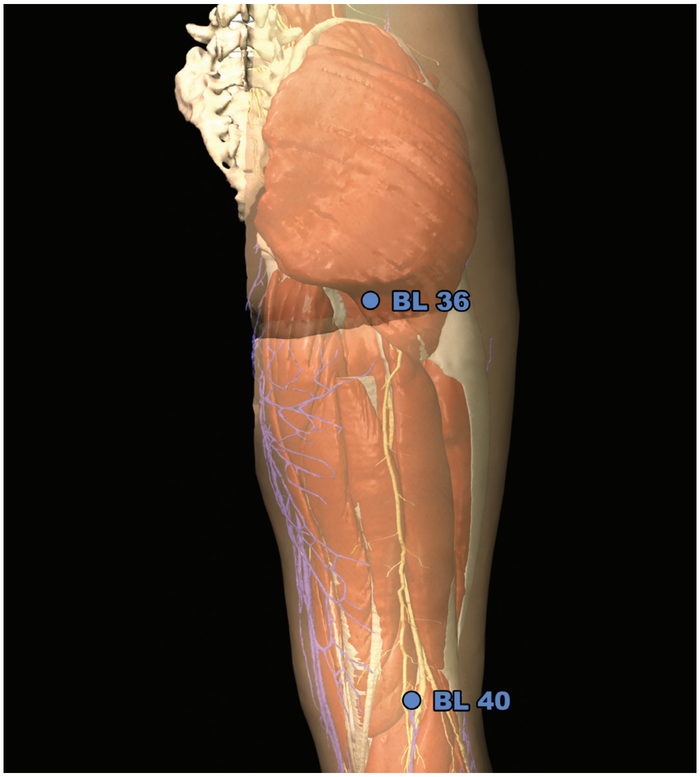

Figure 7-76. Known as "Hold and Support", BL 36 exists near structures that help hold the body upright and standing; i.e., the sciatic nerve, the hamstring muscles, the gluteus maximus, and the pelvis itself. Finding BL 36 should not pose too much difficulty, as it lies in the middle of the gluteal crease in line with BL 40 at the center of the popliteal fossa.

Figure 7-77. The distance between the sciatic nerve and BL 36 will depend on the muscularity and adiposity of a patient., but one should remember its presence beneath BL 36 to avoid damaging the nerve with incautious insertion.

BL 37

Yin Men "Gate of Abundance" or "Center of Abundance"

On the posterior thigh, in a depression between the biceps femoris and semitendinosus muscles, 6 cun distal to BL 36 or 8 cun proximal to BL 40, on the line connecting BL 36 to BL 40.

Muscles

- **Biceps femoris muscle:** Flexes the leg and rotates it laterally when the knee is flexed. Extends the thigh when initiating ambulation.
- **Semitendinosus and semimembranosus muscles (medial hamstrings):** Hip extensors and knee flexors when the thigh and leg are freely moveable (i.e., not "fixed" in one location). The medial hamstrings assist with medial hip rotation.

Clinical Relevance: While local hamstring trigger points refer pain to the caudal thigh that extends from the transverse gluteal crease to the popliteal region, pain at BL 37 may be referred from the gluteus minimus as well. Trigger points in the posterior portion of the gluteus minimus send pain toward the coccyx (BL 35) and the back of the thigh and leg (from BL 36 to BL 56).

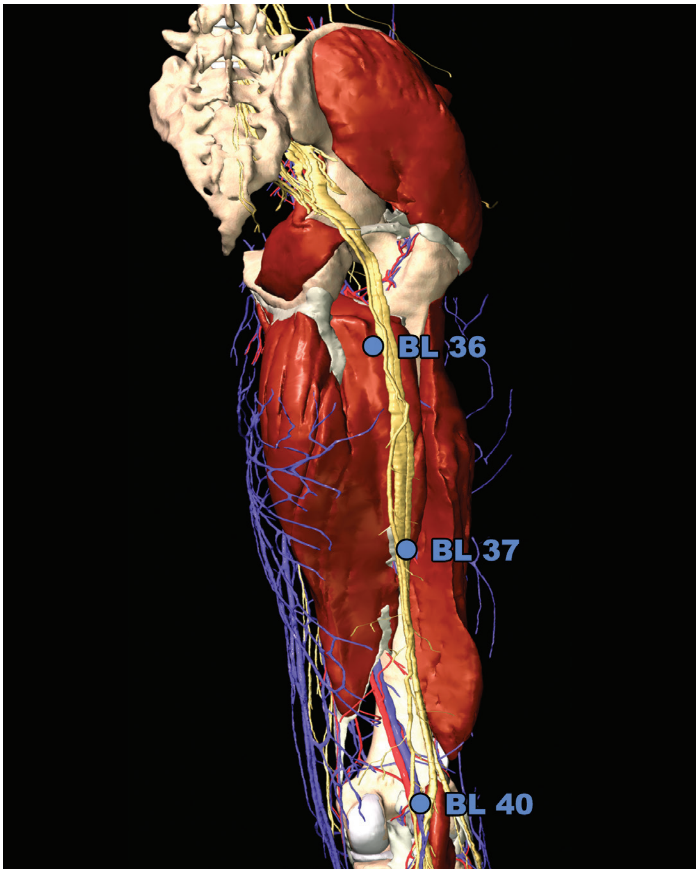

Figure 7-78. This "Gate of Abundance", BL 37, lands where the hamstring muscles separate into lateral and medial bundles. This point has been used since ancient times in China and Tibet for sciatic neuropathy.[4] Its alternate name, "Center of Abundance" connotes the central placement of BL 37 on the caudal thigh, amid the massive muscle (or other fleshy tissue) found there.

Nerves

- **Posterior femoral cutaneous nerve (S1-S3):** Sends cutaneous branches to the buttock and the posterior and uppermost medial thigh surfaces.
- **Sciatic nerve (L4-S3):** Innervates the hamstring muscles, all of the leg and foot muscles, as well as the skin of the posterior thigh, most of the leg, and the skin of the foot. It comprises the tibial and common fibular (or common peroneal) nerves.

Clinical Relevance: Neuromodulation of the posterior femoral cutaneous nerve may assist in treating micturition disorders such as overactive bladder and urinary incontinence by dint of its ability to inhibit the micturition reflex through somatic afferent activation.[2]

Neuromodulation of the sciatic nerve is helpful for a variety of conditions caused by sciatic nerve damage, including piriformis syndrome, total hip arthroplasty, injury of the vasa nervorum to the sciatic, and trauma. One should consider neuromodulation of the spinal nerve roots contributing to the sciatic (L4-S3), the axon itself (GB 30 to BL 37), and its branches (common fibular and tibial), on down to the digital nerves of the foot.

Vessels

- **Profunda femoris artery:** This is the principal arterial supply to the adductor, extensor, and flexor muscles of the thigh.

The profunda femoris artery also gives rise to the lateral and medial circumflex femoral arteries, the perforating arteries and numerous muscular branches.

- **Profunda femoris vein:** Drains the regions supplied by the muscular and perforating branches of the profunda femoris artery and thereby establishes communications with the popliteal vein or superficial femoral vein below and the inferior gluteal vein. It may also drain the medial and lateral circumflex femoral veins.

Clinical Relevance: Electroacupuncture stimulation of BL 35 and other sites that affect the pudendal nerve may significantly increase blood flow to the sciatic nerve without increasing heart rate or systemic blood pressure.[3] Thus, treating patients for sciatic neuropathy may warrant including somatic afferent stimulation to the pudendal nerve in order to neuromodulate the vasa nervorum of the sciatic nerve.

Indications and Potential Point Combinations

- **Lumbar pain radiating to hips and thighs, thigh pain or swelling, inability to ambulate or bear weight, other problems relating to the sciatic nerve, including pain, weakness, numbness:** BL 37, BL 36, BL 25, BL 23, GV 4, ST 36, tender myofascial trigger points, BL line points related to somatic dysfunction and/or spinal cord injury. Consider Bafeng points at web spaces between the toes for paresis or paralysis.

Evidence-Based Applications

- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain**

BL 38

Fu Xi “Superficial Cleft”

Proximal to the popliteal region, 1 cun proximal to BL 39, on the medial side of the tendon of the biceps femoris muscle. Find with the knee slightly flexed.

Muscles

- **Biceps femoris muscle:** Flexes the leg and rotates it laterally when the knee is flexed. Extends the thigh when initiating ambulation.
- **Plantaris muscle:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.

Clinical Relevance: While local hamstring trigger points refer pain to the caudal thigh that extends from the transverse gluteal crease to the popliteal region, pain at BL 37 may be referred from the gluteus minimus as well. Trigger points in the posterior portion of the gluteus minimus send pain toward the coccyx (BL 35) and the back of the thigh and leg (from BL 36 to BL 56). Trigger point pathology in the biceps femoris at BL 37 can refer pain to the popliteal region, encompassing BL 38, BL 39, and BL 40.

Treatment of BL 38 may also impact the attachment trigger point of the plantaris muscle near to where it attached onto the lateral supracondylar line of the femur. The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to “tennis leg”, a calf injury identified by a “snapping” in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[1] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

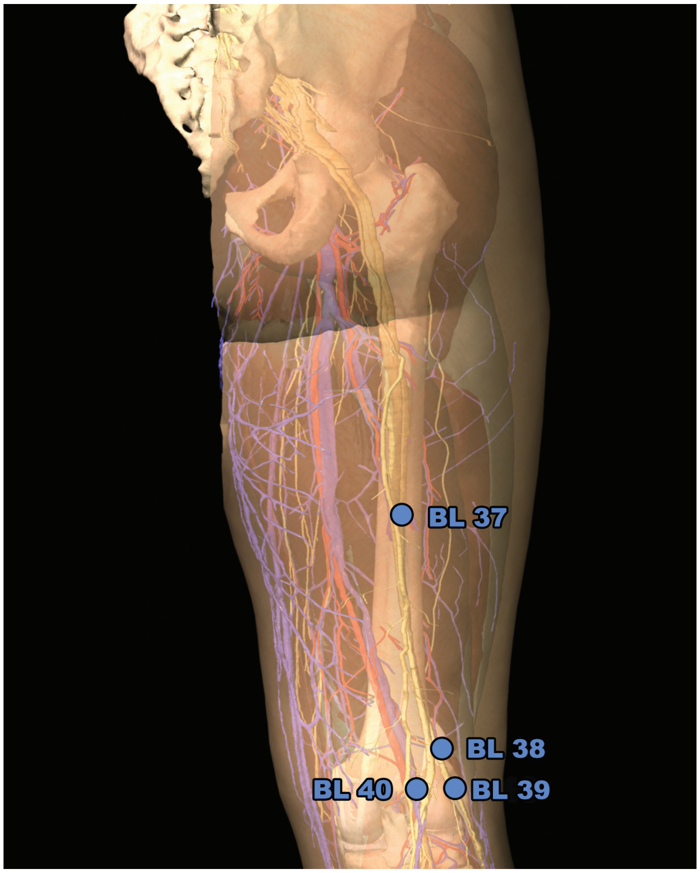

Figure 7-80. BL 38 falls in a depression formed by the biceps femoris muscle as it narrows into a tendon. Its name “Superficial Cleft” refers to this palpable valley as well as to the division of the sciatic nerve into the common fibular and tibial nerves.

Nerves

- **Posterior femoral cutaneous nerve (S1-S3):** Sends cutaneous branches to the buttock and the posterior and uppermost medial thigh surfaces.
- **Sciatic nerve (L4-S3):** Supplies no structures in the gluteal region, but does supply all of the leg and foot muscles, as well as the skin of the posterior thigh, most of the leg, and the skin of the foot. It comprises the tibial and common fibular (or common peroneal) nerves.
- **Tibial nerve (S1-S2):** Supplies the plantaris muscle with fibers arising from spinal segments S1 and S2.

Clinical Relevance: Neuromodulation of the posterior femoral cutaneous nerve may assist in treating micturition disorders such as overactive bladder and urinary incontinence by dint of its ability to inhibit the micturition reflex through somatic afferent activation.[2]

Neuromodulation of the sciatic nerve is helpful for a variety of conditions caused by sciatic nerve damage, including piriformis syndrome, total hip arthroplasty, injury of the vasa nervorum to the sciatic, and trauma. One should consider neuromodulation of the spinal nerve roots contributing to the sciatic (L4-S3), the axon itself (GB 30 to BL 37), and its branches (common fibular and tibial), on down to the digital nerves of the foot.

Vessels

- **Profunda femoris artery:** This is the principal arterial supply to the adductor, extensor, and flexor muscles of the thigh. The profunda femoris artery also gives rise to the lateral and medial circumflex femoral arteries, the perforating arteries and numerous muscular branches.
- **Profunda femoris vein:** Drains the regions supplied by the muscular and perforating branches of the profunda femoris artery and thereby establishes communications with the popliteal vein or superficial femoral vein below and the inferior gluteal vein. It may also drain the medial and lateral circumflex femoral veins.

Figure 7-81. In contrast to the heavy musculature housed at BL 37, "Central Abundance", this cross section at the level of BL 38 is dominated by structures that move and constitute the knee.

Clinical Relevance: Electroacupuncture stimulation of BL 35 and other sites that affect the pudendal nerve may significantly increase blood flow to the sciatic nerve without increasing heart rate or systemic blood pressure.[3] Thus, treating patients for sciatic neuropathy may warrant including somatic afferent stimulation to the pudendal nerve in order to neuromodulate the vasa nervorum of the sciatic nerve.

Indications and Potential Point Combinations

- **Lumbar pain radiating to hips and thighs, thigh pain or swelling, inability to ambulate or bear weight, other problems relating to the sciatic nerve, including pain, weakness, numbness:** BL 37, BL 36, BL 25, BL 23, GV 4, ST 36, tender myofascial trigger points, BL line points related to somatic dysfunction and/or spinal cord injury. Consider Bafeng points at web spaces between the toes for paresis or paralysis.

Sciatic nerve injury: GB 30, BL 36, BL 37, BL 38, ST 36.

BL 39

Wei Yang "Outside of the Crook" or "Bend Yang"

On the back of the knee, at the lateral limit of the popliteal crease, in a depression just medial to the tendon of the biceps femoris muscle.

Muscles

- **Biceps femoris muscle:** Flexes the leg and rotates it laterally when the knee is flexed. Extends the thigh when initiating ambulation.
- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended. Raises the heel during ambulation. Flexes the leg at the knee joint.
- **Plantaris muscle:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.

Clinical Relevance: While local hamstring trigger points refer pain to the caudal thigh that extends from the transverse gluteal crease to the popliteal region, pain at BL 37 may be referred from the gluteus minimus as well. Trigger points in the posterior portion of the gluteus minimus send pain toward the coccyx (BL 35) and the back of the thigh and leg (from BL 36 to BL 56). Trigger point pathology in the biceps femoris at BL 37 can refer pain to the popliteal region, encompassing BL 38, BL 39, and BL 40. Palpatory findings of intense pain at the distal biceps femoris should heighten suspicion of a myofascial trigger point.[2]

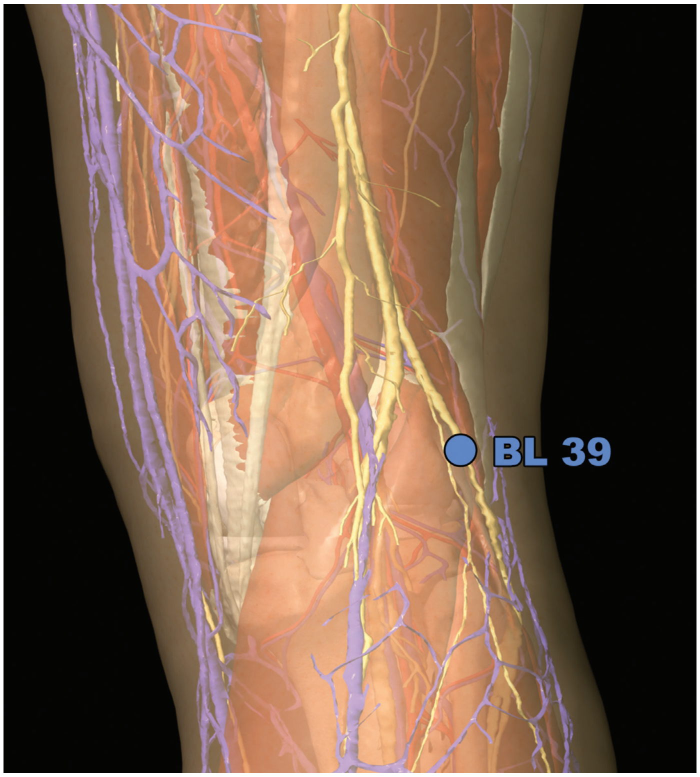

Figure 7-82. This caudomedial view of the right knee examines the location of BL 39 at the lateral extent of the popliteal fossa. Both of the point's descriptive titles, "Outside of the Crook" and "Bend Yang" indicate the placement of BL 39 at this lateral landmark. Consistent with the way in which the BL channel followed the sciatic nerve, now that the sciatic nerve separated (at BL 38), the lateral line joins at BL 39 with the common fibular while BL 40 takes the medial line with the tibial nerve.

The trigger point in the proximal, lateral head of the gastronemius muscle refers causes the sensation of pain in the lateral, distal popliteal fossa and proximal calf.

Treatment of BL 39 may also impact the attachment trigger point of the plantaris muscle near to where it attached onto the lateral supracondylar line of the femur. The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to "tennis leg", a calf injury identified by a "snapping" in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[3] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

Nerves

- **Posterior femoral cutaneous nerve (S1-S3):** Sends cutaneous branches to the buttock and the posterior and uppermost medial thigh surfaces.
- **Common fibular (peroneal) nerve (L4-S2) at origin of lateral sural cutaneous nerve:** The common fibular nerve branch (i.e., the lateral sural cutaneous nerve) supplies the skin on the lateral portion of the posterior aspect of the leg. The articular branch innervates the knee joint. The common fibular nerve divides into the superficial and deep fibular nerves. The superficial fibular nerve innervates the fibularis longus and brevis muscles, as well as the skin on the distal third of the anterior surface of the leg, and the dorsum of the foot. The deep fibular nerve innervates the anterior muscles of the leg and the dorsum of the foot, as well as the skin of the first interdigital cleft. The deep fibular nerve also innervates the joints it crosses with its articular branches.
- **Tibial nerve (S1-S2):** Supplies the plantaris muscle with fibers arising from spinal segments S1 and S2.

Clinical Relevance: After the common fibular nerve leaves the sciatic at BL 38, it courses laterad toward BL 39 in an exposed fibro-osseous tunnel toward the fibular neck and head to enter a fibular tunnel between the two heads of the peroneus longus muscle.[4] This location represents only the beginning of several sites of nerve entrapment that the common fibular nerve may experience on its way to the foot. As such, BL 39 represents a proximal point to include in such conditions, as one attends also to other sources of compression such as myofascial restriction

Figure 7-83. Both BL 39 ("Outside of the Crook") and BL 40 ("Middle of the Crook") fall along the popliteal crease, or "crook". Note the variety of structures within reach of BL 39, including the plantaris muscle that gives stability to the knee by means of proprioceptive support.

and fascial tension, to be discovered by means of an astute myofascial palpation evaluation.

Although most of the neurologic influence associated with BL 39 involves the common fibular nerve, a branch of the tibial nerve supplies the plantaris muscle, making this a poly-impact site.

Somatovisceral reflexes stimulated by activating afferent endings at BL 39 involve organs supplied by lumbopelvic nerves. This explains the integration of BL 39 into treatments for voiding dysfunction (including urinary and fecal incontinence) and pelvic pain.

Vessels

- **Lateral superior genicular artery and vein:** One of five genicular branches of the popliteal artery and vein that contribute to the formation of the genicular anastomosis, which is a network of vessels around the knee.

Clinical Relevance: Surgical approaches to the knee that take a high lateral approach may damage ligaments, the popliteal tendon, the popliteofibular ligament, the arcuate popliteal ligament, and the lateral collateral ligament, all of which act as principal stabilizers of the caudolateral corner of the knee.[5] Surgery may also damage blood vessels that supply and drain the knee and, as such, impair tissue repair and predispose patients to pain in that region. In addition, the lateral ligament of the knee, an inconstant, small fibrous structure along the lateral end of the femur, may compress the artery but not usually the vein, arguing for treatment of this site with acupuncture, massage, and/or laser therapy.

Indications and Potential Point Combinations

- **Muscle tension in the pelvic limb (posterior thigh or calf):** BL 39, BL 55, BL 56, BL 57, tender myofascial trigger points.
- **Low back pain:** BL 39, along with myofascial trigger points or areas of tension, BL 60, KI 3.
- **Intestinal cramping, distension:** BL 39, ST 36, SP 6.
- **Voiding dysfunction, micturition disorders, fecal incontinence:** BL 39, BL 32, BL 33, BL 34, SP 6, KI 3.
- **Paresis or paralysis of the pelvic limb:** BL 39, identify source and spinal segmental level of dysfunction, including impaired neural transmission lines and select points accordingly.

Evidence-Based Applications

- Acupuncture at SP 6, BL 28, BL 39, and CV 4 provided significant improvement in women diagnosed as having **overactive bladder with urge incontinence**.[1]

BL 40

Wei Zhong "Middle of the Crook"

On the popliteal fossa, at the midpoint of the popliteal crease, midway between the tendons of the biceps femoris and semitendinosus muscles.

Popliteal Fossa

- Where the medial and lateral hamstring group and the medial and lateral heads of the gastronemius muscle divide, they create the diamond-shaped depression at the back of the knee called the popliteal fossa.

Clinical Relevance: Baker cyst is a chronic disorder that can cause compression of the tibial nerve and popliteal vein. Acupuncture and related techniques may help mobilize structures in and around the popliteal fossa, freeing the fascia that further constricts the tibial nerve and popliteal vein.

Popliteal Lymph Nodes

- Six or seven small lymph nodes live embedded in the popliteal fat. One commonly lies beneath the fascial layer near the termination of the small saphenous vein. This lymph node drains the area where the vein receives its tributaries. Another lymph node occupies the site between the popliteal artery and the caudal knee joint. It receives lymphatic tributaries from the joint as well as lymphatic vessels that accompany the genicular arteries. The remaining nodes sit beside the popliteal vessels and receive efferent lymphatic vessels therefrom.

Clinical Relevance: In instances of local edema, treating BL 40 may improve venous and lymphatic drainage of the joint, lessening the pain that frequently develops as a result of tissue tension and restricted biomechanics. However, if one finds an enlarged lymph node anywhere, it is best to identify the source of the swelling and rule out neoplasia or other causes before treating with laser, acupuncture, or manual therapy.

Muscles

- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended. Raises the heel during ambulation. Flexes the leg at the knee joint.
- **Plantaris muscle:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.

Clinical Relevance: While local hamstring trigger points refer pain to the caudal thigh that extends from the transverse gluteal crease to the popliteal region, pain at BL 37 may be referred from the gluteus minimus as well. Trigger points in the posterior portion of the gluteus minimus send pain toward the coccyx

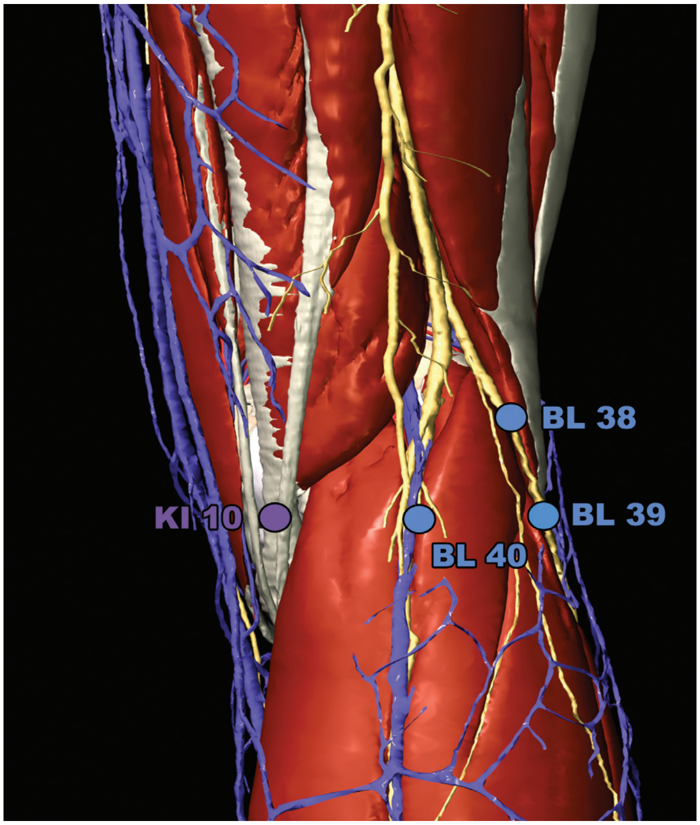

Figure 7-84A. BL 40, along with BL 23, BL 54, BL 60, GB 34, and relevant huatuojiaji points (i.e., sites 0.5 cun from the midline of the spine) are some of the most commonly preferred acupuncture points to treat chronic low back pain, along with additional local and distal points.[17]

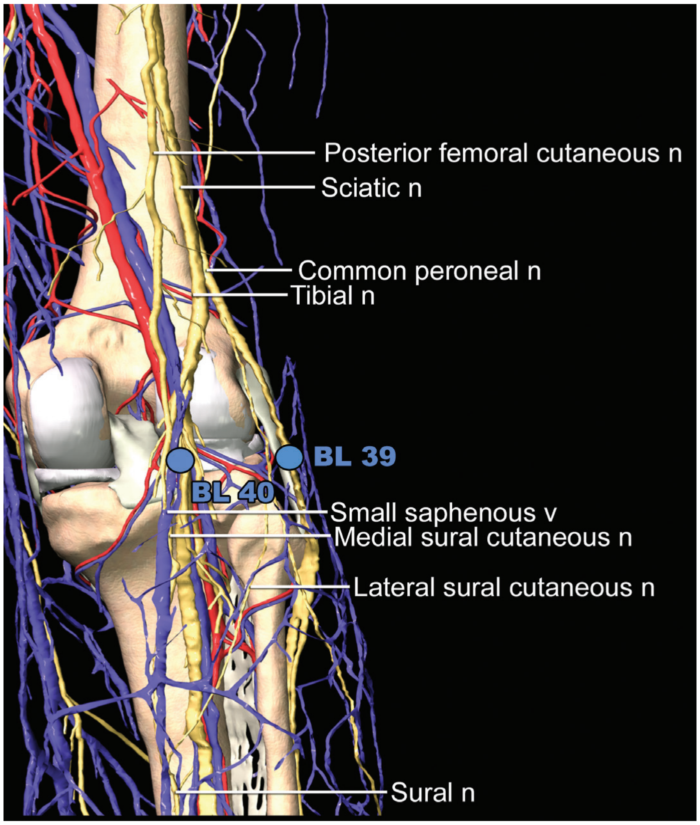

Figure 7-84B. BL 40, "Middle of the Crook", sits at the center of the popliteal fossa, a busy neurovascular highway. This view depicts the neurovascular differences between BL 39 and BL 40; i.e.,, BL 39 relates to the common fibular (formerly called "peroneal") nerve while BL 40 pertains to the tibial nerve.

(BL 35) and the back of the thigh and leg (from BL 36 to BL 56). Trigger point pathology in the biceps femoris at BL 37 can refer pain to the popliteal region, encompassing BL 38, BL 39, and BL 40. Palpatory findings of intense pain at the distal biceps femoris should heighten suspicion of a myofascial trigger point.[10]

The trigger point in the proximal, lateral head of the gastrocnemius muscle refers causes the sensation of pain in the lateral, distal popliteal fossa and proximal calf.

Treatment of BL 40 may also impact the attachment trigger point of the plantaris muscle near to where it attached onto the lateral supracondylar line of the femur. The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to “tennis leg”, a calf injury identified by a “snapping” in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[11] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

Nerves

- **Posterior femoral cutaneous nerve (S1-S3):** Sends cutaneous branches to the buttock and the posterior and uppermost medial thigh surfaces.
- **Medial sural cutaneous nerve:** Innervates the skin on the posterior and lateral leg and lateral side of the foot; forms the sural nerve if it joins the lateral sural cutaneous nerve. Accompanies the small saphenous vein.
- **Tibial nerve (L4, L5, S1-S3):** Supplies all the muscles in the posterior compartment of the leg.

Clinical Relevance: Not all tibial nerve branches carry fibers from all spinal cord segments that supply the tibial nerve. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). This explains why points such as SP 6 and KI 3 appear more routinely in needling formulae for voiding dysfunction than, for example, BL 40 or BL 55.

Symptomatic Baker cysts produce signs and symptoms that implicate compression of the popliteal vein and tibial nerve.[12] Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[13] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[14]

Vessels

- **Popliteal artery:** Supplies the articular capsule and ligaments of the knee joint with its five genicular branches. These branches participate in the formation of the genicular anastomosis around the knee. Muscular branches of the popliteal artery supply the hamstring muscles, the gastrocnemius and soleus muscles, and the plantaris muscle.
- **Popliteal vein:** Lies in the same fibrous sheath as the popliteal artery and runs between the posterior artery and the tibial nerve.
- **Small saphenous vein:** Begins as a continuation of the lateral marginal vein, and ascends along the posterior aspect of the lateral malleolus. It courses along the lateral border of the calcaneal tendon and penetrates deep fascia over the midline of the fibula. The small saphenous vein then ascends between the two heads of the gastrocnemius muscle and pierces the deep popliteal fascia and to empty into the popliteal vein.

Clinical Relevance: Compression of the contents of the popliteal fossa by conditions such as a Baker cyst less commonly compromises function of the popliteal artery due to its higher pressure, stiffer walls, and location deep in the fossa.

Popliteal venous aneurysms can occur that lead to thrombosis and pulmonary emboli, even in the anticoagulated patients.[15] Popliteal artery aneurysms and ganglia can also compress the tibial nerve.

Compartment syndromes may develop after phlebitis episodes that affect veins in the popliteal fossa, producing collateral vein thrombosis.

A spontaneous compartment syndrome may result from a varicosed popliteal vein.

Treatment for neurovascular compression by means of acupuncture and related techniques should be performed carefully but may improve circulation and nerve health by reducing myofascial tension.

Indications and Potential Point Combinations

- **Back, sacral, hip, or pelvic limb pain, sciatic-related pain or weakness:** Identify dysfunctional joint, soft tissue, nerve, or spinal segmental contributions and treat accordingly. BL 40, BL 23, BL 25, BL 60, as indicated by the dysfunction.
- **Micturition disorders, fecal or urinary incontinence**: BL 40, BL 23, BL 28, BL 32, BL 39, BL 40, SP 6.
- **Nocturnal enuresis:** BL 40, HT 7, CV 3, BL 28.[16]

Evidence-Based Applications

- Bloodletting of “the engorged vein” near BL 40, either alone or with SI 3 needling improved the symptoms related to **acute lumbar strain.**[1,2] **(Note: Needling “engorged veins” in the**

- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L 4 and L 5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[3]

- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) **improved the orthopedic management of chronic low back pain.**[4]

- EA at BL 23, BL 25, BL 40, and SP 6, combined with back exercises provided more relief of **chronic low back pain** and improvement in functional capacity compared to exercise alone; the benefits were maintained at a 3-month follow-up.[5]

- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[6]

- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with **lumbar disc protrusion** resulted in significant pain reduction.[7]

- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain**, even at a 3 month follow-up.[8]

- Electroacupuncture at BL 40 and BL 57 relieved **local ankle spasticity** in a child with mild spastic hemiplegic cerebral palsy.[9]

BL 41

Fu Fen "Attached Branch"

On the cranial thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T2, level with BL12. An alternate and neuroanatomically more precise location places BL 41 at the lateral border of the iliocostalis muscle in the 2nd intercostal space. See Figure 7-86A for comparison of both point placements.

CAUTION: This is one of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) where deep needling can cause pneumothorax. This risk is higher with the outer BL line points than the parallel inner line.[1]

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Serratus posterior superior muscle:** Elevates the upper four ribs, thereby raising the sternum and increasing the anteroposterior diameter of the thorax.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: A myofascial trigger point in the serratus posterior superior muscle, just medial to the angle of the scapula, causes pain in the cranial scapula, caudal deltoid, olecranon tip, and wrist, overlapping with the TH, PC, and HT channels. Rhomboid trigger points refer to the medial border of the scapula. Erector spinae trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **C5, C8, T2 and T3 spinal nerves:** Dorsal rami innervate skin, bones, joints, muscles of the back. Ventral rami form intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **T2-T5 spinal nerves, ventral rami (2nd to 5th intercostal nerves):** Innervate serratus posterior superior muscle.
- **Dorsal scapular nerve (C4, C5):** innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: BL 41 begins a series of points making up the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also

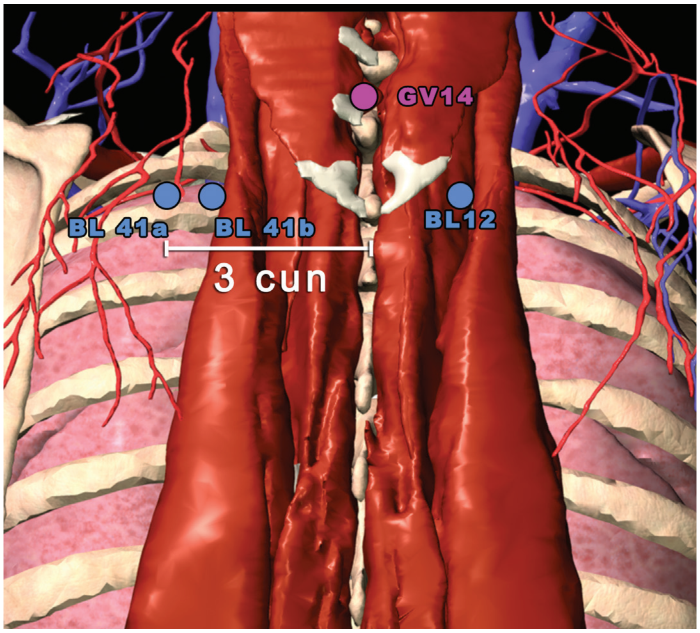

Figure 7-86A. Two ways exist to locate BL points of the outer channel. In this image, BL 41a identifies the location determined by cun count. BL 41b puts the point at the lateral iliocostalis border. As shown by the erector spinae muscle group reproduced in this figure, the latter point location method will place outer BL line points at variable distances from the midline. Finding points in this manner affords a more accurate neuroanatomic location than strict implementation of cun measurements.

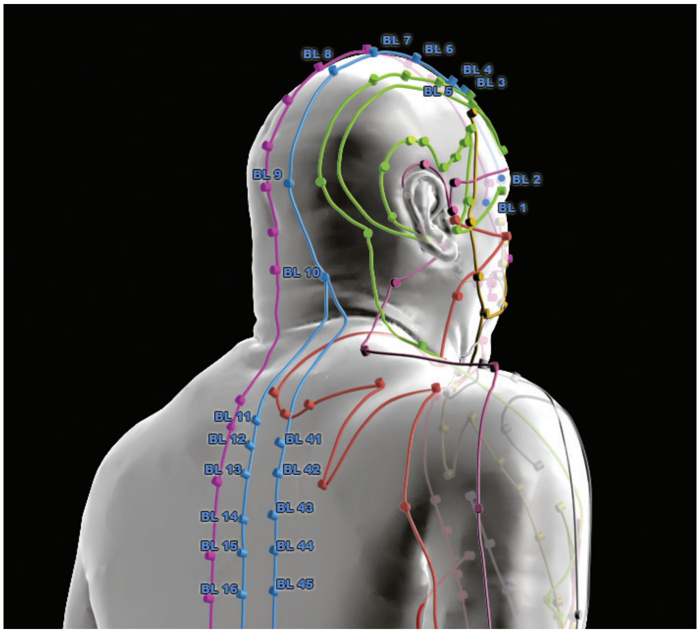

Figure 7-86B. This "glassman" image illustrates why BL 41 earns the name "attached branch", representing the first point on the outer BL line.

represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[2]

The outer Bladder line points echo the effects of inner BL points on visceral function through reflexes in the spinal cord.[3] Although BL 41 is not paired with an organ traditionally, but its indications resonate with those of BL 12 in terms of treating the upper airways and immune system.

Figure 7-87 outlines the structures within reach of a needle entering BL 41 and BL 12. Neurologically, BL 41 relates more closely to the ventral ramus of the spinal nerve than does its dermatomal partner, BL 12.

Vessels

- **2nd posterior intercostal artery:** Arises from the supreme intercostal artery, a branch of the costocervical artery of the subclavian artery. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **2nd posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. The 1st through the 3rd intercostal veins either empty into the brachiocephalic vein or superior vena cava. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: The intercostal artery becomes exposed within the intercostal space in the territory described by the BL channels.[4] Contrary to most artists' renditions of the posterior intercostal vessels, the posterior intercostal neurovascular bundles exhibit variable tortuosity.[5] Inadvertent puncture of these vessels can cause hematoma or hemothorax, which are serious consequences of percutaneous needling. Usually, acupuncture needling will not reach the depth of the intercostal vessels because coursing through the chest wall could induce pneumothorax.

Indications and Potential Point Combinations

- **Tension or pain in the upper back, neck, shoulder:** Check first for trigger points; consider BL 41 for tenderness to palpation in this shoulder region. Muscles accessible at this level include the trapezius, rhomboideus major, and the posterior lip of the serratus anterior muscle as it attaches to the medial border of the scapula.
- **Numbness in the thoracic limb:** BL 41 to reduce regional neural compression and to provide input to spinal segments governing thoracic limb function. Add distal points to facilitate nerve communication along compromised pathways. Add spinal segmental points to address the affected area cranial and caudal to the dysfunction.
- **Early viral illness:** BL 41, BL 12, BL 13, ST 36, LI 4.

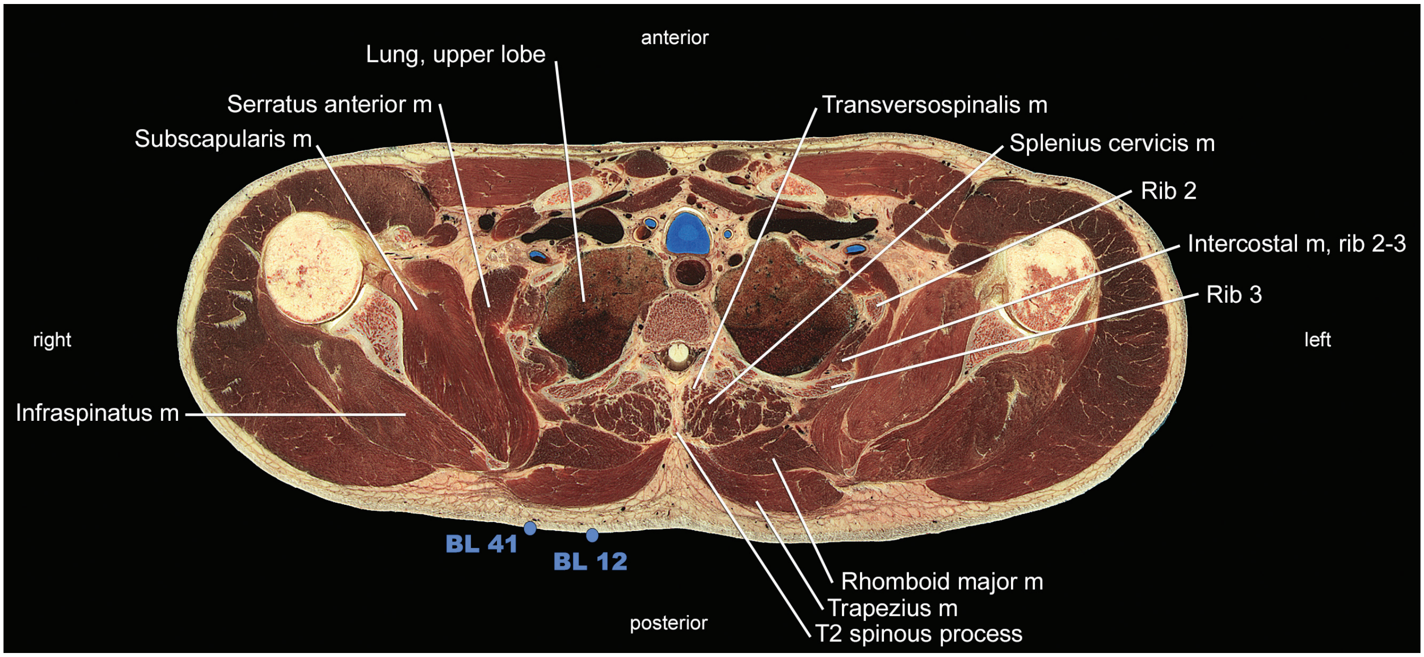

Figure 7-87. While a large distance exists between the skin surface at BL 41 and the upper lobe of the lung in this specimen, far less tissue would protect the lungs in a thin, geriatric patient.

BL 42

Po Hu "Door of the Corporeal Soul"

On the cranial thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T3, level with BL 13. An alternate and neuroanatomically more precise location places BL 42 at the lateral border of the iliocostalis muscle in the 3rd intercostal space.

CAUTION: This is one of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) where deep needling can cause pneumothorax. This risk is higher with the outer BL line points than the parallel inner line.[1]

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.

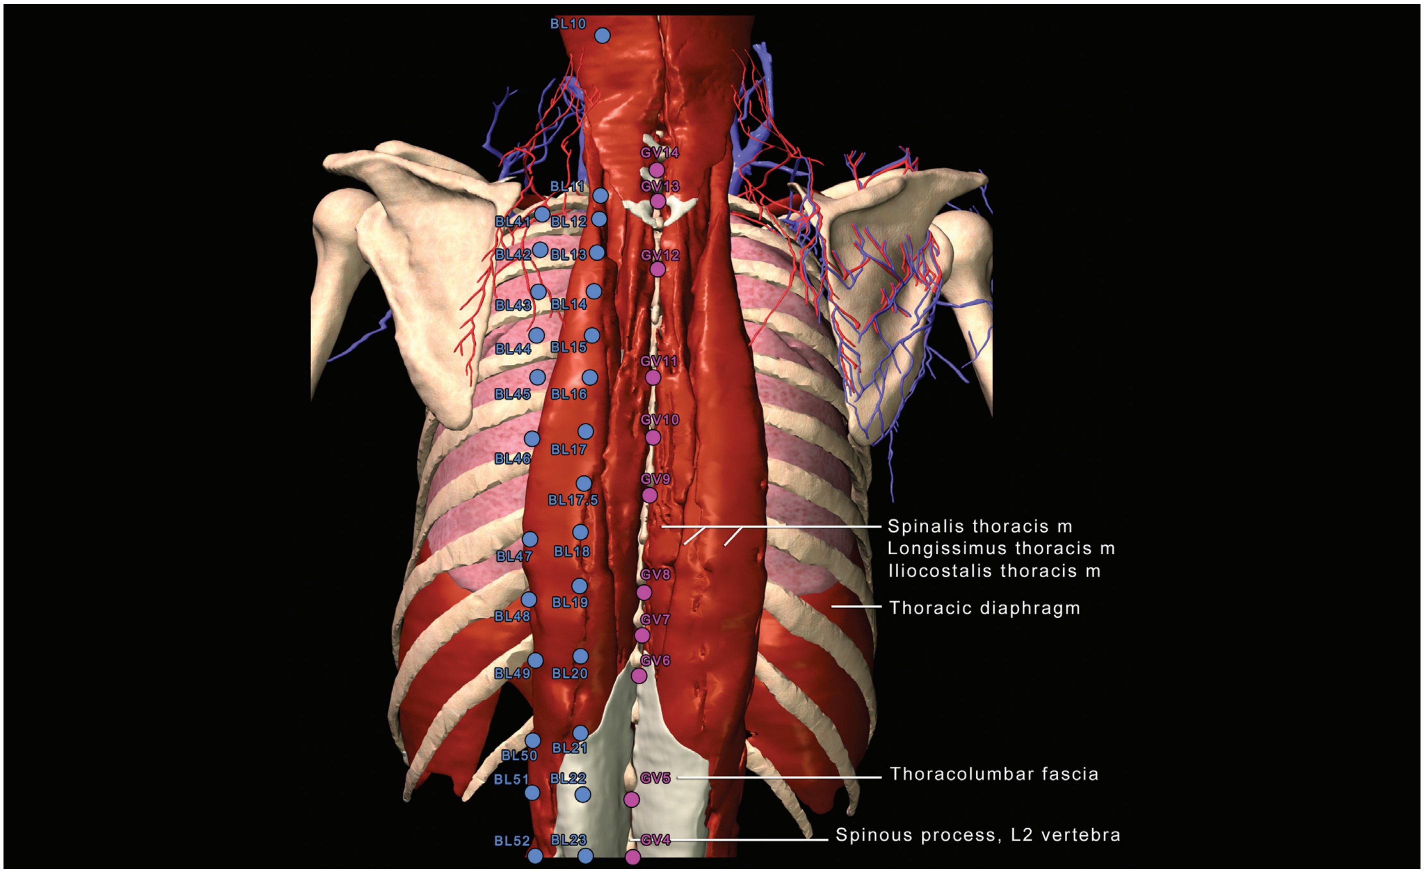

Figure 7-88. In Chinese medicine, the term "Corporeal Soul" in the descriptive name for BL 42, "Door of the Corporeal Soul" refers to that part of one's being which initiates and drives physiologic processes. Because the lungs inhale air (Qi), the oxygen taken in does indeed support bodily life; without it, one will perish. The lungs in this image extend well caudal to BL 13 and BL 42 but their sympathetic fibers arise from the cranial thoracic spinal segments shared by these two points. Points in this image along both the inner and outer BL channel segments have been placed according to cun (body inch) count rather than topographical features such as the medial and lateral border of the iliocostalis muscle. If one contours the BL channels to these muscle borders, both trajectories become curvilinear rather than straight lines. Finding points based on actual anatomy rather than strict measurements translates into more reliable neuroanatomic localization and consistent neuromodulatory outcomes.

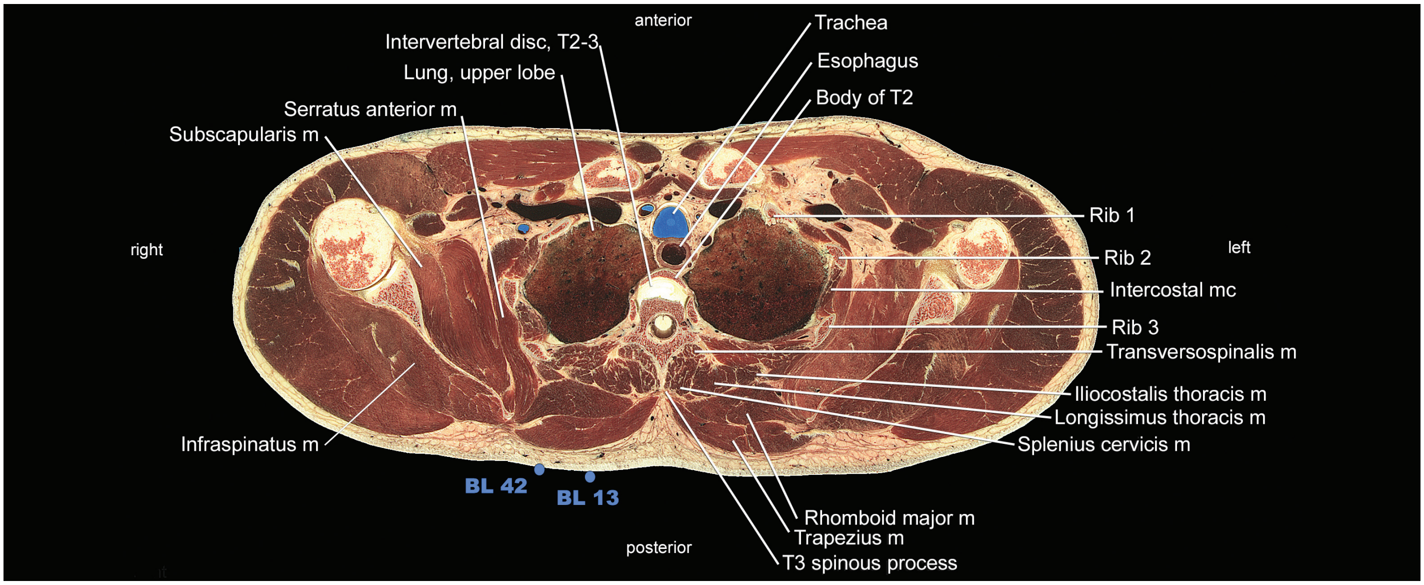

Figure 7-89. Several layers of robust muscles deep to BL 42 protect the lung in this cross section. However, thin, cachectic, geriatric or other patients with atrophic or underdeveloped musculature would exhibit more risk for pneumothorax with deep needling at this "Door of the Corporeal Soul".

nerves): Innervate serratus posterior superior muscle.

- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: BL 42 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[3]

The outer Bladder line echoes the effects of its parallel partner by indirectly influencing visceral function through reflexes that occur in the spinal cord.[4]

Figure 7-89 compares the anatomy beneath BL 42 and BL 13. Neurologically, BL 42 relates more closely to the ventral ramus of the spinal nerve than does its dermatomal partner, BL 13, the lung "Back Shu" point.

Vessels

- **3rd posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin.

Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.

- **3rd posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. The 1st through the 3rd intercostal veins either empty into the brachiocephalic vein or superior vena cava. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: The intercostal artery becomes exposed within the intercostal space in the territory described by the BL channels.[5] Contrary to most artists' renditions of the posterior intercostal vessels, the posterior intercostal neurovascular bundles exhibit variable tortuosity. Inadvertent puncture of these vessels can cause hematoma or hemothorax, which are serious consequences of percutaneous needling. Usually, acupuncture needling will not reach the depth of the intercostal vessels because coursing through the chest wall could induce pneumothorax.

Indications and Potential Point Combinations

- **Respiratory problems:** BL 42, BL 13, BL 23, ST 36, LU 7.
- **Stiffness in the neck or upper back:** BL 42, other tender myofascial trigger points in the upper thorax and neck.

Evidence-Based Applications

- Symptoms of **chronic emotional disorders** improved following injection of ultra-low-dose triamcinolone into tender points along the outer Bladder line, from BL 42-BL 46.[2]

BL 43

Gao Huang Shu "Vital Region Shu"

On the cranial thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T4, level with BL 14. An alternate and neuroanatomically more precise location places BL 43 at the lateral border of the iliocostalis muscle in the 4th intercostal space. See Figures 7-90A and 7-90B in order to compare the locations derived by strict adherence to the usual definition versus finding the point on the basis of neuroanatomically relevant landmarks.

One of several acupuncture points (including LU 2; ST 11-ST 18; KI22-KI27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Trapezius muscle:** The middle fibers of the trapezius muscle retract the scapula (i.e., pull it in a caudal direction).
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Serratus posterior superior muscle:** Elevates the upper four ribs, thereby raising the sternum and increasing the anteroposterior diameter of the thorax.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: A myofascial trigger point in the serratus posterior superior muscle, just medial to the angle of the scapula, causes pain in the cranial scapula, caudal deltoid, olecranon tip, and wrist, overlapping with the TH, PC, and HT channels. Rhomboid trigger points refer to the medial border of the scapula. Erector spinae trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **C8-T4 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.
- **T2-T5 spinal nerves, ventral rami (2nd to 5th intercostal nerves):** Innervate serratus posterior superior muscle.

Clinical Relevance: BL 43 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back

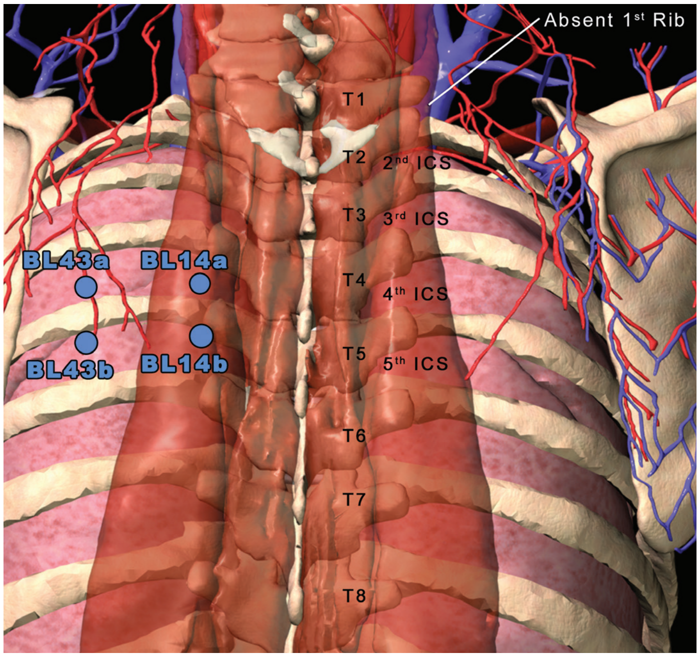

Figure 7-90A. In this image, BL 14 (a and b) falls 1.5 cun from the midline, and BL 43 (a and b), 3 cun. The appropriate level where BL 14a and BL 43a should land is in the 4th intercostal space associated with the 4th intercostal vein, artery, and nerve. On the other hand, following the classical definition puts BL 14b and BL 43b in the 5th intercostal space, level with the caudal border of the T4 spinous process.

Figure 7-91. BL 43, or "Vital Region Shu", is the outer BL line counterpart in relation to BL 14 (Pericardium Back Shu). Its Chinese name of "gao huang' means "fat membrane", likely referring to pericardial fat or to the pericardium itself. This cross section reveals how deep needling at BL 43 could reach the lung whereas acupuncture at BL 14 might first encounter bone.

pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[3]

The outer Bladder line echoes the effects of its parallel partner by indirectly influencing visceral function through reflexes that occur in the spinal cord.[4]

Vessels

- **4th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **4th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: The intercostal artery becomes exposed within the intercostal space in the territory described by the BL channels.[5] Contrary to most artists' renditions of the posterior intercostal vessels, the posterior intercostal neurovascular bundles exhibit variable tortuosity. Inadvertent puncture of these vessels can cause hematoma or hemothorax, which are serious consequences of percutaneous needling. Usually, acupuncture needling will not reach the depth of the intercostal vessels because coursing through the chest wall could induce pneumothorax.

Indications and Potential Point Combinations

- **Cough, asthma:** BL 43, BL 13, BL 42, BL 23, LU 5, LI 4.
- **Back pain or stiffness:** BL 43 and local trigger points.

Evidence-Based Applications

- Symptoms of **chronic emotional disorders** improved following injection of ultra-low-dose triamcinolone into tender points along the outer Bladder line, from BL 42-BL 46.[2]

BL 44

Shen Tang "Hall of the Spirit"

On the upper thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T5, level with BL 15. An alternate and neuroanatomically more precise location places BL 44 at the lateral border of the iliocostalis muscle in the 5th intercostal space.

One of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Trapezius muscle:** The musculotendinous part provides added resistance to needle insertion. Inferior fibers depress the scapula and lower the shoulder.
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the erector spinae bend the vertebral column in a lateral direction; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Rhomboid trigger points refer to the medial border of the scapula. Erector spinae trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 44 that extends around the trunk to the chest could cause diagnostic confusion and cause some to interpret myofascial referred pain as cardiac in origin.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T2-T5 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: BL 44 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal

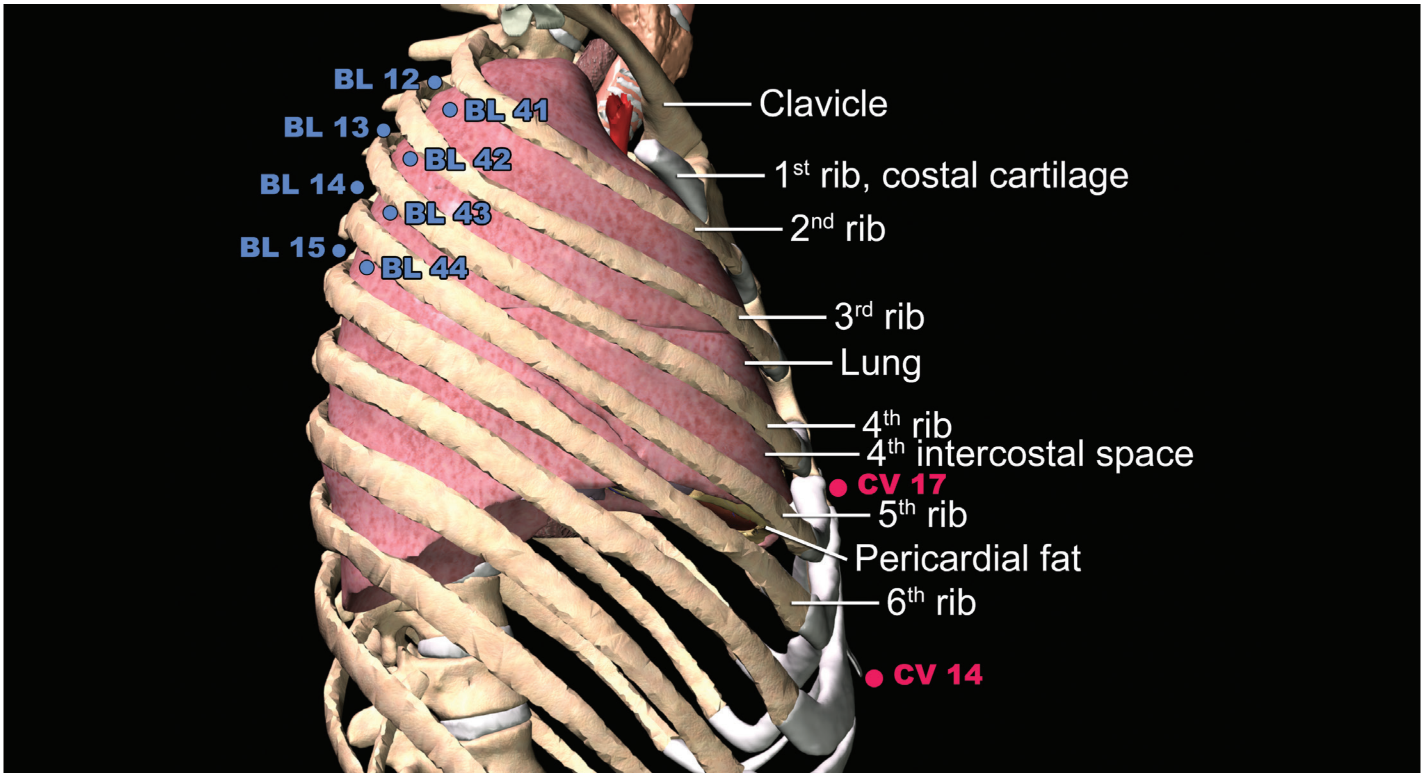

Figure 7-92. BL 44 resides in the 5th intercostal space with its inner BL line partner, BL 15, the Back Shu points of the heart. In Chinese medicine, the heart houses the spirit, which explains why they called BL 44 "Hall of the Spirit". This section of the trunk corresponds closely with the heart and pericardium from a neuroanatomic perspective. The T1-T5 spinal cord segments mediate sympathetic somatovisceral and viscerosomatic reflexes between the cardiac system and the upper back. The 5th intercostal nerves courses along the 5th intercostal space from back to front, arriving at the midline near the Front Mu point for the heart, CV 14. The Chinese medicine association of the heart with the mind lends insight into why BL 44 might appear in a treatment formula for stroke patients suffering from Broca's aphasia.[7] Some associate the clinical benefits derived from stimulating points along the outer BL line with the "emotional" aspects ascribed to the paired inner BL line point. For BL 44, then, the effects of needling would pertain to the more spiritual aspects of cardiac function.

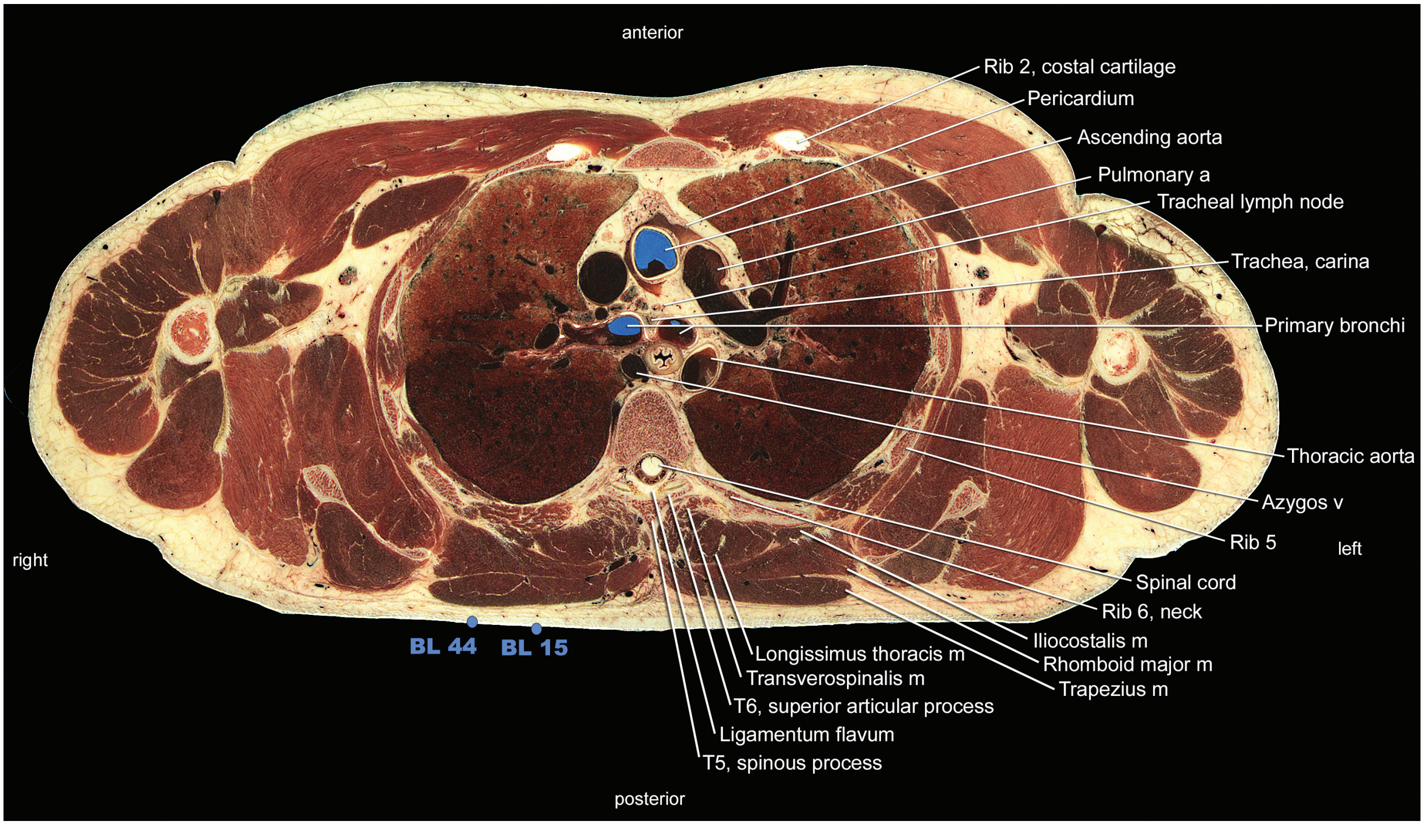

Figure 7-93. The thick, heavy musculature beneath BL 44 and BL 15 makes these sites prime targets for trigger point deactivation.

nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[3]

The outer Bladder line echoes the effects of its parallel partner by indirectly influencing visceral function through reflexes that occur in the spinal cord.[4] In the case of BL 44 and BL 15, the internal organ with which they correspond is the heart.

Vessels

- **5th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **5th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: The intercostal artery becomes exposed within the intercostal space in the territory described by the BL channels.[5] Contrary to most artists' renditions of the posterior intercostal vessels, the posterior intercostal neurovascular bundles exhibit variable tortuosity.[6] Inadvertent puncture of these vessels can cause hematoma or hemothorax, which are serious consequences of percutaneous needling. Usually, acupuncture needling will not reach the depth of the intercostal vessels because coursing through the chest wall could induce pneumothorax.

Indications and Potential Point Combinations

- **Emotional upset: agitation, insomnia:** BL 44, BL 15, PC 6, PC 7, HT 3, HT 7, LR 3.
- **Upper back pain:** BL 44, other trigger points in the region.

Evidence-Based Applications

- Symptoms of **chronic emotional disorders** improved following injection of ultra-low-dose triamcinolone into tender points along the outer Bladder line, from BL 42-BL 46.[2]

BL 45

Yi Xi "Sigh", "Hiccup", or "Sob"

On the upper thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T6, level with BL 16. The line describing 3 cun from the midline is continuous with the medial border of the scapula in the thoracic region, when the shoulder is relaxed. An alternate and neuroanatomically more precise location places BL 45 at the lateral border of the iliocostalis muscle in the 6th intercostal space. One of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Trapezius muscle:** The inferior fibers depress the scapula and lower the shoulder.
- **Rhomboideus major muscle:** Retracts and rotates the scapula; assists the serratus anterior muscle in holding the scapula against the thoracic wall; holds the scapula in place the scapula while the thoracic limb is moving.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.

Clinical Relevance: Rhomboid trigger points refer to the medial border of the scapula. Erector spinae trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 45 that extends around the trunk to the chest could cause diagnostic confusion and cause some to interpret myofascial referred pain as cardiac in origin.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T3-T6 spinal nerves:** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **Dorsal scapular nerve (C4, C5):** Innervates the rhomboid muscles, entering at their deep surface. Arises chiefly from C5 and often receives contribution from C4. May provide fibers to the levator scapulae.

Clinical Relevance: BL 45 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[4]

The outer Bladder line echoes the effects of its parallel partner by indirectly influencing visceral function through reflexes that occur in the spinal cord.[5] In the case of BL 45, however, its inner line companion is the Back Shu point for the Governing Vessel (BL 16). BL 16 associates not with a viscus but with a vascular network that includes the azygous (also spelled "azygos") vein, shown in Figure 7-94b, ventral to the vertebral body. The azygous vein enters the superior vena cava at or below the level of BL 16/BL 45 in most cases. This horizontal plane includes the bifurcation of the pulmonary trunk.[6] The azygous vein may join the caval venous system directly or it may empty indirectly by way of the hemiazygous and accessory hemiazygous veins.

Vessels

- **6th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin.

Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.

- **6th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Neuromodulation at BL 45 may improve circulation to and from the structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and

massage benefit blood flow and venous return, which supports soft tissue health and restoration.

Indications and Potential Point Combinations

- **Cough, asthma, dyspnea:** Check for intercostal trigger points; take BL45 if tender. Add BL 12, BL 13, BL 23, LI 4, ST 36.
- **Shoulder or back pain, stiffness:** BL 45, other local points that exhibit tenderness to palpation. Address spinal segments pertaining to somatic dysfunction.

Evidence-Based Applications

- Acupuncture provided an effective alternative to medication for the treatment of renal colic with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[2]
- Symptoms of chronic emotional disorders improved following injection of ultra-low-dose triamcinolone into tender points along the outer Bladder line, from BL 42-BL 46.[3]

BL 46

Ge Guan "Diaphragm Gate"

On the upper thorax, in a groove medial to the vertebral border of the scapula, 3 cun lateral to the caudal border of the spinous process of T7, level with BL 17. The line describing 3 cun from the midline is continuous with the medial border of the scapula in the thoracic region, when the shoulder is relaxed. Approximately level with the inferior angle of the scapula. BL 46 sits alongside BL 17 in the 7th intercostal space.

One of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1] Because this point lies near the triangle of auscultation, the risk of entering the lung increases.

Muscles

- **Trapezius muscle**: The inferior fibers depress the scapula and lower the shoulder.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the iliocostalis sidebends the vertebral column; acting bilaterally, it extends the spine.

Clinical Relevance: Erector spinae trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 46 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as cardiac in origin. Trigger points in the trapezius at this level typically refer pain that ascends toward BL 11 and/or GB 21.

Nerves

- **Spinal accessory nerve (CN XI):** Innervates the trapezius, along with fibers from C3 and C4, of the cervical plexus.
- **T3-T7 spinal nerves:** Dorsal ramus innervates skin, bones, joints, and erector spinae at this level. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: BL 46 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[4]

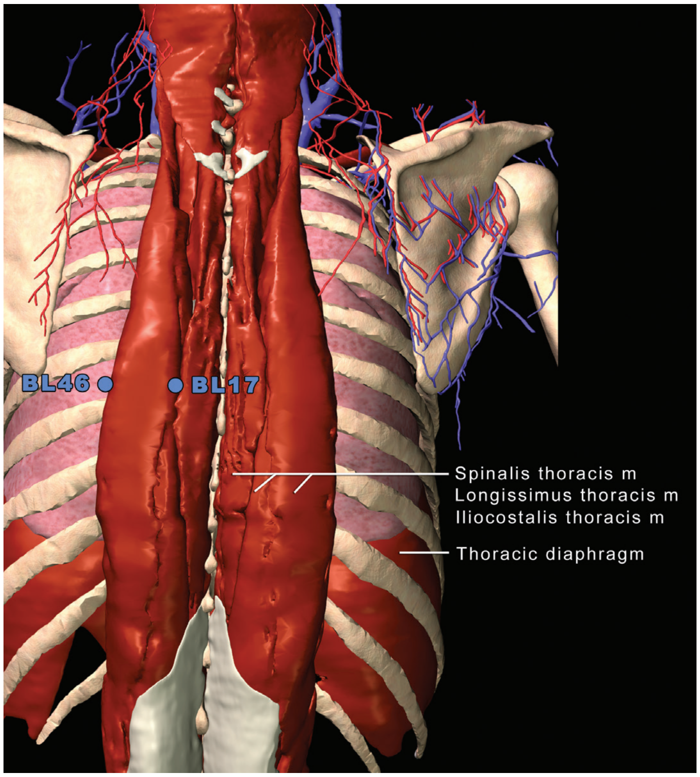

Figure 7-95. BL 46, like BL 17, should fall within the 7th intercostal space, level with the inferior angle of the scapula, on the lateral border of the iliocostalis thoracis muscle. BL 46, "Diaphragm Gate", harkens the presence of the diaphragm, which actually attaches to the back below this level. This dome-shaped musculofibrous septum divides the thoracic cavity from its abdominal counterpart. Its attachments span from the dorsum of the xiphoid process to the inner surfaces of the cartilaginous portions of the lower six ribs, onto the lumbocostal arches and vertebrae by means of its crura, or pillars.

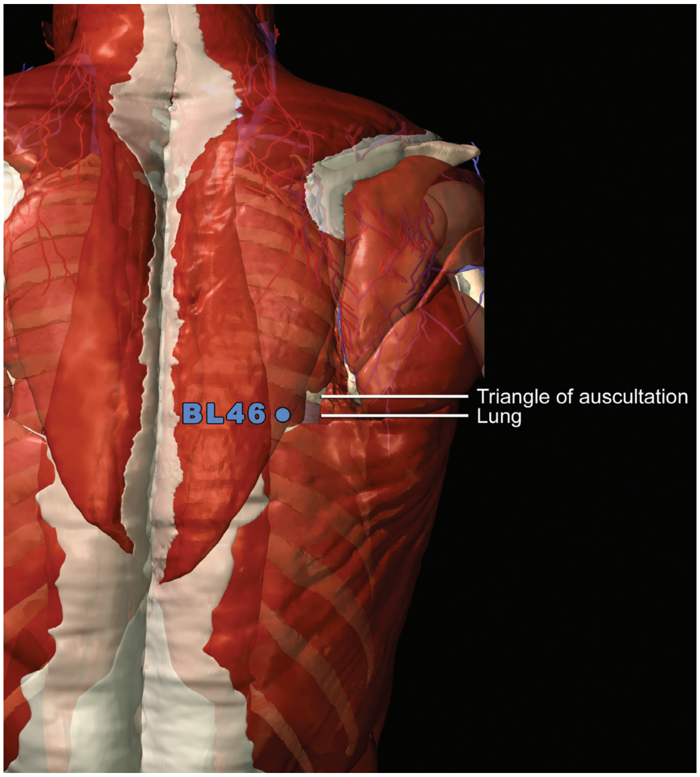

Figure 7-96. BL 46 lands close to or falls within the "triangle of auscultation". This site gains significance due to the relative ease of auscultating lung sounds on account of less soft tissue interference. At the same time, however, less muscle means higher risk of pneumothorax with needling this location.

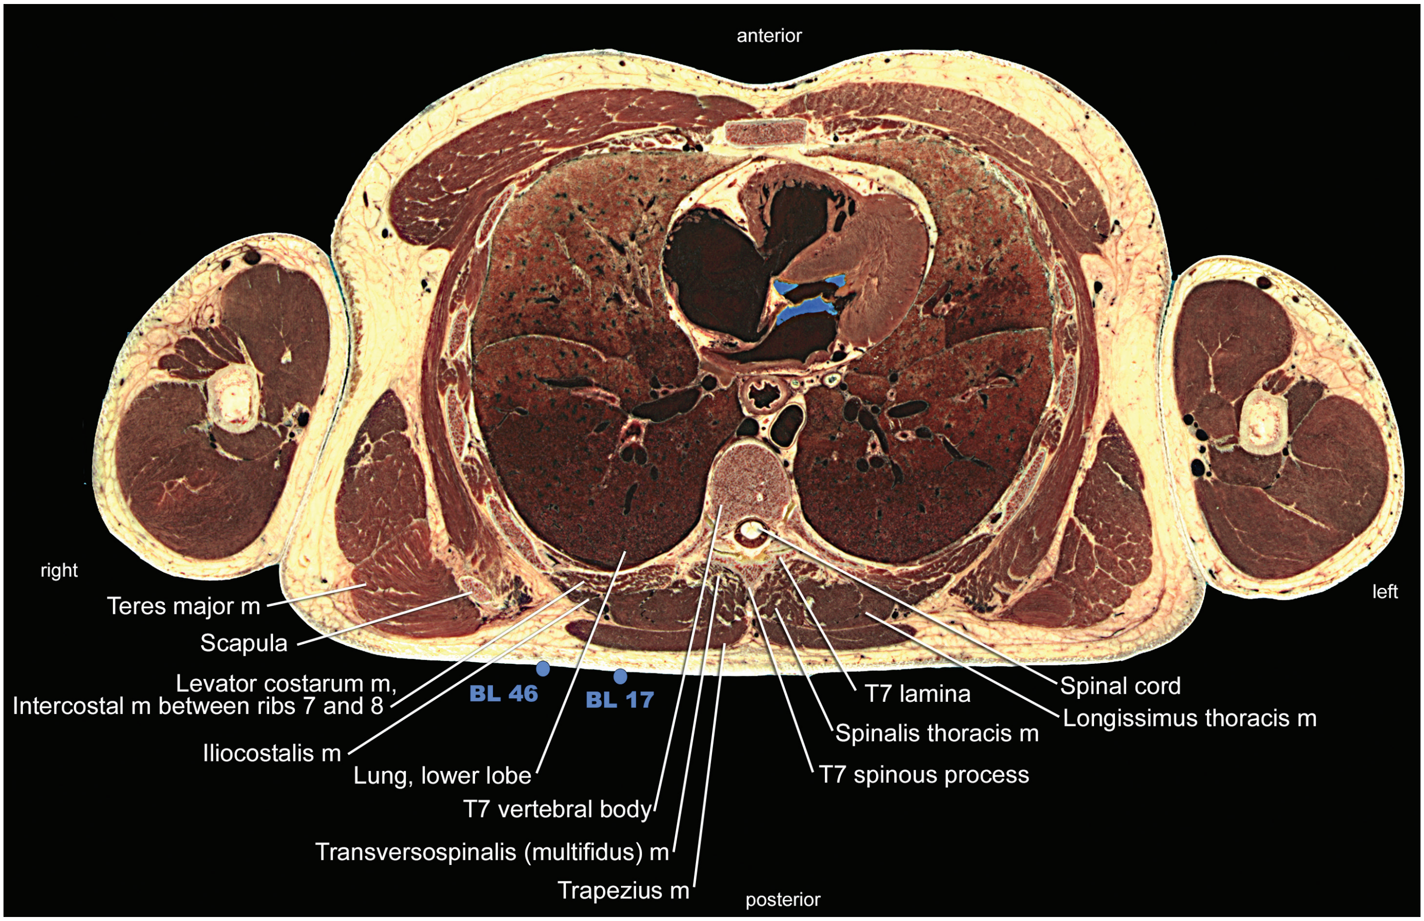

Figure 7-97. The window to the lungs, the triangle of auscultation, appears here deep to BL 46.

The outer Bladder line points echo the effects of the inner group by stimulating similar spinal nerves and cord segments.[5] In the case of BL 46, its inner line companion is the Back Shu point for the diaphragm (BL 17). Figure 7-95 compares the relative locations of the dorsal aspects of the diaphragm in relation to BL 17 and BL 46.

Vessels

- **7th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **7th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Neuromodulation at BL 46 may improve circulation to and from the structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and repair. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation.

Indications and Potential Point Combinations

- **Local pain:** Only needle if necessary due to local pain or restriction; caution required near the triangle of auscultation.

Evidence-Based Applications

- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[2]
- Symptoms of **chronic emotional disorders** improved following injection of ultra-low-dose triamcinolone into tender points along the outer Bladder line, from BL 42-BL 46.[3]

BL 47

Hun Men “Gate of the Ethereal Soul”

Below the inferior angle of the scapula, 3 cun lateral to the caudal border of the spinous process of T9, level with BL 18. BL 47 lives in the 9th intercostal space beside its partner, BL 18.

One of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1]

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the iliocostalis sidebends the vertebral column; acting bilaterally, it extends the spine.

Clinical Relevance: Trigger points in the latissimus dorsi muscle refer strongly to the region inhabited by BL 47 and BL 48. From here, the trigger-point-issued pain climbs to TH 14 and then down the thoracic limb, following the Triple Heater channel to the fingers. Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 47 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as visceral in origin. Serratus posterior inferior trigger points produce pain in the BL 47 to BL 51 region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T5-T9 spinal nerves:** Dorsal ramus innervates skin, bones, joints, and erector spinae at this level. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: BL 47 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[3]

The outer Bladder line points echo the impact of points on

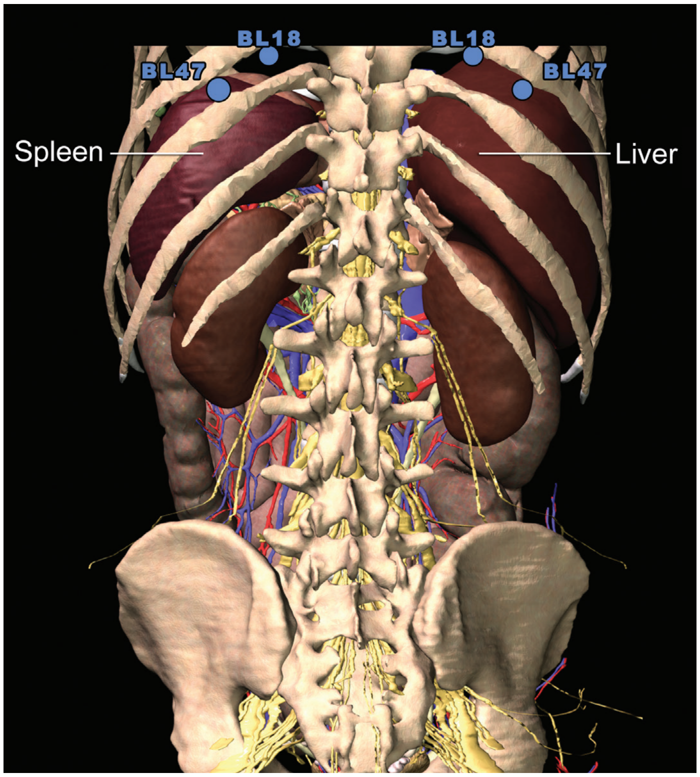

Figure 7-98A. Chinese medical philosophy holds that the liver houses the “ethereal soul” that governs imagination, intuition, and dreaming. This contrasts with BL 42, “Po Door”, where “Po” stands for the “corporeal soul” which we now understand as physiologic processes. BL 47 sits atop the liver as a “Gate to the Ethereal Soul”, similar to the way in which BL 42, “Po Door”, lands atop the lungs.

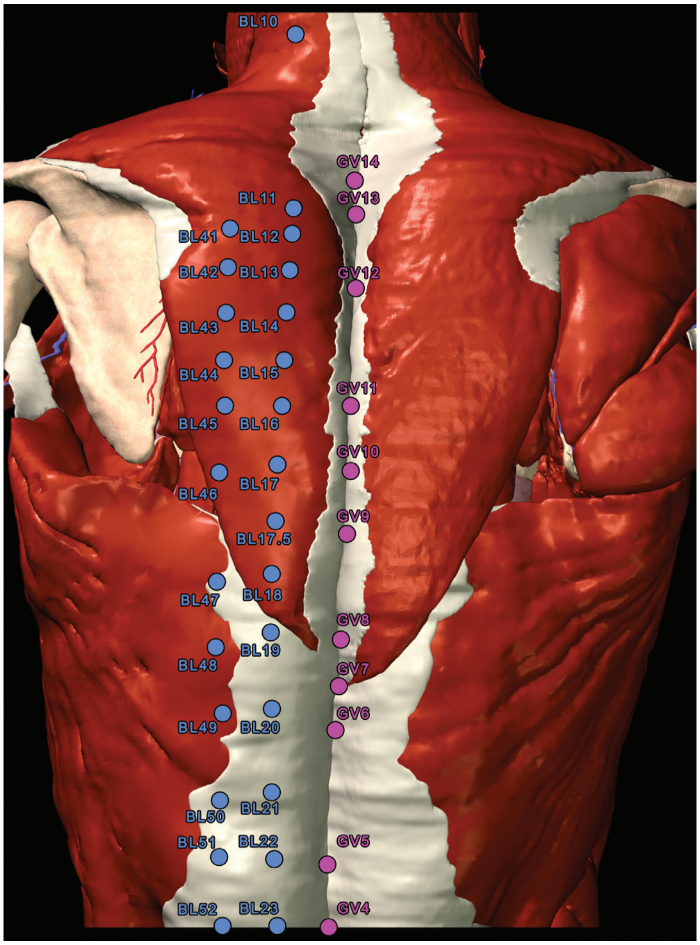

Figure 7-98B. At BL 47, the latissimus dorsi muscle replaces the trapezius as the superficial muscle layer overlying the erector spinae.

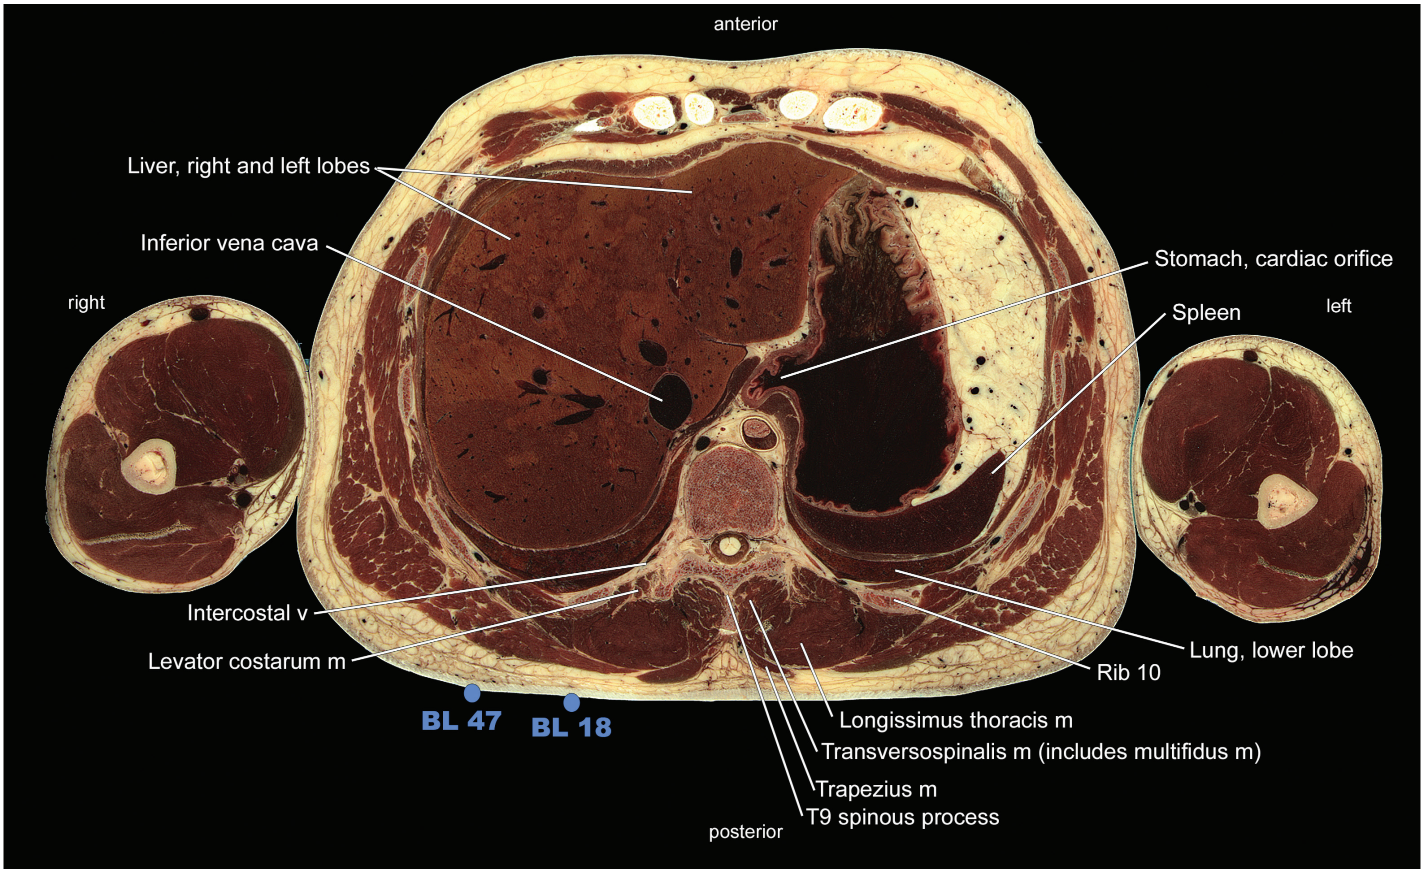

Figure 7-98C. The latissimus dorsi is the thick, most superficial muscle embracing the dorsolateral trunk. This cross section describes how, from a muscular perspective, the an acupuncture needle would first encounter the latissimus dorsi at BL 47, followed by the lateral border of the erector spinae muscle column (specifically, the iliocostalis thoracis).

the inner line by stimulating similar spinal nerves and cord segments.[4] In the case of BL 47, the inner line companion is the Back Shu point for the liver (BL 18). Figure 7-98C exposes how prominent the liver has become on this horizontal plane, illustrating the anatomical linkage between these points and the liver.

Vessels

- **9th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **9th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Neuromodulation at BL 47 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation.

Indications and Potential Point Combinations

- **Pain in the chest or lateral thorax:** BL 47, other tender locations and BL points on related spinal segmental levels. Assess for intercostal restriction and discomfort.
- **Back pain:** BL 47, other tender locations and BL points on related spinal segmental levels. If pain emanates from the spine itself, add GV points and/or Huatuojiaji points (1/2 lateral to the midline).
- **Insomnia:** BL 47, BL 18, HT 3, HT 7, PC 7.
- **Liver disorders:** BL 47, BL 18, LR 14, GB 24.

Evidence-Based Applications

- Acupuncture provided an effective alternative to medication for the treatment of **renal colic** with acupuncture points BL 21, BL 22, BL 23, BL 24, BL 25, BL 45, BL 46, and BL 47.[2]

BL 48

Yang Gang "Yang's Key Link" or "Yang Headrope"

On the lateral border of the erector spinae muscle column in the 10th (second to last) intercostal space, which BL 19 shares.

One of several acupuncture points (including LU 2; ST 11-ST 18; KI 22-KI 27; GB 21; and BL 41-BL 50) through which deep needling can cause pneumothorax.[1] However, the risk of pneumothorax decreases from BL 48 to BL 50 because abdominal organs replace thoracic structures caudal to, or below, the diaphragm. Figure 7-99A illustrates the transition from BL 18/BL 47 to BL 19/BL 48. At the level of the upper pair, the empty thoracic cage identifies the location of the lungs, though one should remember that the relationships in this image show the organ layout in exhalation.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the iliocostalis sidebends the vertebral column; acting bilaterally, it extends the spine.

Clinical Relevance: Trigger points in the latissimus dorsi muscle refer strongly to the region inhabited by BL 47 through BL 49. From here, the trigger-point-issued pain climbs to TH 14 and then down the thoracic limb, following the Triple Heater channel to the fingers. Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 48 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as visceral in origin. Serratus posterior inferior trigger points produce pain in the BL 47 to BL 51 region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T6-T10 spinal nerves:** Dorsal ramus innervates skin, bones, joints, and erector spinae at this level. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: BL 48 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[2]

The outer Bladder line points echo the impact of points on the inner line by stimulating similar spinal nerves and cord segments.[3] In the case of BL 48, the inner line companion is the Back Shu point for the gallbladder (BL 19). Figure 7-99B exposes how prominent the liver remains at this level, though it does appear in the upcoming cross section for BL 20/BL 49. Figure 7-99A describes how the intercostal spaces angle downward laterally, which may mean that the actual cross section for BL 48 may be somewhere between Figure 7-99B and Figure 7-100B.

Vessels

- **10th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **10th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

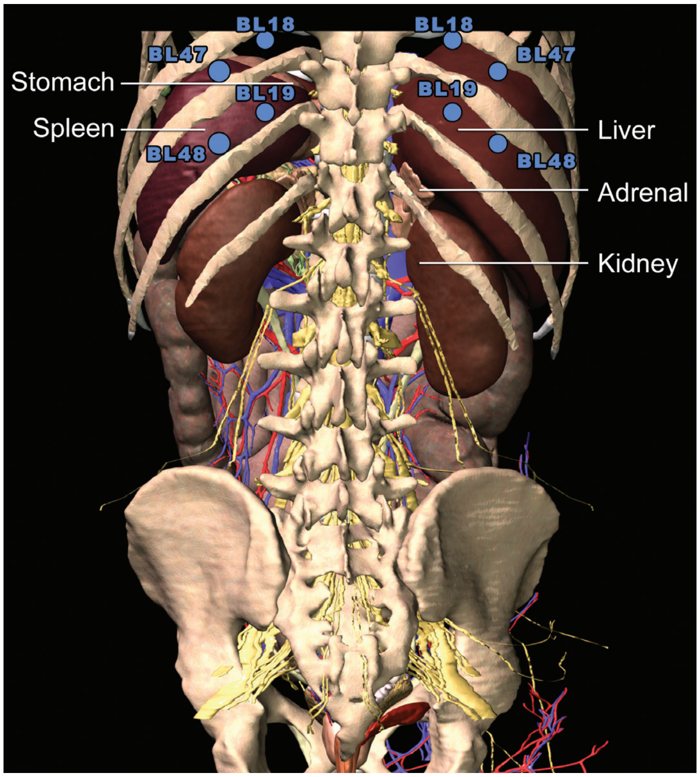

Figure 7-99A. BL 48, "Yang's Key Link", marks the level at which Back Shu points appear in cross section that relate to Yang (hollow) as opposed to Yin (solid) organs. Previously, the associated organs were all considered Yin: lung, pericardium, heart, and liver. Now, BL 48 partners with BL 19, affiliated with the gallbladder. Upcoming Yang Back Shu associations include the stomach (BL 21), the triple heater (BL 22), the large intestine (BL 25), the small intestine (BL 27), and the urinary bladder (BL 28).

Figure 7-99B. This cross section illustrates how the tissue deep to BL 48 has thinned in comparison with more cranial levels and how deep needling may affect the liver.

Clinical Relevance: Neuromodulation at BL 48 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation.

Indications and Potential Point Combinations

- **Back pain:** BL 48 if tender, along with other trigger points and BL points related to somatic dysfunction in a spinal segmental manner, accounting for the multisegmental input of nociceptive signals. BL 40, BL 60, and/or ST 36 as strong distal points.
- **Liver and/or gallbladder dysfunction:** BL 48, BL 19, BL 18, GV 24, LR 14, ST 36, LR 3.
- **Jaundice:** BL 48.[4]

BL 49

Yi She "Abode of Thought" or "Reflection Abode"

On the lateral border of the erector spinae muscle column in the 11th (last) intercostal space, shared by BL 20.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (iliocostalis thoracis):** Acting unilaterally, the iliocostalis sidebends the vertebral column; acting bilaterally, it extends the spine.

Clinical Relevance: Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 49 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as visceral in origin. Serratus posterior inferior trigger points produce pain in the BL 47 to BL 51 region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T6-T11 spinal nerves:** Dorsal ramus innervates skin, bones, joints, and erector spinae at this level. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: BL 49 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[1]

The outer Bladder line points echo the impact of points on the inner line by stimulating similar spinal nerves and cord segments.[2] In the case of BL 49, the inner line companion is the Back Shu point for the spleen (BL 20).

Vessels

- **11th posterior intercostal artery:** Arises from the thoracic aorta. Provides branches that supply dorsal ramus of the spinal nerve, spinal cord, vertebral column, back muscles, and skin. Anastomoses anteriorly with the anterior intercostal artery to supply the intercostal muscles, overlying skin, and parietal pleura.
- **11th posterior intercostal vein:** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygous venous system, which conveys venous blood to the superior vena cava. The azygous vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Neuromodulation at BL 49 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation.

Indications and Potential Point Combinations

- **Emotional disturbance, mental fatigue:** BL 49, HT 3, GV 20, ST 36.
- **Abdominal distension, diarrhea, intestinal discomfort:** BL 49, BL 20, BL 21, CV 12, ST 36, SP 6.
- **Back pain:** BL 49 if tender, BL 23, BL 25, GV 4, GB 30, BL 40, BL 60.
- **Vomiting:** BL 49[3], ST 39, PC 6, CV 12.

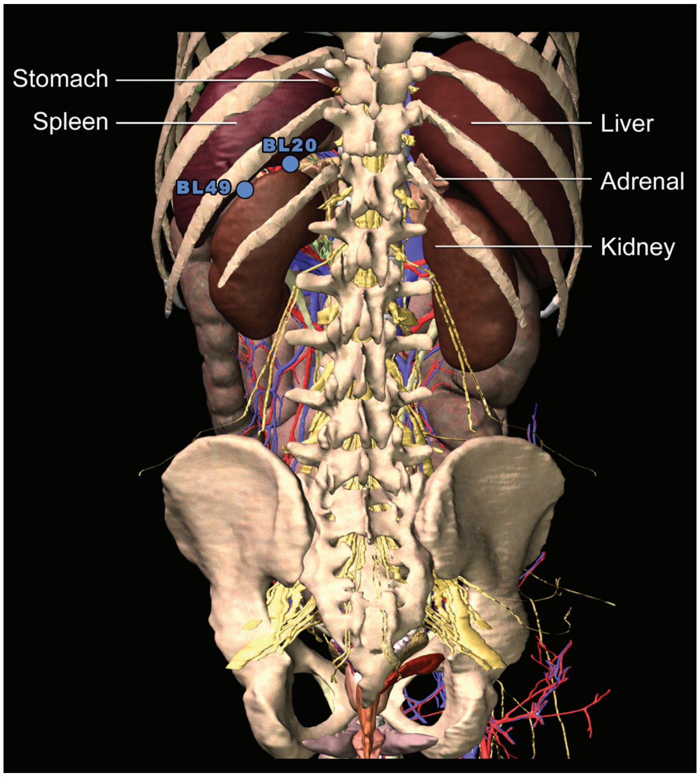

Figure 7-100A. Both BL 49 and BL 20 relate to the horizontal plane of the spleen organ, shown here. As with other outer BL line points, the function of BL 49 pertains to the mental or "psychic" functions affiliated with the organ of the partner Back Shu point. For BL 49, the emotional-mental state assigned to the spleen is "thoughtful reflection", explaining the name, "Abode of Thought" or "Reflection Abode". From a modern medical perspective, patients with splenic disorders may report fatigue and difficulty thinking clearly due to secondary anemia.

BL 50

Wei Cang "Stomach Granary"

On the lateral border of the erector spinae muscle column behind the last rib.

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (iliocostalis):** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 50 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as visceral in origin. Serratus posterior inferior trigger points produce pain in the BL 47 to BL 51 region. Quadratus lumborum trigger points near BL 50 refer pain just lateral and caudal to the iliac crest. Pain may extend to the ventral iliac crest, and inguinal canal, and the caudolateral abdomen. Some pain from a BL 50 trigger point in the quadratus lumborum muscle refers to the ipsilateral sacroiliac region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T7-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.

Clinical Relevance: BL 50 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[1]

The outer Bladder line points echo the impact of points on the inner line by stimulating similar spinal nerves and cord segments.[2] In the case of BL 50, the inner line companion is the Back Shu point for the stomach (BL 21).

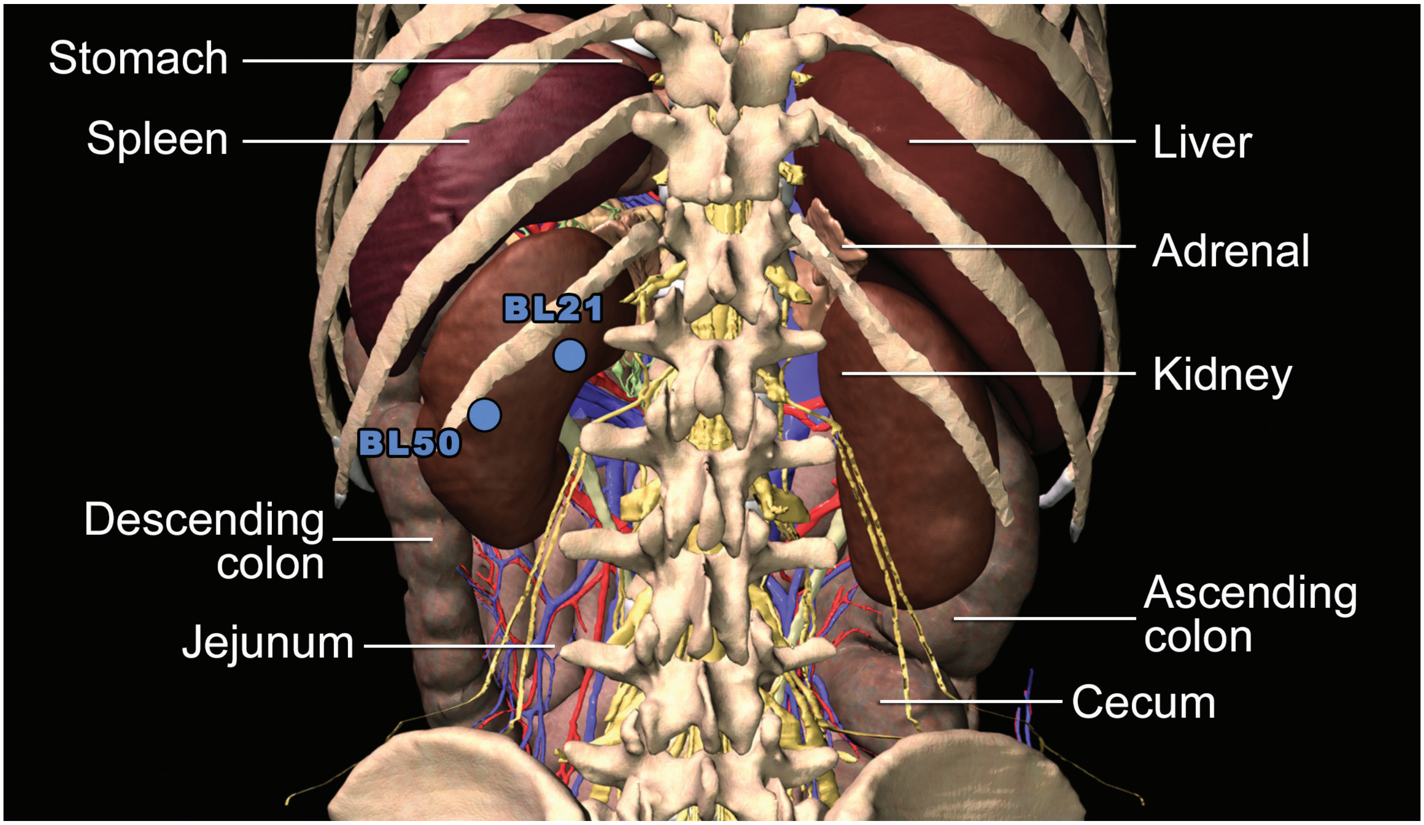

Figure 7-101A. A "granary" stores food, mostly grain, which formed the basis for the Chinese people's subsistence. As the "Stomach Granary", BL 50 acted on food taken in by the stomach. This organ-layer depiction reveals a collection of digestive organs in the vicinity of BL 50 except for the stomach, found several levels up. Neuroanatomically, however, nerves emitted from T12 supply the stomach, supporting a somatovisceral connection.

Figure 7-101B. This image is one of the few cross-sections to display the serratus posterior inferior muscle, albeit appearing here only as a sliver.

Vessels

- **12th posterior intercostal artery (subcostal artery):** Arises from the thoracic aorta. Supplies the muscles of the anterolateral abdominal wall.
- **12th posterior intercostal vein (subcostal vein):** Posterior intercostal veins anastomose with anterior intercostal veins, which are tributaries of the internal thoracic veins. Most posterior intercostal veins terminate in the azygos venous system, which conveys venous blood to the superior vena cava. The azygos vein communicates with the vertebral venous plexuses and the mediastinal, esophageal, and bronchial veins.

Clinical Relevance: Neuromodulation at BL 50 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation.

Indications and Potential Point Combinations

- **Abdominal pain or distension, nausea, vomiting, constipation:** BL 50, BL 21, ST 36, PC 6.
- **Back pain:** BL 50, other points related to the somatic dysfunction in terms of myofascial trigger points, spinal segments supplying the painful region (BL points), GV and Huatuojiaji (1/2 cun from the midline) points for spine-based pain.

BL 51

Huang Men "Vitals Gate"

Below the thoracolumbar junction, at the lateral border of the iliocostalis muscle, level with BL 22 and the caudal aspect of the L1 spinous process.

CAUTION: Avoid deep needling that may injure internal organs.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure.
- **Lumbar interfascial triangle (LIFT):** The LIFT appears in Figure 7-102B. This fat-filled space, situated along the lateral margin of the paraspinal muscles from rib 12 to the iliac crest, forms from the ventral and dorsal laminae of the transversus abdominis and internal oblique aponeurosis where they become continuous with the paraspinal rectal sheath. As such, the LIFT comprises several fascial sheaths that come together at the lateral border of the thoracolumbar fascia. The lateral raphe represents the thickened complex of dense connective tissue formed at this lateral border of the thoracolumbar fascia that contains the LIFT. It occupies the site where the myofascial layers of the abdominal wall meet and join with the paraspinal rectal sheath.[1] This ridged-union juncture of connective tissue brings together fascial contributions from the ventrolateral abdominal wall, the superficial and deep layers of back musculature, and aspects of the gluteal region. Thus, forces tugging on the LIFT from one direction can distribute across several structures, thereby limiting injury to one site. The LIFT may also accommodate lateral expansion of the erector spinae during contraction or act as a fulcrum to distribute tension.
- **Clinical Relevance:** Excess tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[2] The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[3,4]

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Serratus posterior inferior muscle:** By attaching near the angles of the inferior three or four ribs, this muscle depresses the inferior ribs, preventing them from being pulled superiorly by the action of the diaphragm.
- **Erector spinae muscles (iliocostalis, specifically):** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Referred pain from BL 51 that reaches around the trunk could cause diagnostic confusion and cause some to interpret myofascial referred pain as visceral in origin. Serratus posterior inferior trigger points produce pain in the BL 47 to BL 51 region. Quadratus lumborum trigger points near BL 51 refer pain just lateral and caudal to the iliac crest. Pain may extend to the ventral iliac crest, and inguinal canal, and the caudolateral abdomen. Some pain from a BL 51 trigger point in the quadratus lumborum muscle will refer to the ipsilateral sacroiliac region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T8-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus

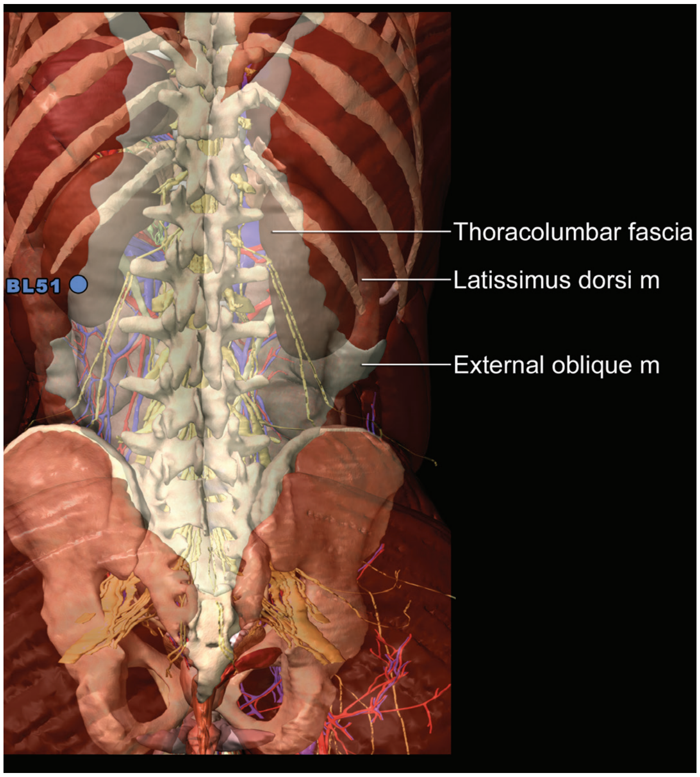

Figure 7-102A. BL 51, "Vitals Gate" describes the low back region ruled by the kidneys, which in Chinese medicine house the vital essence. The kidneys become visible here through the semi-transparent muscle layer.

Figure 7-102B. Note the difference in structures affected by a needle entering BL 51 versus BL 22. Deep to the latissimus dorsi, the lumbar interfascial triangle (LIFT) becomes the next obvious target for BL 51. Treating this region may help dissipate tension held within the various thoracolumbar fascial layers.

provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[5]

Clinical Relevance: BL 51 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[6] Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

The outer Bladder line points echo the impact of points on the inner line by stimulating similar spinal nerves and cord segments.[7] In the case of BL 51, the inner line companion is the Back Shu point for the “triple heater” (BL 22). The endocrine organ associated with this point is the adrenal gland, supplied by T5 through T11.

Vessels

- **1st lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar psoas major muscle, psoas minor muscle, quadratus lumborum muscle, spinal cord and vertebral column, deep back muscles. The first lumbar may give rise to the inferior phrenic or middle suprarenal arteries. On occasion, one of the lumbar arteries provides the gonadal artery. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.
- **1st lumbar vein:** The lumbar veins accompany the lumbar arteries and drain blood from the posterior body wall and the lumbar vertebral venous plexuses. The first and second lumbar veins drain into the ascending lumbar vein. The ascending lumbar veins feed into the azygous venous system. The lumbar veins communicate with the epidural venous plexus within the vertebral column.

Clinical Relevance: Neuromodulation at BL 51 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation. In this case, the organs affected include the adrenal gland and kidney.

Indications and Potential Point Combinations

- **Constipation:** BL 51, BL 52, ST 36.
- **Adrenal problems:** BL 51, BL 22, GV 20.

BL 52

Zhi Shi "Residence of the Will", "Will Chamber", Huang Men "Vitals Gate"

Below the thoracolumbar junction, at the lateral border of the iliocostalis muscle, level with BL 23 and the caudal aspect of the L2 spinous process. Another method of finding BL 52 first requires finding the caudal limit of the costal arch, then moving toward the spine in a perpendicular direction. This finds the L2/L3 interspace. BL 52 is located at the lateral border of the iliocostalis at this level.

CAUTION: Needle carefully to avoid organ puncture.

Connective Tissues

- **Thoracolumbar fascia:** Encloses the deep back muscles. Coordinates actions of the muscles of the back and maintains spinal integrity. Comprises a multi-layered, complex, connective tissue structure.
- **Lumbar interfascial triangle (LIFT):** The LIFT appears in Figure 7-103B. This fat-filled space, situated along the lateral margin of the paraspinal muscles from rib 12 to the iliac crest, forms from the ventral and dorsal laminae of the transversus abdominis and internal oblique aponeurosis where they become continuous with the paraspinal rectal sheath.[3] As such, the LIFT comprises several fascial sheaths that come together at the lateral border of the thoracolumbar fascia. The lateral raphe represents the thickened complex of dense connective tissue formed at this lateral border of the thoracolumbar fascia that contains the LIFT. It occupies the site where the myofascial layers of the abdominal wall meet and join with the paraspinal rectal sheath. This ridged-union juncture of connective tissue brings together fascial contributions from the ventrolateral abdominal wall, the superficial and deep layers of back musculature, and aspects of the gluteal region. As a result, forces tugging on the LIFT from one direction can distribute across several structures, thereby limiting injury to one site. The LIFT may also accommodate lateral expansion of the erector spinae during contraction or act as a fulcrum to distribute tension.

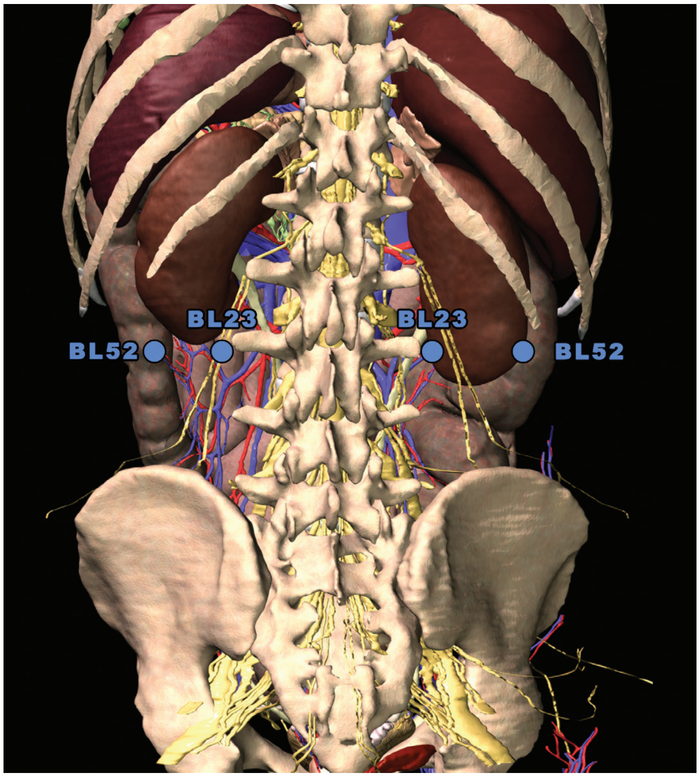

Figure 7-103A. BL 52, "Residence of the Will", speaks to locus of mental-emotional aspects attributed to the kidney that Chinese medicine describe as willpower, decision making, and standing firm for one's convictions. In modern parlance, BL 52 would help someone "have a backbone" when confronting adversaries. Anatomically, BL 52 and its partner, BL 23, enclose the kidneys. The right kidney sits lower than the left due to the presence of the liver.

Clinical Relevance: Excess tension and strain held within the thoracolumbar fascia compresses the structures embraced by it; namely, muscles, nerves, vessels, and lymphatic pathways. Disintegration of thoracolumbar fascial anatomy as can happen with adjacent vertebral segment disease, appears on magnetic resonance imaging as "sagging posterior layer thoracolumbar fascia".[4] The thoracolumbar fascia aids in stabilizing the lumbar spine by modulating forces generated by its various attachments. It may also aid in proprioception of the back through signals sent by its own free nerve endings and mechanoreceptor signals or by means of its connections with the serratus posterior inferior and other muscles conferring information about posture and position of the spine in space.[5,6]

Muscles

- **Latissimus dorsi muscle:** Extends, adducts, medially rotates humerus.
- **Erector spinae muscles (iliocostalis, specifically):** Acting unilaterally, they laterally bend the vertebral column; acting bilaterally, they extend the head and vertebral column.
- **Quadratus lumborum muscle:** Laterally flexes and extends the vertebral column. Stabilizes the 12th rib during inspiration.

Clinical Relevance: Iliocostalis trigger points in this region typically refer along the BL channel, around the trunk in a quasi-dermatomal fashion, or lead to pain on the ventral thorax or abdomen in paramedian locations. Quadratus lumborum trigger points near BL 52 refer pain just lateral and caudal to the iliac crest. Pain may extend to the ventral iliac crest, and inguinal canal, and the caudolateral abdomen. Some pain from a BL 52 trigger point in the quadratus lumborum muscle will refer to the ipsilateral sacroiliac region.

Nerves

- **Thoracodorsal nerve (C6, C7, C8):** Innervates the latissimus dorsi muscle.
- **T8-T11 spinal nerves, plus the T12 spinal nerve (subcostal nerve):** Dorsal ramus innervates skin, bones, joints, muscles of the back. Ventral ramus forms intercostal nerves; rami communicantes connect each intercostal nerve to an ipsilateral sympathetic trunk, from which fibers will travel to regional blood vessels, sweat glands, and smooth muscle.
- **L1 spinal nerve:** Dorsal ramus innervates intrinsic muscles of

Figure 7-103B. The latissimus dorsi muscle and lumbar interfascial triangle (LIFT) are obvious targets for BL 52.

the back and the skin adjacent to the vertebral column. Ventral ramus innervates the psoas muscle. The L1 ventral ramus provides the ilioinguinal and iliohypogastric nerves, which supply the skin of the suprapubic and inguinal regions, the superolateral quadrant of the buttock, and provides branches to the abdominal musculature. L1 is part of the lumbar plexus of nerves (composed of the ventral rami of the L1 through L4 nerves). In combination with L2, L1 gives rise to the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia. Sympathetic fibers that arise from the T12-L1 spinal cord segments course through the hypogastric plexus; ganglia of this plexus play an important role in ejaculation, as T12-L1 supplies innervation to the penis.[7]

- **L2 spinal nerve:** Dorsal ramus innervates intrinsic muscles of the back and the skin adjacent to the vertebral column. L2 (with L3 and L4) give rise to the obturator, femoral, and anterior femoral cutaneous nerves. The obturator nerve supplies the adductor muscles. The femoral nerve innervates the iliacus muscle, as well as the hip flexors and knee extensors. L2 and L1 comprise the genitofemoral nerve, which supplies the skin over the femoral triangle and the scrotum or the labia majora. The anterior femoral cutaneous nerve supplies the skin on the medial and anterior aspects of the thigh. The combination of L2 and L3 produce the lateral femoral cutaneous nerve, which supplies the skin on the anterolateral surface of the thigh. The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.

Clinical Relevance: BL 52 continues the outer BL line on the torso. The difference between the inner and outer BL channel relates to the spinal nerve branches associated with the point. That is, the outer line points associate more closely with the ventral ramus of a given spinal cord segment while the inner line points adhere to the dorsal ramus, lateral branch. These access sites for neuromodulation also represent locations where spinal nerve branches can experience entrapment and lead to back pain as nerves migrating through layers of muscle and blankets of fascia become compressed.[8] Nerves traversing this muscular region run the risk of entrapment and irritation. The risk increases as erector spinae bulk grows in size and strength. Acupuncture, massage, and laser therapy relax the myofascia and free the nerves from their oppressive compression.

The outer Bladder line points echo the impact of points on the inner line by stimulating similar spinal nerves and cord segments.[9] In the case of BL 52, the inner line companion is the Back Shu point for the kidney (BL 23). The kidney receives autonomic fibers from T10-L2; BL 23 and BL 52 live at the L2 dermatome.

Vessels

- **2nd lumbar artery:** One of four or five pairs of arteries that originate in the abdominal aorta and supply the lumbar vertebrae and the back muscles and abdominal wall. On occasion, one of the lumbar arteries provides the gonadal artery. The lumbar arteries supply part of the spinal cord, the vertebral body, and vertebral end plate. The lumbar arteries anastomose with the lower intercostal, the subcostal, the iliolumbar, the deep iliac circumflex, and the inferior epigastric arteries.

- **2nd lumbar vein:** The lumbar veins accompany the lumbar arteries and drain the posterior body wall and the lumbar vertebral venous plexuses. The first and second lumbar veins drain into the ascending lumbar vein. The ascending lumbar veins become the azygous venous system. The lumbar veins communicate with the epidural venous plexus inside the vertebral column.

Clinical Relevance: Neuromodulation at BL 52 may improve circulation to and from structures of the back, frequently afflicted with pain and tension. Acupuncture, laser therapy, and massage benefit blood flow and venous return, which supports soft tissue health and restoration. One can also consider the impact of spinal segmental neuromodulation on circulation to internal organs supplied by the same spinal segments; improving blood flow to and from the associated viscera through sympathetic neuromodulation. In this case, the organs affected include the adrenal gland and kidney.

Indications and Potential Point Combinations

- **Back pain or stiffness:** BL 52, BL 23, GV 4, other trigger points or points related to the somatic dysfunction or spinal segmental facilitation.
- **Lack of willpower and ambition:** BL 52, BL 23, GV 4, ST 36, LI 4, GV 20.
- **Kidney disorders:** BL 52, BL 23, GV 4, BL 22, KI 3.

Evidence-Based Applications

- A case series indicated that point injection at BL 23, BL 24, and BL 52 alleviated or improved **nephritic colic.**[1]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6, plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LI 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[2]

BL 53

Bao Huang “Bladder’s Vital Centers”

On the gluteal region, 3 cun lateral to the midline, level with S2 and the 2nd sacral foramen. Along the same horizontal line as BL 28, BL 32, and the posterior superior iliac spine.[1] Along the same vertical line described by the lateral border of the erector spinae muscle column.

Muscles

- **Gluteus maximus muscle:** Extends the thigh (especially when the thigh is flexed). Assists in lateral rotation of the thigh. Steadies the thigh and helps one rise from a sitting position. Pain from trigger points in the gluteus maximus muscle worsens in cold water and with swimming, earning the muscle the name of “swimmer’s nemesis.”
- **Gluteus medius muscle:** Acts in concert with the gluteus minimus muscle to abduct the thigh. Both muscles serve to support the weight of the body on one limb; in conjunction with the tensor fasciae latae muscle, the gluteus medius and minimus support the position of the pelvis in neutral. With a flexed hip, the gluteus medius and minimus internally rotate the thigh, whereas with an extended hip, they externally rotate it.

Clinical Relevance: A trigger point at or near BL 53 in the gluteus maximus muscle refers pain to the sacroiliac joint and then to the transverse gluteal crease to the hip and proximal thigh. Referred pain from gluteus medius trigger points in the vicinity of BL 53 extends strongly to the dorsal iliac crest to the sacroiliac joint and the general gluteal region. A gluteus medius trigger point on the dorsolateral iliac crest sends pain to the dorsolateral buttock and thigh.

Nerves

- **Superior cluneal nerve (L1-L3):** Supplies the skin of the buttock region.
- **Middle cluneal nerves (S1-S3):** Supplies the skin of the buttock region.
- **Superior gluteal nerve (L4-S1; sometimes includes S2):** Supplies the gluteus medius and minimus muscles. Also innervates the tensor fasciae latae muscle.
- **Inferior gluteal n. (L5-S2):** Innervates the gluteus maximus muscle.

Clinical Relevance: Entrapment of the superior gluteal nerve causes weakness of the gluteus medius and minimus muscles, as well as the tensor fasciae latae muscle. A characteristic gait disturbance follows, known as the Trendelenburg gait. The “positive Trendelenburg sign” occurs during the swing phase of the normal, unsupported limb, in which case the pelvis drops on the side with the injured nerve.

Patients with compression of the superior gluteal nerve typically complain of spontaneous gluteal pain, tenderness to palpation of the cranial gluteal region near the greater sciatic notch, and weakness when abducting the lower limb.[2] Piriformis muscle tension and hypertrophy run the risk of compressing the superior gluteal nerve as it traverses the suprapiriformis canal, leading to superior gluteal neuropathy. While surgical transection of the piriformis muscle has been reported to alleviate symptoms and signs of superior gluteal nerve entrapment, neuromodulation

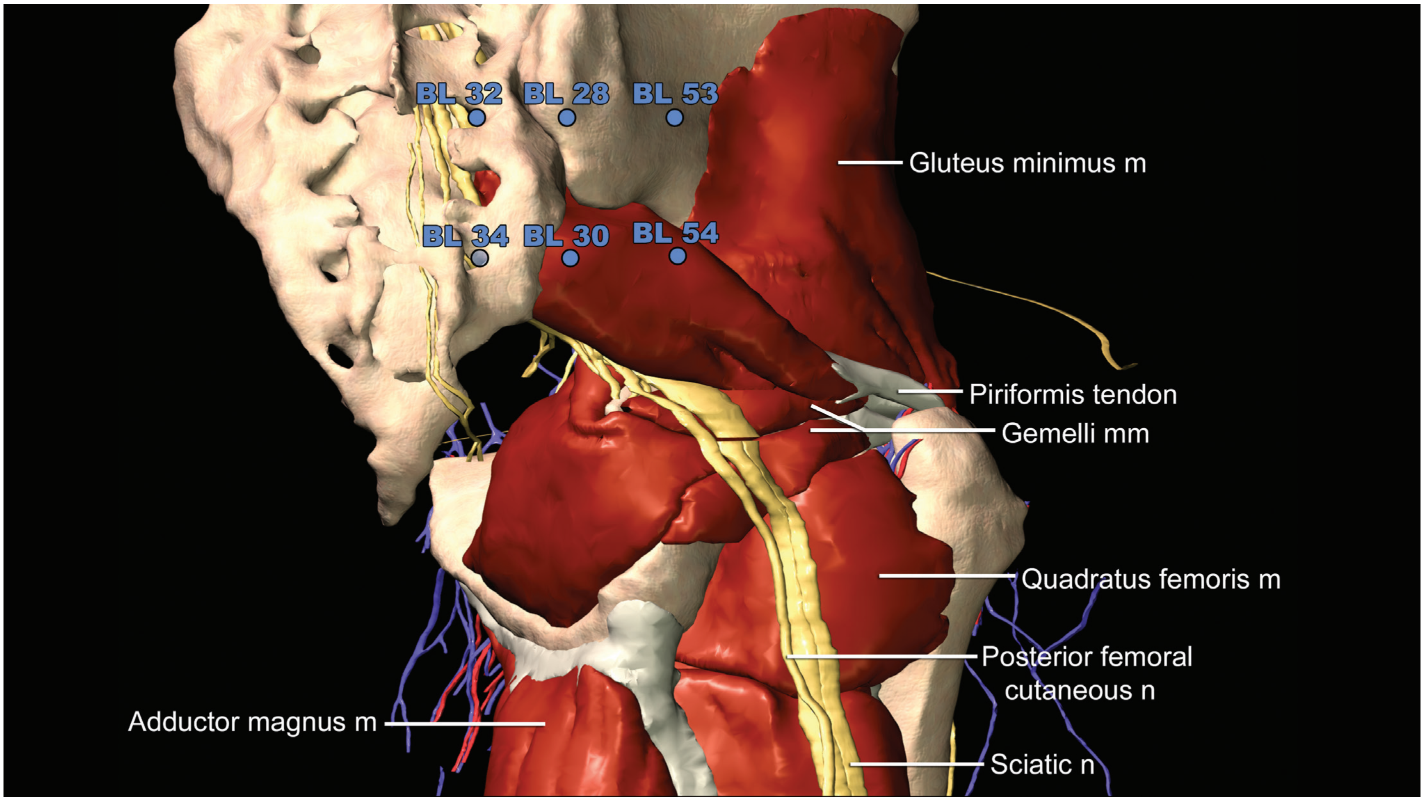

Figure 7-104. BL 53, “Bladder’s Vital Centers” falls along the same horizontal line as two other points that connect with nerve segments affecting bladder function; i.e., BL 28 and BL 32. The neuroanatomic basis for the influence over pelvic organs pertains to the somatovisceral and viscerosomatic reflexes taking place in the spinal segments that supply BL 53, i.e., L1-S2. (Refer to nerve section above or spinal cord segmental origins.)

Figure 7-105. Beneath the large gluteus maximus muscle lurks the gluteus medius, called the "lumbago muscle". This cross section indicates the depth that an acupuncture needs to reach in order to deactivate trigger points in the gluteus medius muscle by way of BL 53.

with acupuncture and related techniques would be a preferred, non-invasive initial approach that allows patients to maintain functionality of muscles affecting hip motion and stabilization by leaving their attachments intact.

Middle cluneal nerve entrapment may cause low back pain, whether due to tension in the erector spinae group compressing the nerves or from gluteus maximus overload. Palpate for trigger points in the gluteus maximus, gluteus medius, and piriformis; deactivate accordingly.

Vessels

- **Superior gluteal artery:** Supplies the gluteus maximus, gluteus medius, and gluteus minimus muscles. Also supplies the tensor fasciae latae m.
- **Superior gluteal vein:** Accompanies the superior gluteal artery. Communicates with femoral vein tributaries to provide an alternate route for blood return from the pelvic limb (leg).

Clinical Relevance: The superior gluteal vessels course with the superior gluteal nerve; the venous network can surround the trunk of the superior gluteal nerve as it exits the pelvis by passing through the greater sciatic notch near BL 54. However, superior gluteal nerve entrapment is more commonly caused by internal iliac artery aneurysm.[3] Another source of vascular compromise involves an aponeurotic arch arising from the sacral attachment of the gluteus and piriformis muscles that may encircle the superficial branches of the superior gluteal artery.

Pelvic and acetabular fractures may injure the superior gluteal artery and its branches.[4] Blunt trauma to the gluteal region while the person sits in an active saddle position is at heightened risk of hemodynamic compromise and injury of the superior gluteal artery. Treatment with acupuncture, soft tissue manual therapy, and laser therapy support circulation, provide analgesia, and promote tissue recovery. As such, they are worthy of consideration early in these cases.

Indications and Potential Point Combinations

- **Painful or restricted hip motion, low back pain, local buttock pain, pain radiating to hip or to thighs and feet:** BL 53, consider piriformis dysfunction and trigger points, gluteus maximus trigger points, BL 54, GB 29, GB 30.
- **Abdominal distension, constipation:** BL 53, check for rectus abdominis trigger points in the KI 12, KI 13, ST 28, ST 29 that radiate in a band-like fashion to the back.
- **Voiding dysfunction:** BL 53, BL 28, BL 32, BL 39, CV 2, CV 3, KI 3, SP 6.

BL 54

Zhi Bian "Sequential Limit"

On the gluteal region, 3 cun lateral to the sacrococcygeal hiatus at the midline, or the 4th sacral foramen.

Directly caudal to BL 53, level with BL 30 and BL 34, as shown in Figure 7-104. BL 54 lands at the intersection of a vertical line described by the lateral border of the erector spinae muscle group and the horizontal line at the S4 foramen and the .

Muscles

- **Gluteus maximus muscle:** Extends the thigh (especially when the thigh is flexed). Assists in lateral rotation of the thigh. Steadies the thigh and helps one rise from a sitting position.
- **Gluteus medius muscle:** Acts in concert with the gluteus minimus muscle to abduct the thigh. Both muscles serve to support the weight of the body on one limb; in conjunction with the tensor fasciae latae muscle, the gluteus medius and minimus support the position of the pelvis in neutral standing. With a flexed hip, the gluteus medius and minimus internally rotate the thigh, whereas with an extended hip, they externally rotate it.
- **Piriformis muscle (superior margin):** Laterally rotates the extended thigh. Abducts the flexed thigh. Steadies the femoral head in the acetabulum. This so-called "double devil" can induce severe pain when shortened not only through its pain projections from myofascial trigger points but also by means of its capacity to entrap the sciatic nerve.

Clinical Relevance: Dry needling of piriformis trigger points can proffer significant relief of myofascial dysfunction in the gluteal region characterized by gluteal pain, sciatic neuropathy, and difficulty walking. Piriformis "syndrome" may mimic lumbosacral intervertebral disk disease signs. Prior to embarking on a surgical correction, it is wise to palpate for a myofascial source of nerve compression through which neuromodulation can alleviate pain and dysfunction without surgery. Piriformis trigger points at BL 54 cause pain strongly in the lateral buttock near the hip, leading to diagnostic confusion between myofascial dysfunction, hip pain/arthritis, and sciatica due to concomitant nerve compression. In 10% of humans, the fibular nerve portion of the sciatic nerve courses through the piriformis muscle, making entrapment even more likely.

Gluteus maximus trigger points near BL 54 may refer pain from the sacroiliac joint to the transverse gluteal crease.

Referred pain from gluteus medius trigger points in the vicinity of BL 54 extends strongly to the dorsal iliac crest to the sacroiliac joint and the general gluteal region. A gluteus medius trigger point on the dorsolateral iliac crest sends pain to the dorsolateral buttock and thigh.

Nerves

- **L1-L2 spinal cord segments:** The L1 and L2 spinal cord segments provide the sympathetic innervation for the remaining lumbar and sacral sympathetic ganglia.
- **Superior cluneal nerve (L1-L3):** Supplies the skin of the buttock region.
- **Middle cluneal nerves (S1-S3):** Supplies the skin of the buttock region.
- **Superior gluteal nerve (L4-S1):** Supplies the gluteus medius and minimus muscles. Also innervates the tensor fasciae latae muscle.
- **Inferior gluteal nerve (L5-S2):** Innervates the gluteus maximus muscle.
- **Sciatic nerve (L4-S3):** Supplies no structures in the gluteal region, but does supply all of the leg and foot muscles, as well as the skin of the posterior thigh, most of the leg, and the skin of the foot. It comprises the tibial and common fibular (or common peroneal) nerves.

Clinical Relevance: Careful, in-depth myofascial palpation of the lumbar region, hip joint and surrounding structures, the sacrum, gluteal regions, and thigh help elucidate the source(s) of referred pain, joint discomfort, and enigmatic sensory changes. The number of nerves coursing through this site as well as the strength and size of the muscle tissue at and around BL 54 predisposes patients to disorders arising from nerve entrapment. Dry needling, soft tissue manual therapy, laser therapy, etc. constitute valuable avenues through which to free the nerves and relax the tissues.

Vessels

- **Inferior gluteal artery:** Supplies the gluteus maximus, obturator internus, and quadratus femoris muscles and the superior portions of the hamstring muscles.
- **Inferior gluteal vein:** Accompanies the inferior gluteal artery. Communicates with femoral vein tributaries to provide an alternate route for blood return from the leg.

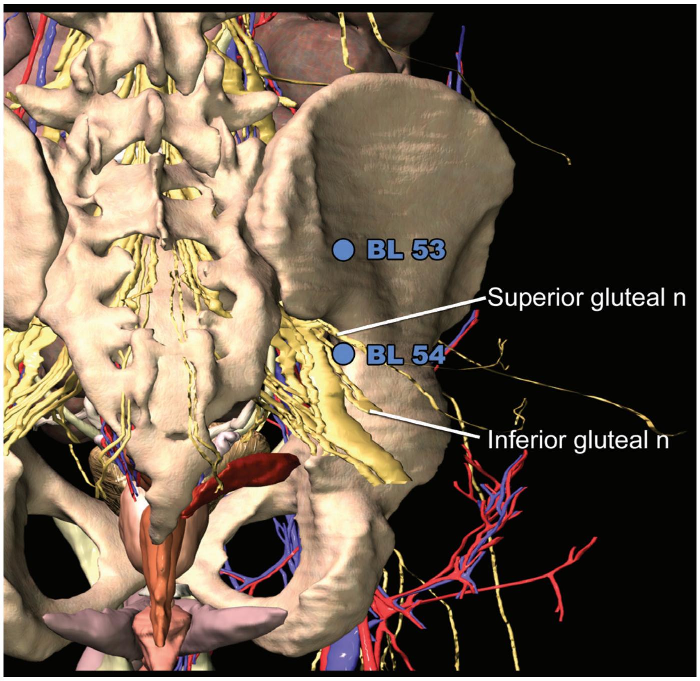

Figure 7-106. As the "Sequential Limit", BL 54 marks the caudal extent of the outer Bladder line. This neurovascular layer details the course of the superior and inferior gluteal nerves, both of which may suffer compression due to myofascial restriction or hypertrophy in the piriformis muscle, shown in Figure 7-104.

Figure 7-107. This cross section illustrates the vulnerability of the superior gluteal and sciatic nerves to entrapment by the piriformis and gluteus maximus muscles. It also exposes the depth at which one needs to treat in order to deactivate trigger point pathology in the piriformis and gluteus medius.

Clinical Relevance: Vascular enlargement (e.g., varicosities, aneurysms, etc.) may induce progressively worsening signs of sciatic nerve entrapment. Pain caused by vascular compression of the sciatic nerve sometimes lessens during ambulation when the varicosities temporarily shrink in size.

Indications and Potential Point Combinations

- **Local buttock pain and hip stiffness, especially in extension:** BL 54, BL 53, BL 27, BL 30, tender trigger points in the region, GB 30, BL 40, KI 10. Also consider GB 31, ST 36, GB 34, GB 39, and BL 60.
- **Coccygeal or sciatic pain:** BL 54, BL 35, GV 2, GV 1.
- **Hemorrhoids:** BL 54, BL 35, GV 1.
- **Cystitis:** BL 54, BL 28, BL 32, CV 3.

Evidence-Based Applications

- Clinical application **(i.e., back pain, leg pain, constipation, or hemorrhoids)** dictates optimal needling direction.[1]
- A case series reported that both acupuncture and moxibustion at BL 23, BL 32, BL 54, SP 6, CV 3, CV 4, KI 12, and LR 3 were effective in treating **erectile dysfunction.**[2]
- Needling and mild moxibustion delivered to BL 23, BL 25, BL 54, CV 3, CV 4, CV 6, SP 6, and ST 28 effectively resolved **chronic prostatitis.**[3]
- Acupuncture to GV 3, GV 4, BL 23, BL 24, BL 25, BL 36, BL 37, BL 40, and BL 54 in older patients with **chronic low back pain** provided improved functional capacity for up to four weeks; patients in the acupuncture group had fewer medication-related side effects compared to the control group.[4]
- Acupuncture to BL 23, BL 25, BL 40, BL 60, and GB 34, plus tender points near BL 31, BL 32, and BL 54 offered significant relief of pain from **chronic low back pain,** even at a 3 month follow-up.[5]

BL 55

He Yang "Confluence of Yang"

On the proximal calf between the medial and lateral heads of the gastrocnemius muscle, 2 cun distal to the popliteal crease (at BL 40), on the line connecting BL 40 and BL 57.

Muscles

- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended, raises the heel during ambulation, and flexes the leg at the knee joint.
- **Soleus muscle:** Plantarflexes the ankle independently of the knee's position, and steadies the leg on the foot.
- **Plantaris muscle:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.
- **Popliteus muscle:** Weakly flexes the knee and "unlocks" it by rotating the femur in a lateral direction atop the tibial plateau. Adheres to the joint capsule of the knee. Considered the "cornerstone stabilizer" of the posterolateral aspect of the knee in conjunction with its tendon, fascicles, and meniscocapsular attachment sites.[1] For the normal, intact lateral meniscus, the popliteus muscle acts as a retractor.[2]

Clinical Relevance: The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to "tennis leg", a calf injury identified by a "snapping" in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[3] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

A soleus trigger point at BL 55 radiates pain distad to BL 57 and proximad to BL 40.

A tibialis posterior trigger point at BL 55 sends pain to the calf at BL 57, then to the calcaneal tendon, the heel, and the bottom of the foot.

Trigger points in the popliteus muscle at or near BL 55 produce pain in the popliteal fossa and caudodistal femur over the medial epicondyle. Neuromodulation applied to structures around the knee such as the popliteus muscle has the potential to improve proprioception and general stability in conjunction with neuromuscular retraining. The popliteus muscle monitors and

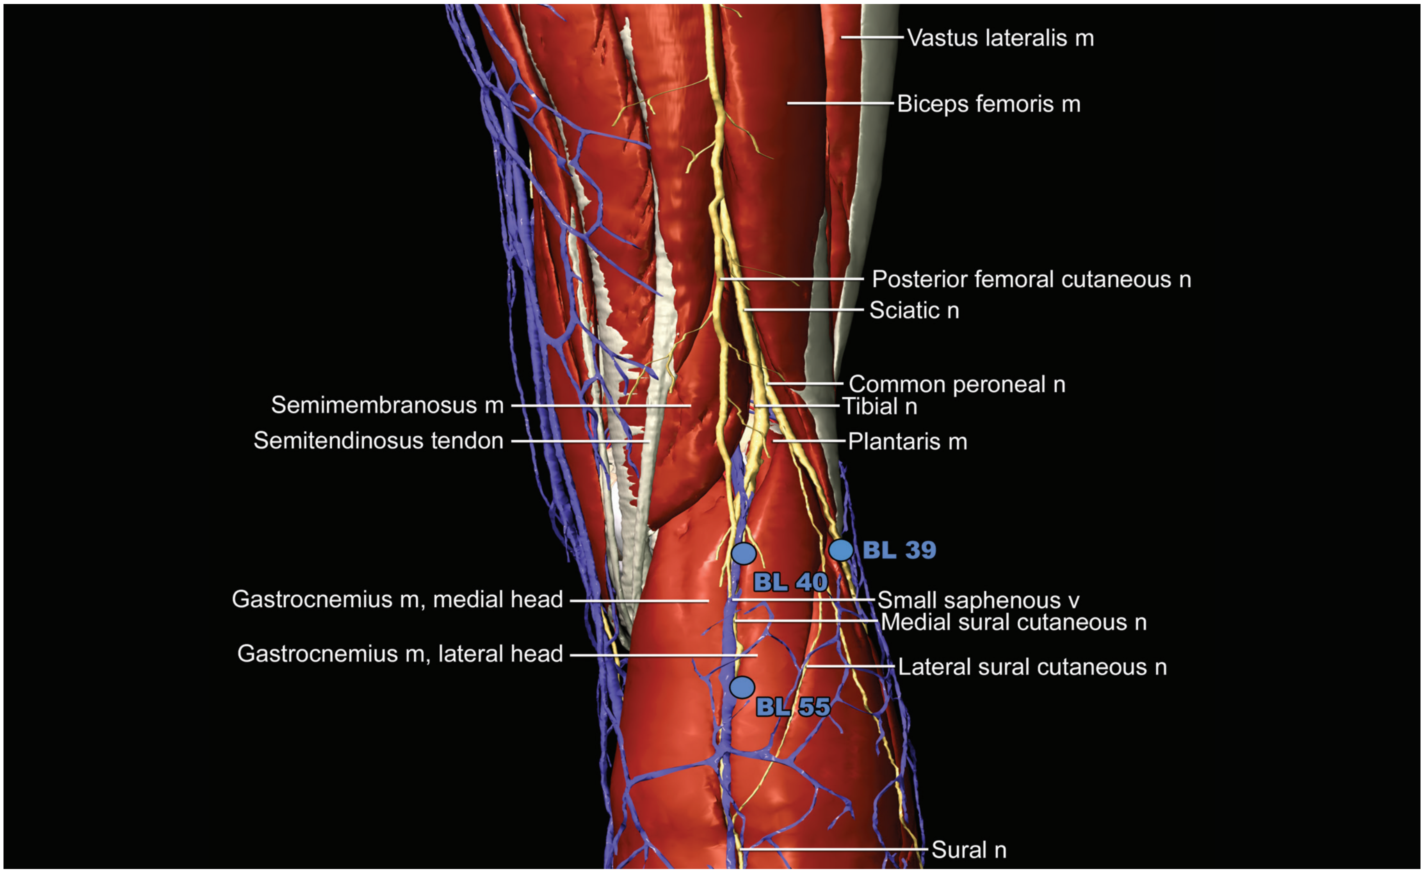

Figure 7-108. The two points, BL 39 and BL 40, representing a divergence of the Bladder channel at the popliteal crease, join together at BL 55, "Yang Union". The term "Yang Union" may also refer to the way in which branches of nerves affiliated with those points blend to form the sural nerve. The sural nerve delineates the neuroanatomic trajectory of the distal BL channel.

controls subtle movements in the knee, tantamount to a three-dimensional dynamic guidance system.[4] The popliteus musculotendinous complex and adjoining structures stabilize the knee by monitoring and controlling tibial external rotation, posterior translation during eccentric function (protecting the posterior cruciate ligament), and by causing tibial internal rotation and posterior translation during concentric function (protecting the anterior cruciate ligament). In short, BL 55 represents an access point through which to influence popliteus function.

Nerves

- **Medial sural cutaneous nerve (S2):** Innervates the skin and subcutaneous tissue of the calf. The medial sural cutaneous nerve arises from the tibial and joins with the ramus communicans of the lateral cutaneous sural nerve from the common fibular nerve.[5]
- **Sural nerve ("short saphenous nerve"):** The sural nerve forms as the union of the medial sural cutaneous nerve from the tibia and the lateral cutaneous sural nerve from the common fibular nerve. It courses between the two heads of the gastrocnemius muscle deep to the crural fascia. At about the junction of the middle and distal thirds of the calf, the nerve exits the fascia to run distad near the small saphenous vein, lateral to the calcaneal tendon and coincident with the BL channel. At this point, the sural nerve anastomoses with the common fibular nerve. It continues on toward the to by passing caudal to the lateral malleolus and the lateral heel and foot, again following the BL channel.
- **Tibial nerve (L4, L5, S1, and S2):** The S1 and S2 branches innervate the plantaris, soleus, and gastrocnemius muscles, while the L4, L5, and S1 branches innervate the popliteus muscle.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). This explains why points such as SP 6 and KI 3 appear more routinely in needling formulae for voiding dysfunction than, for example, BL 40 or BL 55, which would be supplied by more cranial spinal segments that have a less direct relationship with the pelvic organs than do more caudal spinal segments.

Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[6] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[7]

Extrinsic compression of the sural nerve can occur when wearing tight ski boots or a cast on the leg. The crural fascia will, at times, accentuate nerve damage by acting as either a point of compression or fixation, whereupon running or track sports can produce excessive stretch on the tethered nerve.

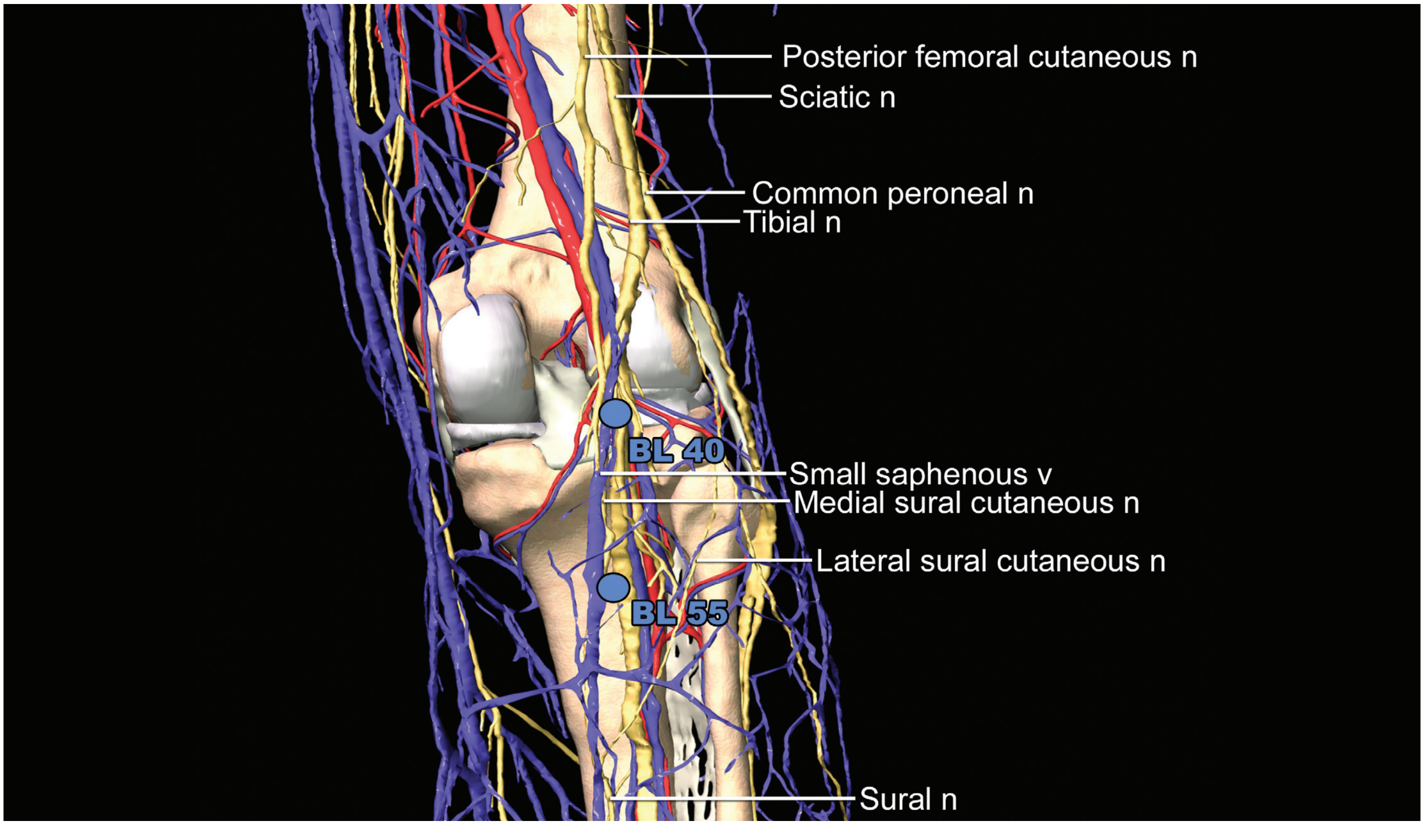

Figure 7-109. BL 55 and BL 40 follow similar neurovascular structures, as shown here.

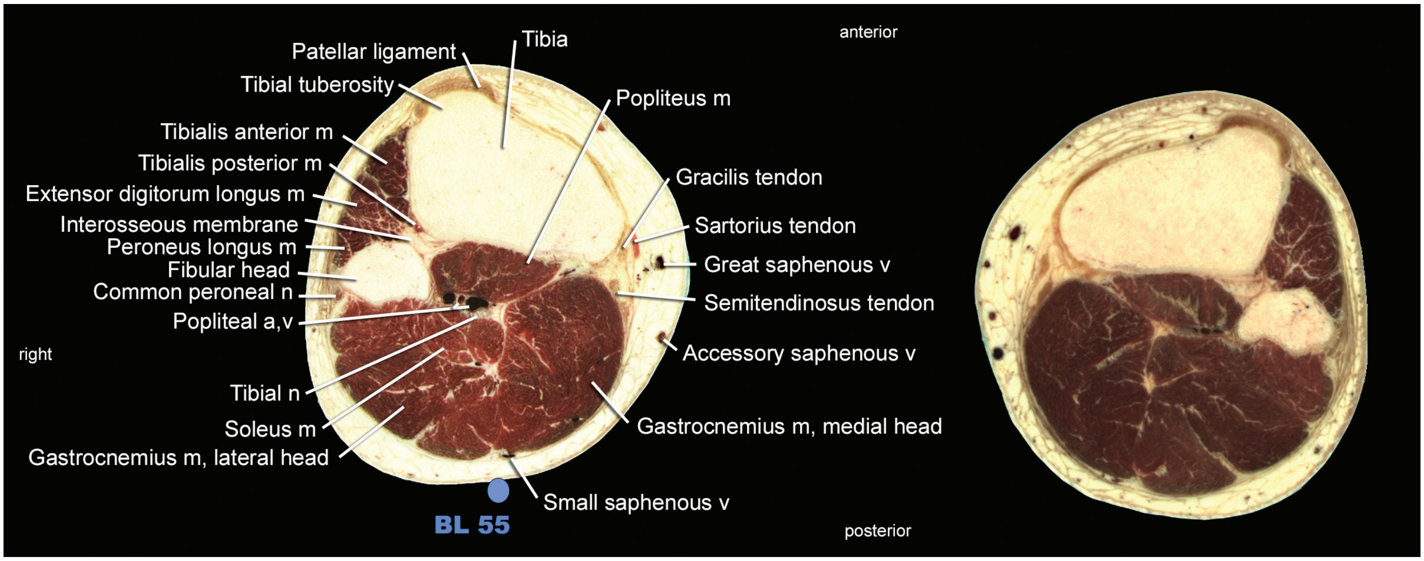

Figure 7-110. The proximity of BL 55 to the small saphenous vein in this cross-section reminds us of the early vascular basis of acupuncture channels, when the intended goal of needling was phlebotomy rather than neuromodulation, even though neuromodulation occurred anyway.

Sports or other activities that predispose a patient to repetitive ankle inversion injury can also cause fibrosis and entrapment of the sural nerve. Patients with sural nerve entrapment report shooting pain or dysesthesia in the distribution of the nerve branch(es) affected. Some confuse the neurogenic pain arising from entrapment with calcaneal tendinopathy; they may be given the diagnosis of recurrent Achilles tendonitis or tears, though the tendon is not the problem.

Vessels

- **Popliteal artery, becoming the anterior and posterior tibial arteries:** The popliteal artery supplies the knee. The anterior tibial artery supplies the anterior compartment of the leg. The posterior tibial artery provides blood to the posterior and lateral compartments of the leg, joins the anastomosis around the knee, and gives off a nutrient artery that passes to the tibia.
- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: Considerable variations exist in the branching of the popliteal artery into its tibial branches. In the same way that fascial bundles and borders entrap nerves, connective tissue structures and anomalous muscles can compress and entrap popliteal vessels and its branches.[8] Acupuncture and related techniques alleviate fascial restriction to improve circulation. Diabetic patients typically develop atherosclerosis in the tibial arteries; this can cause severe critical limb ischemia.[9] Treatment with physical medicine methods aids this patient population as well; laser can be especially beneficial in diabetic circulatory dysfunction.

Indications and Potential Point Combinations

- **Paresis of the pelvic limb:** BL 55, BL 40, BL 36, BL 54, BL 28, BL 23.
- **Lumbar stiffness and pain:** BL 55, BL 40, BL 25, BL 23, GV 4.
- **Gastrocnemius or soleus pain, pain that radiates to the bottom of the foot, mimicking heel spur pain:** BL 55, LR 7, KI 2, other local points.
- **Knee "locking":** The popliteus muscle, the "bent knee trouble-maker", refers pain to the popliteal fossa. The trigger point for this problem lies in the belly of the popliteus muscle, near BL 55.

BL 56

Cheng Jin "Sinew Support" or "Receive the Tendon"

On the caudal calf between the medial and lateral heads of the gastrocnemius muscle, 5 cun distal to the popliteal crease (and BL 40), on a line connecting BL 40 and BL 57. Midway between BL 55 and BL 57.

Muscles and Tendons

- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended, raises the heel during ambulation, and flexes the leg at the knee joint.
- **Soleus muscle:** Plantarflexes the ankle independently of the knee's position, and steadies the leg on the foot.
- **Plantaris tendon:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.

Clinical Relevance: The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to "tennis leg", a calf injury identified by a "snapping" in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[1] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients

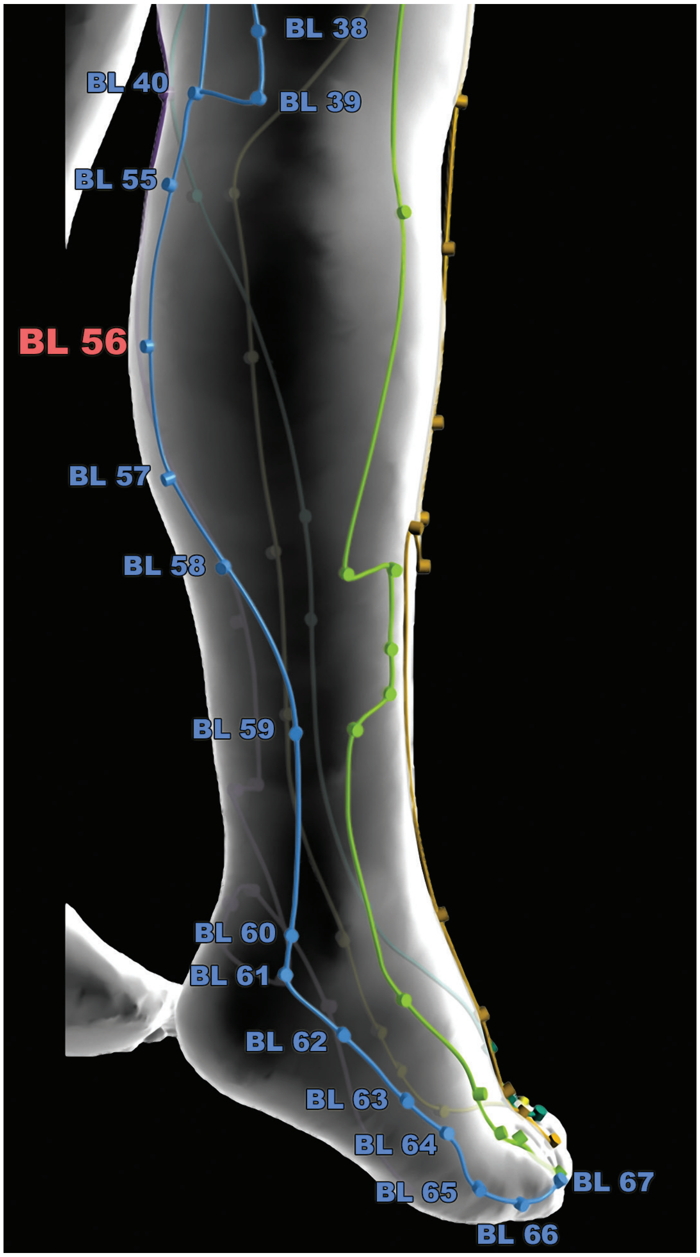

Figure 7-111A. BL 56, "Support the Sinews", lands at a tender spot on the bulge of the calf. The term "sinews" in Chinese medicine encompasses a diverse group of tissues, including fascia, tendons, ligaments, subcutaneous tissue, muscle, joint capsules, and cartilage. This fleshy part of the calf at BL 56 contains many of these tissue types, shown by Figure 7-112 in cross-section.

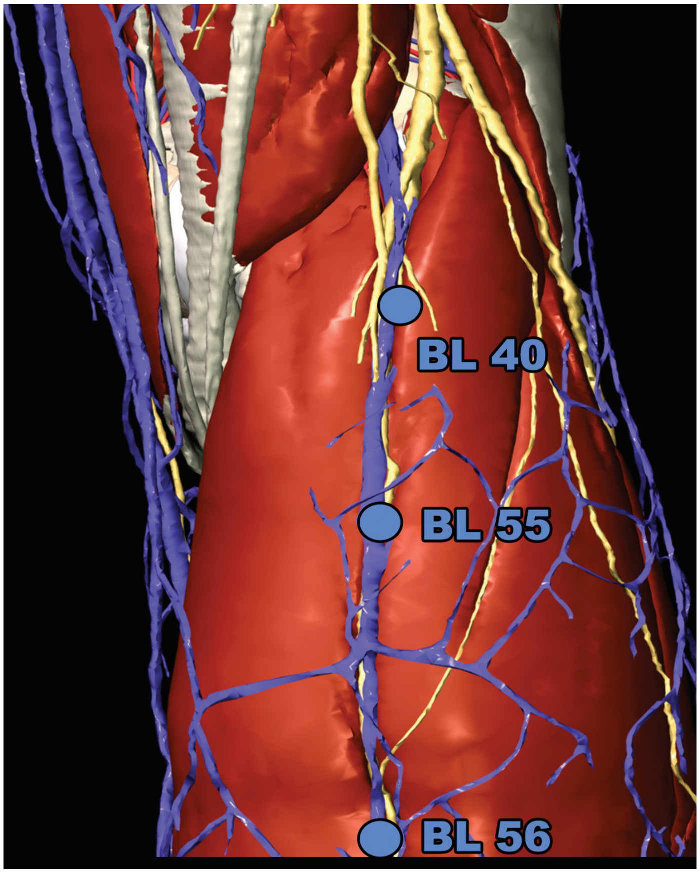

Figure 7-111B. BL 56, "Sinew Support", impacts the triceps surae, defined as the two heads of the gastrocnemius and the soleus muscle. Note how BL 56 lands at the bottom of the biggest part of the bulge in this image. The blue linear structure connecting BL 40, BL 55, and BL 56 is the small saphenous vein, conveniently defining the BL channel trajectory. The yellow nerve fiber coursing beneath the vein is the sural nerve.

maintain the structural integrity of their original design.

A soleus trigger point at BL 56 radiates pain distad to BL 57 and proximad to BL 40.

A tibialis posterior trigger point at BL 56 sends pain to the calf at BL 57, then to the calcaneal tendon, the heel, and the bottom of the foot.

Nerves

- **Medial sural cutaneous nerve (S2):** Innervates the skin and subcutaneous tissue of the calf. The medial sural cutaneous nerve arises from the tibial and joins with the ramus communicans of the lateral cutaneous sural nerve from the common fibular nerve.[2]
- **Sural nerve ("short saphenous nerve"):** The sural nerve forms as the union of the medial sural cutaneous nerve from the tibia and the lateral cutaneous sural nerve from the common fibular nerve. It courses between the two heads of the gastrocnemius muscle deep to the crural fascia. At about the junction of the middle and distal thirds of the calf, the nerve exits the fascia to run distad near the small saphenous vein, lateral to the calcaneal tendon and coincident with the BL channel. At this point, the sural nerve anastomoses with the common fibular nerve. It continues on toward the to by passing caudal to the lateral malleolus and the lateral heel and foot, again following the BL channel. The sural nerve supplies sensation to the skin of the caudal calf, lateral distal leg, and lateral foot.
- **Tibial nerve (S1,S2):** Innervates the soleus and gastrocnemius, as well as all the muscles in the caudal compartment of the leg. muscles.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). This explains why points such as SP 6 and KI 3 appear more routinely in needling formulae for voiding dysfunction than, for example, BL 40 or BL 56, which would be supplied by more cranial spinal segments that have a less direct relationship with the pelvic organs than do more caudal spinal segments.

Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[3] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[4]

Extrinsic compression of the sural nerve can occur when wearing tight ski boots or a cast on the leg. The crural fascia will, at times, accentuate nerve damage by acting as either a point of compression or fixation, whereupon running or track sports can produce excessive stretch on the tethered nerve. Sports or other activities that predispose a patient to repetitive ankle inversion injury can also cause fibrosis and entrapment of the sural nerve. Patients with sural nerve entrapment report shooting pain or dysesthesia in the distribution of the nerve branch(es) affected. Some confuse the neurogenic pain arising from entrapment with calcaneal tendinopathy; they may be given the diagnosis of recurrent Achilles tendonitis or tears, though the tendon is not the problem.

Vessels

- **Posterior tibial artery:** The posterior tibial artery provides blood to the posterior and lateral compartments of the leg, joins the anastomosis around the knee, and gives off a nutrient artery that passes to the tibia.
- **Fibular (peroneal) artery:** The largest and most important branch of the posterior tibial artery, it supplies the muscles in the posterior and lateral leg compartments. It also provides a

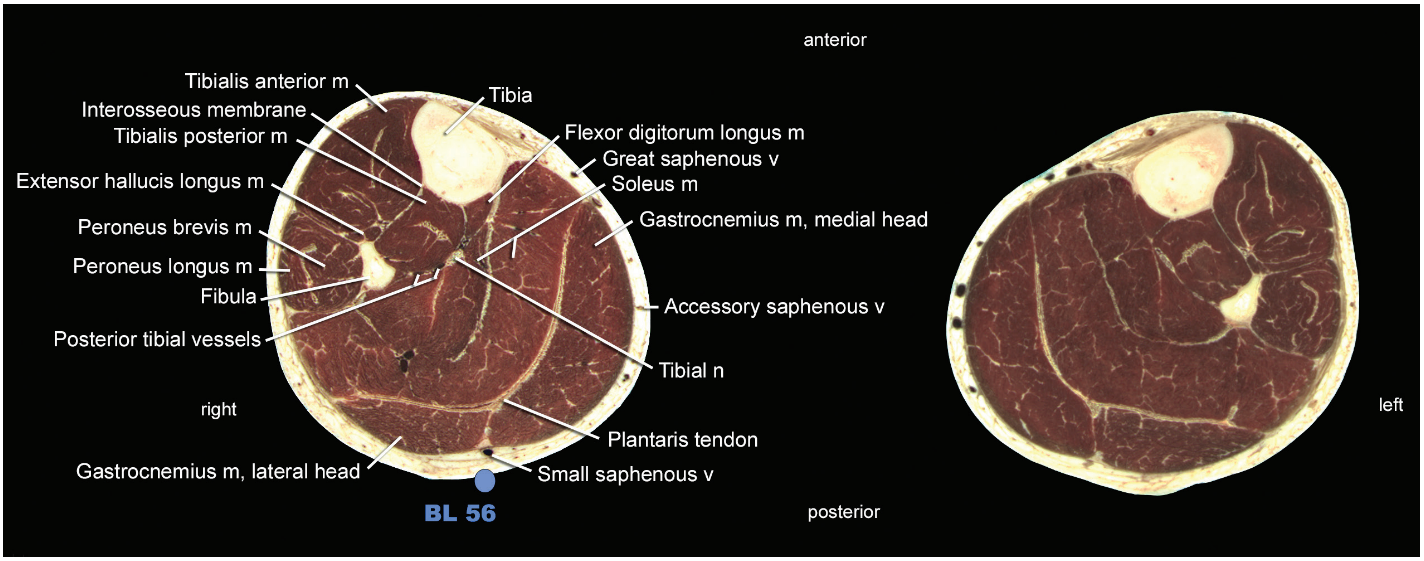

Figure 7-112. BL 56 describes a site on the leg rich with trigger points (in the gastrocnemius and soleus) that can cause local pain as well as discomfort referred proximad to the ipsilateral sacroiliac joint or distad to the heel.

nutrient artery to the fibula. Most often, it pierces the interosseous membrane and passes to the dorsum of the foot, forming an anastomosis with the arcuate artery.

- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: The small saphenous vein, if visible, serves as a landmark for palpating the plantaris tendon, in the event of traumatic injury to the plantaris (see Figure 7-112). The vein also provides a target for estimating the location of the sural nerve, as indicated in Figure 7-111B, where the small saphenous vein and sural nerve both describe the course of the BL channel on the caudal calf.

Indications and Potential Point Combinations

- **Leg and calf pain:** BL 56, BL 55, BL 58, BL 60, KI 3.
- **Lumbar or lumbosacral stiffness and pain:** BL 56, BL 32, BL 27, BL 23.
- **Hemorrhoids:** BL 56, GV 1, GV 2.

BL 57

Cheng Shan "Support the Mountain"

On the posterior surface of the leg, in the depression formed by the lower limit of the two bellies of the flexed gastrocnemius muscle, at the musculotendinous junction. Approximately 8 cun distal to BL 40 at the popliteal crease; midway between BL 40 and BL 60. Locate by running a finger in a proximal direction from the Achilles tendon along the midline of the crus, until it enters a depression between the two bellies of the gastrocnemius muscle.

Muscles and Tendons

- **Gastrocnemius muscle:** Plantarflexes the ankle when the knee is extended, raises the heel during ambulation, and flexes the leg at the knee joint.
- **Soleus muscle:** Plantarflexes the ankle independently of the knee's position, and steadies the leg on the foot.
- **Plantaris tendon:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle.

Clinical Relevance: The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to "tennis leg", a calf injury identified by a "snapping" in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[6] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

A soleus muscle trigger point at BL 57 may radiate pain to the ipsilateral sacroiliac joint.

Nerves

- **Medial sural cutaneous nerve (S1, S2):** Innervates the skin on the posterior and lateral leg and lateral side of the foot; forms the sural nerve if it joins with the lateral sural cutaneous nerve. Accompanies the small saphenous vein.
- **Sural nerve ("short saphenous nerve"):** The sural nerve forms as the union of the medial sural cutaneous nerve from the tibia and the lateral cutaneous sural nerve from the common fibular nerve. It courses between the two heads of the gastrocnemius muscle deep to the crural fascia. At about the junction of the middle and distal thirds of the calf, the nerve exits the fascia to run distad near the small saphenous vein, lateral to the calcaneal tendon and coincident with the BL channel. At this point, the sural nerve anastomoses with the common fibular nerve. It continues on toward the to by passing caudal to the lateral malleolus and the lateral heel and foot, again following the BL channel. The sural nerve supplies sensation to the skin of the caudal calf, lateral distal leg, and lateral foot.
- **Tibial nerve (L4, L5, S1-S3):** Innervates the soleus and gastrocnemius, as well as all the muscles in the caudal compartment of the leg.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). This explains why points such as SP 6 and KI 3 appear more routinely in needling formulae for voiding dysfunction than, for example, BL 40 or BL 57, which would be supplied by more cranial spinal segments that have a less direct relationship with the pelvic organs than do more caudal spinal segments. However, note as well that the cross-section appearing in Figure 7-114 indicates the growing prominence of the flexor hallucis longus, supplied by S2 and S3, the most caudal spinal segments comprising the tibial nerve. This lends insight into the association of BL 57 with rectal disorders such as hemorrhoids and rectal hypersensitivity.

atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[7] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[8] Small saphenous vein stripping can also damage the fibular nerve, though less commonly because of its depth.[9]

Extrinsic compression of the sural nerve can occur when wearing tight ski boots or a cast on the leg. The crural fascia will, at times, accentuate nerve damage by acting as either a point of compression or fixation, whereupon running or track sports can produce excessive stretch on the tethered nerve. Sports or other activities that predispose a patient to repetitive ankle inversion injury can also cause fibrosis and entrapment of the sural nerve. Patients with sural nerve entrapment report shooting pain or dysesthesia in the distribution of the nerve branch(es) affected. Some confuse the neurogenic pain arising from entrapment with calcaneal tendinopathy; they may be given the diagnosis of recurrent Achilles tendonitis or tears, though the tendon is not the problem.

Vessels

- **Posterior tibial artery:** The posterior tibial artery provides blood to the posterior and lateral compartments of the leg, joins the anastomosis around the knee, and gives off a nutrient artery that passes to the tibia.
- **Fibular (peroneal) artery:** The largest and most important branch of the posterior tibial artery, it supplies the muscles in the posterior and lateral leg compartments. It also provides a nutrient artery to the fibula. Most often, it pierces the interosseous membrane and passes to the dorsum of the foot, forming an anastomosis with the arcuate artery.
- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: The small saphenous vein, if visible, serves as a landmark for palpating the plantaris tendon, in the event of traumatic injury to the plantaris (see Figure 7-114). However, as this image indicates, the plantaris tendon is moving mediad in relation to the small saphenous vein, whereas at BL 56, the tendon lies deep to the point. The vein also provides a target for estimating the location of the sural nerve, as indicated in Figure 7-113, where the small saphenous vein and sural nerve both describe the course of the BL channel on the caudal calf.

Indications and Potential Point Combinations

- **Kidney or lumbar pain:** BL 57, BL 23, BL 52, GV 4.
- **Constipation:** BL 57, ST 36.
- **Anal stricture, rectal prolapse, hemorrhoids:** BL 57, BL 54, GV 2, GV 1.[10]
- **Calf cramps:** BL 57, BL 55, BL 56, KI 3, BL 60.
- **Restless legs syndrome:** BL 57, LR 3.[11]
- **Knee pain:** BL 57, in addition to ST 34, ST 36, SP 10, Xiyan (Eyes of the Knee), SP 9, and BL 40.[12]
- **Face and jaw pain:** BL 57 as a trigger point in the soleus muscle. Travell & Simons describe a "rare trigger point" in the ipsilateral soleus muscle that refers pain to the face and jaw.

This argues for the neuroreflexive connection between the distal pelvic limb and the trigeminal nerve, perhaps serving as an evolutionary historic means of coordinating running while keeping prey in the mouth.[1]

Evidence-Based Applications

- Electroacupuncture at BL 40 and BL 57 relieved local ankle spasticity in a child with mild spastic hemiplegic **cerebral palsy.**[2]
- Transcutaneous electrical nerve stimulation (TENS) at LI 4, LU 10, BL 57, and ST 36 effectively reduced rectal hypersensitivity in diarrhea-predominant **irritable bowel syndrome.**[3]
- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[4]
- Electroacupuncture at ST 36 + SP 6 was compared to GB 34

+ BL 57, in order to study differences in **brain activation** from acupuncture points located in the same spinal segments. Both overlapping and distinct cerebral response patterns from stimulation of the two pairs were observed. Both pairs of points (ST 36/SP 6 and GB 34/BL 57) activated the primary and secondary somatosensory areas, insula, ventral thalamus, parietal Brodmann Area 40, temporal lobe, putamen, and cerebellum; both deactivated the amygdala. However, ST 36/SP 6 specifically activated the orbital frontal cortex and deactivated the hippocampus, while GB 34/BL 57 activated the dorsal thalamus and inhibited the primary motor area and premotor cortex. These cerebral response differences may help explain why ST 36/SP 6 is indicated more for visceral disorders and pain while GB 34/BL 57 are important points for modulation of muscle and tendon function and motor output.[5]

BL 58

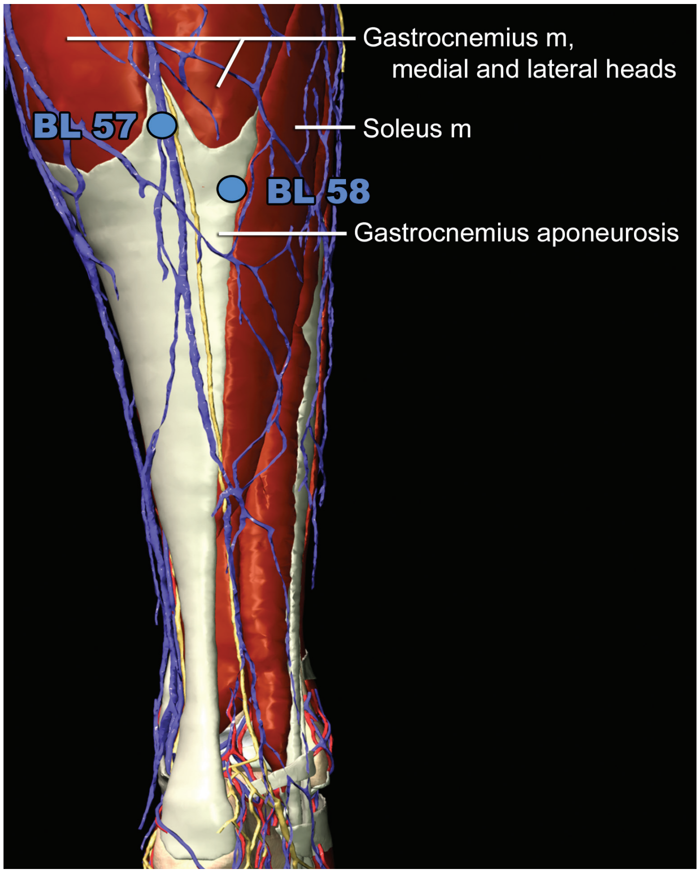
Fei Yang "Soaring Upward" or "Taking Flight"

Between the caudal border of the fibula and the aponeurosis of the gastrocnemius muscle, 7 cun proximal to the lateral malleolus (and BL 60), approximately 1 cun distal and lateral to BL 57.

Muscles

- **Soleus muscle:** Plantarflexes the ankle, independent of the knee's position, and steadies the leg on the foot.
- **Flexor hallucis longus muscle:** Flexes the great toe. Weakly plantarflexes the ankle. Supports the longitudinal arches of the foot.

Clinical Relevance: A soleus muscle trigger point at BL 58 may radiate pain to the ipsilateral sacroiliac joint. Trigger point pathology in the flexor hallucis longus muscle at BL 58 radiates strongly to the plantar aspect of the distal 1st metatarsal and the hallux, or big toe.



Gastrocnemius m, medial and lateral heads
BL 57
Soleus m
BL 58
Gastrocnemius aponeurosis

Figure 7-115. BL 58, "Soaring Upward" lands at a site on the caudal calf where muscle activation would support jumping upward. The thick fascial layer at this level along with the indications for distal BL points related to cephalalgia (headache) cause one to consider the role of fascial fixations between the forehead and the feet that follow this trajectory. That is, in addition to its neuromodulatory actions on the brain, spinal cord, and autonomic nervous system, treatment of distal BL points release tension in the fascia that might be triggering pain in neck and head connections.

Nerves

- **Lateral sural cutaneous nerve:** Supplies the skin and subcutaneous tissue on the lateral calf from the proximal knee to the distal-midcalf region.
- **Sural nerve ("short saphenous nerve"):** The sural nerve forms as the union of the medial sural cutaneous nerve from the tibia and the lateral cutaneous sural nerve from the common fibular nerve. It courses between the two heads of the gastrocnemius muscle deep to the crural fascia. At about the junction of the middle and distal thirds of the calf, the nerve exits the fascia to run distad near the small saphenous vein, lateral to the calcaneal tendon and coincident with the BL channel. At this point, the sural nerve anastomoses with the common fibular nerve. It continues on toward the to by passing caudal to the lateral malleolus and the lateral heel and foot, again following the BL channel. The sural nerve supplies sensation to the skin of the caudal calf, lateral distal leg, and lateral foot.
- **Tibial nerve (L4, L5, S1-S3):** Innervates the soleus and gastrocnemius, as well as all the muscles in the caudal compartment of the leg.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus.

Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[1] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[2] Small saphenous vein stripping can also damage the fibular nerve, though less commonly because of its depth.[3]

Extrinsic compression of the sural nerve can occur when wearing tight ski boots or a cast on the leg. The crural fascia will, at times, accentuate nerve damage by acting as either a point of compression or fixation, whereupon running or track sports can produce excessive stretch on the tethered nerve. Sports or other activities that predispose a patient to repetitive ankle inversion injury can also cause fibrosis and entrapment of the sural nerve. Patients with sural nerve entrapment report shooting pain or dysesthesia in the distribution of the nerve branch(es) affected. Some confuse the neurogenic pain arising from entrapment with calcaneal tendinopathy; they may be given the diagnosis of recurrent Achilles tendonitis or tears, though the tendon is not the problem.

Vessels

- **Fibular (peroneal) artery:** The largest and most important branch of the posterior tibial artery, it supplies the muscles in the posterior and lateral leg compartments. It also provides a nutrient artery to the fibula. Most often, it pierces the interosseous membrane and passes to the dorsum of the foot, forming an anastomosis with the arcuate artery.

Figure 7-116. With BL 58, the BL channel has now moved off the midline of the calf, venturing toward the lateral aspect of the distal pelvic limb toward its destination of the little toe.

- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: Damage to the local neurovascular supply during venous stripping or other surgical approaches warrant consideration of neuromodulation and support of tissue restoration by means of acupuncture and related techniques.

Indications and Potential Point Combinations

- **Headache, dizziness:** BL 58, BL 10, GB 20, LR 3, LI 4.
- **Muscle stiffness:** BL 58, GB 34.
- **Back pain:** BL 58, back pain trigger points, BL paraspinal points and GV points as indicated by palpation exam, affected spinal segments, nature or origin of pain.
- **Leg pain, numbness, or weakness:** BL 58. Identify source of pain, involvement of neuropathic nerves, distribution of pain according to neurologic involvement and myofascial trigger points. For sciatic involvement, consider adding BL 24, BL 25, BL 26, BL 53, BL 54, BL 40, KI 3.

BL 59

Fu Yang “Instep Yang”

Proximal to the ankle, between the Achilles and peroneus brevis muscle (see Figure 7-118). 3 cun superior to BL 60, or the most prominent point of the lateral malleolus.

Tendons

- **Calcaneal (Achilles) tendon:** The common tendon of the “triceps surae” muscle, which includes the two-headed gastrocnemius muscle and the soleus muscle.

Clinical Relevance: Calcaneal tendon rupture can become a recurring problem because the tendinous tissue has a high degree of disorganization. Pulsed low level laser therapy remodels tissue and improves tendon healing by increasing matrix metalloproteinase activity and collagen synthesis.[1] Quinolones may also injure the calcaneal tendon, perhaps through ischemic processes, oxidative damage, and direct collagen toxicity.[2] Patients with calcaneal tendinopathy exhibit pain, swelling, and possibly crepitus at the tendon, at or between BL 59 and BL 60.[3] Acupuncture improves blood circulation and healing to the tendon through systemic/generalized effects.[4]

Muscles

- **Flexor hallucis longus muscle:** Flexes the great toe at all joints. Weakly plantarflexes the ankle. Also, supports the medial longitudinal pedal arches.
- **Peroneus (Fibularis) brevis muscle:** Plantarflexes and everts the foot.

Clinical Relevance: Patients with flexor hallucis longus tendinopathy have pain and swelling over the caudomedial ankle, distal to BL 59. Dancers (ballet) and athletes who repeatedly use the push-off maneuver risk developing flexor hallucis longus tendinopathy. They may complain of pain with resistive flexion of the great toe. Peroneal (fibular) tendinopathy produces pain and swelling caudal to the lateral malleolus. Pain worsens with active eversion and resistive dorsiflexion. Peroneal tendinopathy can follow or co-occur with chronic lateral ankle pain and instability. Trigger point pathology in the peroneal muscles and tendons accentuate instability of the ankle, as they contribute to active stabilization of the joint.[5] Peroneus brevis and calcaneal tendon injuries are frequently encountered in patients who practice yoga.[6]

Nerves

- **Lateral sural cutaneous nerve:** Supplies the skin and subcutaneous tissue on the lateral calf from the proximal knee to the

Figure 7-117. The “instep” in “Instep Yang” refers to the “Yang” component of the metatarsus, i.e., its dorsolateral aspect, where trigger points from the fibularis (peroneus) brevis muscle refer pain.

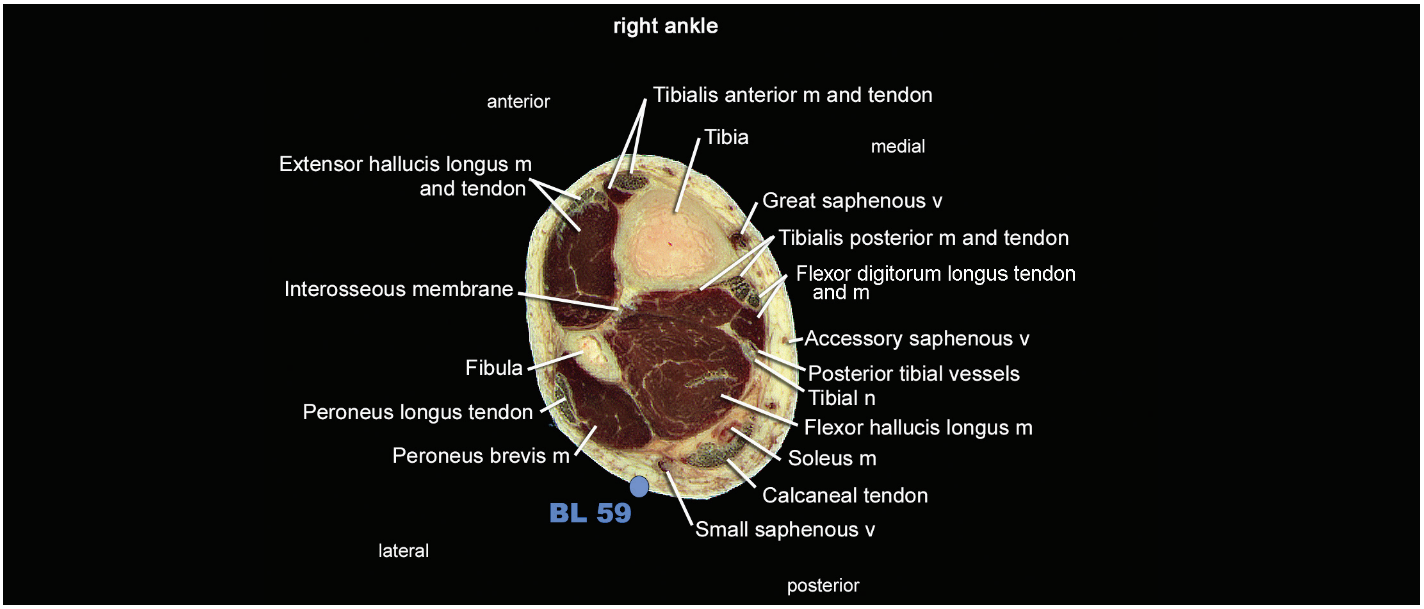

Figure 7-118. This cross-section illustrates how needling can affect structures innervated by both the fibular and tibial nerves, depending on angle and depth of needling. BL 59 also provides access to trigger points in the peroneus brevis and flexor hallucis longus muscles.. This could impact the ankle-stabilizing capacity of both muscles.

distal-midcalf region.

- **Sural nerve ("short saphenous nerve"):** The sural nerve forms as the union of the medial sural cutaneous nerve from the tibia and the lateral cutaneous sural nerve from the common fibular nerve. It courses between the two heads of the gastrocnemius muscle deep to the crural fascia. At about the junction of the middle and distal thirds of the calf, the nerve exits the fascia to run distad near the small saphenous vein, lateral to the calcaneal tendon and coincident with the BL channel. At this point, the sural nerve anastomoses with the common fibular nerve. It continues on toward the to by passing caudal to the lateral malleolus and the lateral heel and foot, again following the BL channel. The sural nerve supplies sensation to the skin of the caudal calf, lateral distal leg, and lateral foot.
- **Tibial nerve (L4, L5, S1-S3):** Supplies all the muscles in the caudal compartment of the leg.
- **Superficial peroneal (fibular) nerve:** Supplies the peroneal (fibularis) longus and brevis muscles, as well as the skin over most of the dorsum of the pes (foot) aside from the area inhabited by LR 2 and LR 3, innervated by the deep peroneal (fibular) nerve.

Clinical Relevance: The intimate relationship between the sural nerve and saphenous vein continues at BL 59. In addition, Figure 7-118 shows the proximity of this neurovascular pairing to the calcaneal tendon. Surgical repair of the tendon may damage the sural nerve.[7]

Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Depending on the tibial nerve branch affected, neuromodulation of the tibial nerve may confer differential effects on somatovisceral reflexes.

Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Post-saphenectomy in cases of saphenous vein stripping or endovenous thermal ablation may cause problems in the nerves coursing through the popliteal fossa such as the sural nerve.[8] The overlapping territory shared by both the small saphenous vein and the sural nerve describe much of the course of the BL channel on the leg.[9] Small saphenous vein stripping can also damage the fibular nerve, though less commonly because of its depth.[10]

Extrinsic compression of the sural nerve can occur when wearing tight ski boots or a cast on the leg. The crural fascia will, at times, accentuate nerve damage by acting as either a point of compression or fixation, whereupon running or track sports can produce excessive stretch on the tethered nerve. Sports or other activities that predispose a patient to repetitive ankle inversion injury can also cause fibrosis and entrapment of the sural nerve. Patients with sural nerve entrapment report shooting pain or dysesthesia in the distribution of the nerve branch(es) affected. Some confuse the neurogenic pain arising from entrapment with calcaneal tendinopathy; they may be given the diagnosis of recurrent Achilles tendonitis or tears, though the tendon is not the problem.

The superficial peroneal (fibular) nerve pierces the deep fascia in the distal leg, emerging to supply the fibular muscles and skin of the craniolateral crus, ankle, and foot. Entrapments or other sources of compression can cause pain, muscular dysfunction, and sensory impairments.

Vessels

- **Fibular (peroneal) artery:** The largest and most important branch of the posterior tibial artery, it supplies the muscles in the posterior and lateral leg compartments. It also provides a nutrient artery to the fibula. Most often, it pierces the interosseous membrane and passes to the dorsum of the foot, forming an anastomosis with the arcuate artery.

- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: Damage to the local neurovascular supply during venous stripping or other surgical approaches warrant consideration of neuromodulation and support of tissue restoration by means of acupuncture and related techniques.

After calcaneal tendon injury, acupuncture and hyperthermia may improve microcirculation in local vessels supplying the tendon whose blood flow promotes repair and recovery of function.[11,12]

Indications and Potential Point Combinations

- **Heaviness in the head, headache:** BL 59, isolate source and trajectory of head discomfort. For occipitofrontalis pain, add BL 10, GV 20.
- **Pain in kidney region:** BL 59, ST 36, SP 6, KI 3, BL 23, BL 52.
- **Acute lumbar sprain:** BL 59[13]
- **Edema of the lateral malleolar area:** BL 59, ST 40, SP 6, SP 7, SP 10.
- **Heel pain:** BL 59, check for peroneus tertius trigger point as well near GB 39 that may cause pain to refer to the lateral heel.
- **Ankle weakness:** BL 59, KI 7.

BL 60

Kun Lun "Kunlun Mountains"

On the lateral ankle, in a depression midway between the most prominent point of the lateral malleolus and the caudal border of the calcaneal tendon.

Nerves

- **Sural nerve:** Arises from the tibial and common fibular nerves (usually). Supplies the skin on the caudal and lateral aspects of the leg as well asthe lateral foot.
- **Tibial nerve (L4, L5, S1-S3):** Supplies all the muscles in the caudal compartment of the leg and the calcaneal tendon.

Clinical Relevance: In addition to neuromodulating somatic nerve activities, acupuncture and related techniques influence autonomic fibers traversing with those nerves. Sympathetic fibers reach their destination by way of both nerves and vessels, not only in the foot, but elsewhere as well, such as the head and neck. Because the foot contains extensive sympathetic nerve supply[7], numerous opportunities for both local and systemic autonomic neuromodulation exist, helping to explain the value of points such as BL 60, LR 3, KI 1, ST 45, and more for distant and homeostatic effects.

Vessels

- **Fibular (peroneal) artery:** The largest and most important branch of the posterior tibial artery, it supplies the muscles in the posterior and lateral leg compartments. It also provides a nutrient artery to the fibula. Most often, it pierces the interosseous membrane and passes to the dorsum of the foot, forming an anastomosis with the arcuate artery.
- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: Damage to the local neurovascular supply during venous stripping or other surgical approaches warrant consideration of neuromodulation and support of tissue restoration by means of acupuncture and related techniques.

After calcaneal tendon injury, acupuncture and hyperthermia may improve microcirculation in local vessels supplying the tendon whose blood flow promotes repair and recovery of function.[8,9]

Note how the BL channel remains faithful to the small saphenous vein, as indicated by the cross-section in Figure 7-120. Too, notice the network of vascular anastomoses around the caudal ankle joint in Figure 7-119, revealing a rich supply of vessels and, as such, opportunities for autonomic neuromodulation that affects not only local tissues (e.g., calcaneal and other tendinous attachments) but also the body *in toto* by means of supraspinal reflexes.

Indications and Potential Point Combinations

- **Distal point for most pain problems, given its location at the caudal limit of the spinal cord segments supplying most of the body.**
- **Headache:** BL 60, ST 36, LI 4, GV 20.
- **Stiff neck:** BL 60, BL 10, GB 21, GV 20, appropriate trigger points.
- **Thoracic or lumbar pain:** BL 60, BL 23, BL 18, GV 14, GV 4.
- **Ankle or foot pain:** BL 60, isolate source of pain and its pattern and treat accordingly.
- **Sciatica:** BL 60, BL 23, BL 25, BL 40, GB 30, local trigger points.[10]

Figure 7-120. The cross section at BL 60 reveals the continued connection between the BL channel and the small saphenous vein as well as the anatomic relationships of BL 60 to the peroneal (fibularis) tendons and the calcaneal tendon. Needle angle and depth depends on anatomic goals and clinical condition treated. That is, one might angle the insertion toward the tendons for proprioceptive adjustment and tendonitis pain or perpendicularly into the connective tissue for channel-based influences.

- **Chronic low back pain:** BL 60, BL 23, BL 40, BL 54, GB 34, Huatuojiaji, local trigger points.[11]

Evidence-Based Applications

- **HIV-related peripheral neuropathy** improved with electroacupuncture on BL 60, ST 36, KI 1, and LR 3.[1]
- Acupuncture at BL 24, BL 25, BL 26, BL 40, BL 57, BL 60, Huatuojiaji at L4 and L5, Yaoyan, LI 4, and LI 11 provided long-term relief in patients with **chronic low back pain.**[2]
- Acupuncture at BL 23, BL 25, GB 30, BL 40, BL 60, and GB 34, plus BL 31, BL 32, and BL 54 (as needed) improved the orthopedic management of **chronic low back pain.**[3]
- Acupuncture at SI 3, SI 14, LR 3, BL 10, BL 60, GB 20, GB 34, TH 5, trapezius myofascial trigger point, and the auricular point "cervical spine" provided greater pain relief of **chronic neck pain** compared to massage, but not sham laser.[4]
- Acupuncture at ST 36 and BL 60 provided safe and effective analgesia for **extracorporeal shock wave lithotripsy.**[5]
- Treating BL 60, ST 36, LR 3, and GB 34 with transcutaneous electrical stimulation decreased ankle spasticity and improved muscle function in patients after **acute stroke.**[6]
- Non-invasive stimulation of BL 60, KI 3, LR 3, and LI 4 reduced **acute post-operative pain** in hospitalized children.[12]

BL 61

Pu Can “Subservient Visitor”

On the lateral foot, in a tender depression on the lateral aspect of the calcaneus, approximately 1.5 cun distal and caudal to the lateral malleolus. Directly distal to BL 60 on the proximal border of the calcaneus.

Fat Pad

- **Lateral inframalleolar fat pad:** This poorly understood structure consists of a classical unilocular fatty tissue pad distinct from the subcutaneous plane. It lies deep to BL 61 and receives a medial perforating vessel from the small (or short) saphenous vein.

Clinical Relevance: The sural nerve courses superficial to the fat pad. Injury or swelling involving the lateral inframalleolar fat pad may incite neuralgia affecting the lateral 5th toe and 4th interspace between the digits.[1] Conversely, the fat pad may cushion the local neurovascular entities and protect them from compression injury.

Nerves

- **Sural nerve (S1, S2):** Arises from the tibial and common fibular nerves (usually). Supplies the skin on the caudal and the lateral aspects of the leg, and on the lateral foot by means of its branch, the lateral dorsal cutaneous nerve. Lateral calcaneal branches supply sensation to the heel.
- **Tibial nerve (L4, L5, S1-S3):** Supplies all the muscles in the caudal compartment of the leg and the calcaneal tendon. Branches into the medial and lateral plantar nerves, the nerve for the abductor digiti minimi, the medial calcaneal branch, and a branch for the quadratus plantae muscle.[2]

Clinical Relevance: The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression. Heel pain accompanied by tingling, burning, or loss of sensation suggest neuropathic injury by compression, traction, or other causes.[3]

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[4]

BL 67

Figure 7-121A. In ancient times, a visitor of inferior rank would kneel in front of the host, touching the site demarcated by BL 61; hence the name “Subservient Visitor”.[6] That said, the true significance of BL 61 rests with its relationship with the sural nerve and branches. This image depicts the course of the BL channel and its partner, the sural nerve, from its emergence through fascia at BL 58 to the terminal sural branches at BL 67. Patients with entrapment neuropathy of this nerve report pain and sensory loss along the distal BL channel.[7]

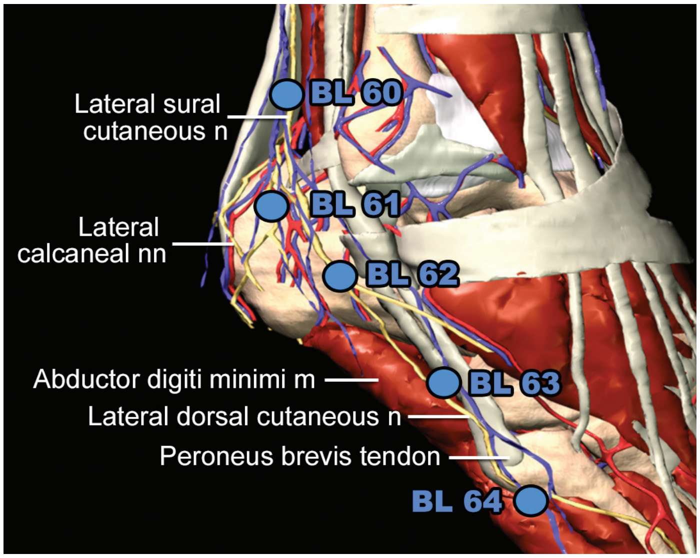

Figure 7-121B. This close-up examination of the nerves accessible to acupuncture at BL 61 reveals its value for calcaneal pain. A variety of mechanical stressors impact the calcaneus during the entire gait cycle.[8] Lateral heel pain from lateral calcaneal neuritis produces discomfort that radiates along the nerve as shown here; the pain may be difficult to localize in some cases. This contrasts with calcaneal stress fracture that leads to pain over the entire calcaneus or peroneal (fibularis) tendon disorders that cause pain on the lateral calcaneus and peroneal tubercle.

The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-121B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Vessels

- **Fibular (peroneal) artery, lateral branch:** Provides blood to the vicinity of the lateral malleolus.
- **Small saphenous vein:** Arises on the lateral side of the foot from the juncture of the dorsal venous arch with the dorsal vein of the little toe, ascends posterior to the lateral malleolus and along the lateral border of the calcaneal tendon. It ascends to the midline of the fibula and enters the deep fascia. It then ascends between the two heads of the gastrocnemius muscle and finally empties into the popliteal vein in the popliteal fossa.

Clinical Relevance: Neurovascular compression syndromes affect the lower limbs due to the anatomic configuration of vessels and nerves, as well as the orthostatic impact of the biped's upright position.[5] Vascular changes that lead to nerve compression include varicose veins, post-saphenectomy fibrotic adhesions, deep vein thrombosis, and previous phlebitis with subsequent fibrosis or scarring. Aneurysms, pseudoaneurysms, and hemangiomata can also compress nerves. Although neurovascular compression syndromes appear less commonly in the lateral ankle and foot than elsewhere on the distal limb, a patient who complains of pain, or expresses symptoms of hyperalgesia, allodynia, and paresthesias along the nerve course may be describing the sequelae of nerve entrapment due to vascular enlargement.

Indications and Potential Point Combinations

- **Swelling and pain in leg, knee, or heel:** BL 61, check for trigger points in the peroneus brevis and peroneus tertius muscles that refer to the heel.
- **Lateral heel pain:** BL 61, palpate for trigger points. Consider BL 59, BL 60, and BL 64.
- **Lateral dorsal cutaneous neuropathy:** BL 61, palpate for source of compression from BL 57 to BL 64, and needle, massage, or treat with laser therapy accordingly.

Figure 7-122. Although little myotendinous tissue exists at this level, nerves supplying the joint as well as BL 61 and BL 62 provide proprioceptive input for joint stability and strength. Note the lateral calcaneal vessel in this image and the fatty tissue it accompanies. The lateral inframalleolar fat pad will be found in this locale.

BL 62

Shen Mai "Extending Vessel"

On the lateral side of the foot, in a depression distal to the lateral malleolus, just caudal to the peroneus (fibularis) longus and brevis tendons.

Alternate location: At the dorsal-plantar skin junction (where the skin color changes); this point is called BL 62'.

Bony Protuberance

- **Calcaneal peroneal tubercle:** An extremely variable, inconsistently present (in about 50% of feet) bony prominence constituting an embryonic remnant.[3]

Clinical Relevance: The size of the calcaneal peroneal tubercle varies in size from a small nodule less than 1 mm high to a prominent spur measuring 1 cm in elevation. Calcaneal peroneal tubercle hypertrophy can cause stenosing tenosynovitis of the peroneal tendons. Note the relationship of the tubercle to BL 62 in Figure 7-123.

Nerves

- **Sural nerve (S1, S2):** Arises from the tibial and common fibular nerves (usually). Supplies sensation to the skin on the caudal and the lateral aspects of the leg, and on the lateral foot by means of its branch, the lateral dorsal cutaneous nerve. Lateral calcaneal branches supply sensation to the heel.

Clinical Relevance: The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression. Heel pain accompanied by tingling, burning, or loss of sensation suggest neuropathic injury by compression, traction, or other causes.[4]

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[5] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-121B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Lateral heel pain from lateral calcaneal neuritis produces discomfort that radiates along the nerve as shown here; the pain may be difficult to localize in some cases. This contrasts with calcaneal stress fracture that leads to pain over the entire calcaneus or peroneal (fibularis) tendon disorders that cause pain on the lateral calcaneus and peroneal tubercle.

The yoga position "downward dog" may stretch the lateral sural cutaneous nerve and produce neuropathic pain or dysesthesia.[6]

Vessels

- **Anterior lateral malleolar artery and vein:** Supply and drain the lateral ankle rgion.

Figure 7-123. BL 62, the "Extending Vessel" point sits at the juncture of intersecting neurovascular structures situated over the lateral dorsal cutaneous nerve and accompanying vessels. BL 62 and its coupled point, SI 3, also supposedly connect with the Governor Vessel, or Du Mai, consisting of the azygous network of veins and perispinal plexuses.

Clinical Relevance: Fractures of the proximal 5th metatarsal bone are some of the most common fractures that affect the foot; mechanisms involve falling from standing height or ankle twist with fixed forefoot.[7] Repetitive, cyclic loading can induce stress fractures of the 5th metatarsal. Inadequate circulation to this lateral portion of the foot contributes to incomplete or delayed fracture healing. Medical acupuncture, massage, and laser therapy support restoration of blood flow, resolution of pain, and bone healing.

Indications and Potential Point Combinations

- **Sore feet, supposedly "fallen arches" that may actually reflect the pain of active trigger points in muscles of the foot:** BL 62, trigger points in muscles identified as dysfunctional. Trigger points in the abductor digiti minimi radiate pain to the bottom of the foot in the distal 5th metatarsal region. For foot pain on the medial aspect, palpate for trigger points in the abductor hallucis muscle.

Flexor digitorum brevis muscle trigger points produce pain on the plantar surface of the foot. Check for trigger points in the calf as well, including the tibialis posterior, which may radiate pain to the plantar aspect of the foot.

- **Swelling and pain in leg, knee, or heel:** BL 62, BL 61, check for trigger points in the peroneus brevis and peroneus tertius muscles that refer to the heel.
- **Lateral heel pain:** BL 62, BL 61, palpate for trigger points. Consider BL 59, BL 60, and BL 64.
- **Lateral dorsal cutaneous neuropathy:** BL 62, palpate for source of compression from BL 57 to BL 64, and needle, massage, or treat with laser therapy accordingly.
- **Headaches:** BL 62, SI 3, GV 20, isolate trigger points and neuropathic nerves responsible for radiating pain to the head. Address trigeminal or vagal input to the dura if necessary.
- **Vertigo:** BL 62, SI 3, BL 10, GB 20, GV 20.
- **Back pain, especially in the lumbar region:** BL 62, BL 60, BL 40, BL 23, BL 25, BL 54, GB 30.
- **Cerebrovascular disease, spinal cord injury:** BL 62, SI 3, GV points at the level of injury.

Evidence-Based Applications

- Electroacupuncture applied to SI 3, BL 62, and four locations on the ear relating to the spinal cord contributed significantly to neurologic and functional recoveries in patients with spinal cord injuries.[1]
- Acupuncture at BL 23, BL 25, BL 26, BL 36, BL 40, BL 62, GB 31, and GB 34 for patients with lumbar disc protrusion resulted in significant pain reduction.[2]
- Consecutive stimulation of BL 62 activates the contralateral cerebellum and ipsilateral inferior parietal hemisphere.[8]

BL 63

Jin Men "Golden Gate"

On the lateral foot, in the depression proximal to the tuberosity of the 5th metatarsal bone, plantar to the calcaneocuboid joint, at the dorsal/plantar skin junction where the skin color changes.

Tendons and Muscles

- **Peroneus (Fibularis) longus and brevis tendons:** Evert the ankle, stabilize its subtalar motion. Maximally contract with side-to-side movement and jumping. Provide proprioceptive information regarding joint position.
- **Abductor digiti minimi muscle:** Abducts and flexes the 5th digit.

Clinical Relevance: Peroneal tendon injuries occur commonly but are frequently misdiagnosed as lateral ankle sprains. The tendinopathy can become chronic and dramatically compromise foot function. In that both tendons course through the territory described by BL 63, this point becomes significant in treating lateral ankle and foot pain arising subsequent to ankle inversion injuries. Faulty biomechanics of the core and pelvic limb predispose patients to chronic atraumatic peroneal tendinopathy. Ankle instability can produce chronic tendon pathology. Peroneal tendon subluxation causes snapping along the lateral ankle, possibly accompanied by ankle weakening and pain.

Nerves

- **Superficial peroneal (fibular) nerve (L5, S1, S2):** Innervates the peroneal (fibularis) longus and brevis muscles, and provides sensation to the skin on the distal third of the anterior surface of the leg and dorsum of the foot.
- **Lateral plantar nerve (S2, S3):** Innervates the abductor digiti minimi muscle, the quadratus plantae, and the flexor digiti minimi brevis mm; a deep branch supplies the plantar and dorsal interossei muscle, the lateral three lumbrical muscles, and the adductor hallucis muscle. It also supplies the skin on the sole of the lateral one and a half digits. The inferior calcaneal nerve, the first branch of the lateral plantar nerve, supplies the abductor digiti minimi muscle at its proximal attachment to the lateral tarsus.
- **Sural nerve (S1, S2):** Arises from the tibial and common fibular nerves (usually). Supplies sensation to the skin on the caudal and the lateral aspects of the leg, and on the lateral foot by means of its branch, the lateral dorsal cutaneous nerve. Lateral calcaneal branches supply sensation to the heel.

Clinical Relevance: The fascial sheath surrounding the caudal calf muscles will at times entrap the sural nerve as it emerges near BL 58. At the ankle, branches of the sural nerve can also experience compression.

From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[1] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-124A) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

The yoga position "downward dog" may stretch the lateral sural cutaneous nerve and produce neuropathic pain or dysesthesia.[2]

Figure 7-125. The anatomic proximity of BL 63 to the calcaneocuboid joint illustrates its value for calcaneocuboid pain (cuboid syndrome). Note that the location for BL 63 may land either atop the two tendons, providing for neuromodulation of the Golgi tendon organs they contain, or over the joint to influence arthrokinematics and joint labra (fibroadipose synovial folds) that could contribute to cuboid syndrome.

indistinguishable from plantar fasciitis. Another term for nerve entrapment of the inferior calcaneal nerve is "Baxter's neuropathy".[3] The cause of this neuropathy involves altered biomechanics due to a number of problems, including calcaneal tendinosis or posterior tibial tendon dysfunction.[4] Other causes include fallen arch, plantar calcaneal enthesophytes, and plantar fasciitis itself. Patients exhibit atrophy of the abductor digiti minimi muscle after chronic compression of the inferior calcaneal nerve. Conservative treatment measures for Baxter's neuropathy include acupuncture and laser therapy, as well as manual therapies to address plantar fascial restrictions and contributions from calcaneal tendinopathy.

Vessels

- **Anterior lateral malleolar artery and vein:** Supply and drain the lateral ankle region.

Clinical Relevance: Fractures of the proximal 5th metatarsal bone are some of the most common fractures that affect the foot; mechanisms involve falling from standing height or ankle twist with fixed forefoot. Repetitive, cyclic loading can induce stress fractures of the 5th metatarsal. Inadequate circulation to this lateral portion of the foot contributes to incomplete or delayed fracture healing. Medical acupuncture, massage, and laser therapy support restoration of blood flow, resolution of pain, and bone healing.

Indications and Potential Point Combinations

- **Lateral ankle or foot pain:** BL 63, BL 62, BL 60, BL 65.
- **Ankle instability:** BL 63, BL 62, KI 3, KI 6, relevant trigger points.
- **Atrophy of the abductor digiti minimi muscle:** BL 63, BL 60, BL 65, KI 6, KI 2, KI 3, and relevant trigger points.
- **Cuboid syndrome (calcaneocuboid joint dysfunction, causing lateral midfoot pain):** BL 63, BL 62, manual therapy may be of value unless contraindicated .

BL 64

Jing Gu "Capital Bone"

On the lateral foot, in a depression distal to the tuberosity of the 5th metatarsal bone, at the dorsal/plantar skin junction. The tuberosity of the 5th metatarsal bone is the most prominent bony prominence on the lateral mid-foot.

Muscles

- **Abductor digiti minimi muscle:** Abducts and flexes the 5th digit.
- **Flexor digiti minimi brevis muscle:** Flexes the proximal phalanx of the 5th digit, thereby assisting with flexion.

Clinical Relevance: Pain stemming from myofascial dysfunction in either the abductor digiti minimi or flexor digiti minimi brevis muscles may produce pain while ambulating as well as paresthesias and edema of the foot. Causes include wearing shoes that are too small for the foot, traumatic injury to the foot or toes, or wearing a cast or boot that disturbs proper foot biomechanics.

Nerves

- **Lateral dorsal cutaneous nerve of the foot (termination of the sural nerve, which usually arises from both the tibial and peroneal nerves – S1):** Provides sensation to the lateral portion of the foot.
- **Lateral plantar nerve (from tibial nerve – S1, S2):** Supplies the following muscles – quadratus plantae, abductor digiti minimi, flexor digiti minimi brevis, plantar and dorsal interosseous, lateral three lumbricals, and adductor hallucis. Supplies the skin of the sole, lateral to the midline of the 4th digit.

Clinical Relevance: From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[2] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-126) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Vessels

- Anterior lateral malleolar artery and vein: Supply and drain the lateral ankle region.

Clinical Relevance: Fractures of the proximal 5th metatarsal bone are some of the most common fractures that affect the foot; mechanisms involve falling from standing height or ankle twist with fixed forefoot.[3] Repetitive, cyclic loading can induce stress fractures of the 5th metatarsal. Inadequate circulation to this lateral portion of the foot contributes to incomplete or delayed fracture healing. Medical acupuncture, massage, and laser therapy support restoration of blood flow, resolution of pain, and bone healing.

BL 64
Tuberosity of the 5th metatarsal
Abductor digiti minimi m
Dorsal digital a

Figure 7-126. BL 64, the "Capital Bone" point, resides in the depression distal to the tuberosity of the 5th metatarsal, known as the "capital" bone in ancient China.[4] Note that indications for BL 64 are beginning to include non-foot problems related to sympathetic overactivation. The relatively higher proportion of sympathetic innervation to distal acupuncture points produces a greater impact on systemic autonomic neurmodulation than that afforded by more proximal sites of stimulation.

Indications and Potential Point Combinations

- **Headache, neck stiffness, low back pain, knee pain:** BL 64, BL 60, KI 10, BL 10, plus focal points for the pain itself and sources of radiation.
- **Hypertension:** BL 64, ST 36, LR 3, GV 20.
- **Tachycardia:** BL 64, ST 36, HT 3, HT 7.
- **Seizures:** BL 64, LR 3, KI 7, BL 10, GV 20, PC 6.
- **Lateral midfoot pain:** Palpate for trigger points in the abductor digiti minimi and flexor digiti minimi brevis muscles. Needle accordingly. Consider BL 64.

Evidence-Based Application

- Low frequency EA to BL 64 and BL 65 induced neuronal nitric oxide synthase (nNOS) in the gracile nucleus; enhanced neuronal nitric oxide synthase in this region may mediate **somatosympathetic reflexes.**[1]

BL 65

Shu Gu "Restraining Bone" or "Bundle Bone"

On the lateral foot, in a depression proximal and plantar to the 5th metatarsophalangeal (MTP) joint, at the dorsal/plantar skin border. Locate by running the finger in a distal direction along the lateral aspect of the foot, starting from BL 64, until the finger falls into a nook proximal to the MTP joint.

Muscles

- **Abductor digiti minimi muscle:** Abducts and flexes the 5th digit.
- **Flexor digiti minimi brevis muscle:** Flexes the proximal phalanx of the 5th digit, thereby assisting with flexion.

Clinical Relevance: Pain stemming from myofascial dysfunction in either the abductor digiti minimi or flexor digiti minimi brevis muscles may produce pain while ambulating as well as paresthesias and edema of the foot. Causes include wearing shoes that are too small for the foot, traumatic injury to the foot or toes, or wearing a cast or boot that disturbs proper foot biomechanics.

Nerves

- **Lateral dorsal cutaneous nerve of the foot (termination of the sural nerve, which usually arises from both the tibial and peroneal nerves – S1):** Provides sensation to the lateral portion of the foot.
- **Lateral plantar nerve (from tibial nerve – S1, S2):** Supplies the following muscles – quadratus plantae, abductor digiti minimi, flexor digiti minimi brevis, plantar and dorsal interosseous, lateral three lumbricals, and adductor hallucis. Supplies the skin of the sole, lateral to the midline of the 4th digit.

Clinical Relevance: The lateral plantar nerve is the main nerve stimulated when walking.[2] From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[3] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-128B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Subcalcaneal pain may arise due to compression of the nerves to either the abductor digiti minimi or flexor digiti minimi brevis, branches of the lateral plantar nerve. Causes of compression include calcaneal spurs, fascial features of the foot, or myofascial restriction from other intrinsic muscles of the foot such as the quadratus plantae.[4]

Soft tissue restriction and stiffening, as occurs with diabetes mellitus and gout, negatively impacts the spatial distribution of stress.[5] A stiff foot receives less tissue nourishment and elimination of metabolic waste as a result of circulatory compromise. Injuries in the pathologic foot may begin in the deep tissues of the foot and affect, as a consequence, more superficial structures such as the plantar aponeurosis. This argues for the incorporation of acupuncture, massage, and laser therapy in systemic conditions that secondarily impact soft tissue flexibility, as it may encourage ambulation and exercise that improves overall health.

Vessels

- **Plantar metatarsal artery, from the plantar arterial arch:** Supply skin, fascia, and muscles in the foot.

Clinical Relevance: Surgery of the forefoot risks damaging the metatarsal heads by traumatizing blood supply.[6] Too, disease states such as diabetes mellitus that increase stiffness in the soft tissues of the feet show blood flow reduction due to myofascial restriction of about 28%.[7] Acupuncture and related techniques may help support recovery of microcirculation.

Indications and Potential Point Combinations

- **Headache, dizziness, stiff neck:** BL 65, BL 10.
- **Low back pain:** BL 65, BL 23, GV 4.
- **Sciatica:** BL 65, BL 36, BL 40, BL 60, KI 3.
- **Foot pain in the 5th metatarsophalangeal region:** BL 65.

Check for trigger points in the BL 63 and BL 64 regions from the abductor digiti minimi and flexor digiti minimi brevis muscles.

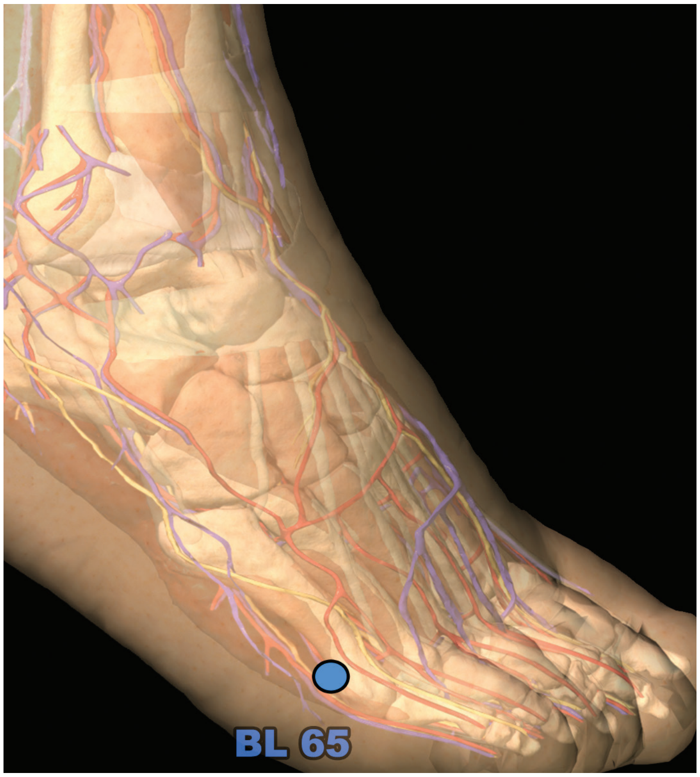

Figure 7-127. "Restraining bone" for BL 65 refers to the head of the 5th metatarsal bone where the hands reach out to when tying shoes.[8] "Bundle Bone" describes the pressure imparted onto the 5th MTP joint when wearing tight shoes.

Evidence-Based Applications

- Low frequency EA to BL 64 and BL 65 induced neuronal nitric oxide synthase (nNOS) in the gracile nucleus; enhanced nNOS in this region may mediate **somatosympathetic reflexes.**[1]

BL 66

Tong Gu "Foot Connecting Valley" or "Valley Passage"

On the foot, in a depression distal and inferior to the 5th metatarsophalangeal joint, at the dorsal/plantar skin border. Find BL 65 first, then run the finger over the joint, into a depression at the base of the fifth toe.

Muscles

- **Abductor digiti minimi muscle:** Abducts and flexes the 5th digit.
- **Flexor digiti minimi brevis muscle:** Flexes the proximal phalanx of the 5th digit, thereby assisting with flexion. Distal to the 5th MTP, only a few fibers insert onto the lateral aspect of the base of the proximal phalanx of the little toe. These fibers have been assumed to be a separate muscle and called "opponens digiti quinti" by some anatomists, or "opponens digiti minimi" by others.

Clinical Relevance: Pain stemming from myofascial dysfunction in either the abductor digiti minimi or flexor digiti minimi brevis muscles may produce pain while ambulating as well as paresthesias and edema of the foot. Causes include wearing shoes that are too small for the foot, traumatic injury to the foot or toes, or wearing a cast or boot that disturbs proper foot biomechanics.

Nerves

- **Lateral dorsal cutaneous nerve of the foot (termination of the sural nerve, which usually arises from both the tibial and peroneal nerves – S1):** Provides sensation to the lateral portion of the foot.
- **Lateral plantar nerve (from tibial nerve – S1, S2):** Supplies the following muscles – quadratus plantae, abductor digiti minimi, flexor digiti minimi brevis, plantar and dorsal interosseous, lateral three lumbricals, and adductor hallucis. Supplies the skin of the sole, lateral to the midline of the 4th digit.

Clinical Relevance: The lateral plantar nerve is the main nerve stimulated when walking.[2] From a functional perspective, mechanoreceptors located along the lateral foot and supplied by the sural nerve branches assist in maintaining upright stance and control over posture.[3] The body accomplishes this by means of reflexes connecting cutaneous receptors of the foot (supplied by the lateral dorsal cutaneous nerve, shown in Figure 7-128B) with the erector spinae muscles of the lower back. Acupuncture and related techniques that activate nerve endings along the BL channel of the foot thus aid in balance and support of an upright posture and dynamic stabilization during gait and ground contact.

Subcalcaneal pain may arise due to compression of the nerves to either the abductor digiti minimi or flexor digiti minimi brevis, branches of the lateral plantar nerve. Causes of compression include calcaneal spurs, fascial features of the foot, or myofascial restriction from other intrinsic muscles of the foot such as the quadratus plantae.[4]

Soft tissue restriction and stiffening, as occurs with diabetes mellitus and gout, negatively impacts the spatial distribution of stress.[5] A stiff foot receives less tissue nourishment and elimination of metabolic waste as a result of circulatory compromise. Injuries in the pathologic foot may begin in the deep tissues of the foot and affect, as a consequence, more superficial structures such as the plantar aponeurosis. This argues for the incorporation of acupuncture, massage, and laser therapy in systemic conditions that secondarily impact soft tissue flexibility, as it may encourage ambulation and exercise that improves overall health.

Vessels

- **Dorsal and plantar digital arteries and accompanying veins:** Respectively supply and drain blood from the digits from and to their arches.

Clinical Relevance: Surgery of the forefoot risks damaging the

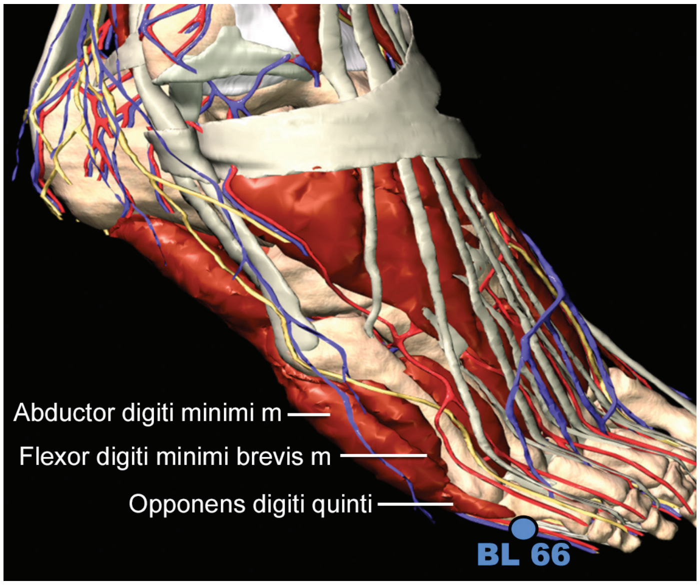

Figure 7-128A. Note the distal attachment of the opponens digiti quinti muscle at BL 66; often considered a component of the flexor digiti minimi brevis muscle. Its myotendinous attachment houses Golgi tendon organs that support proper foot mechanics and weight distribution.

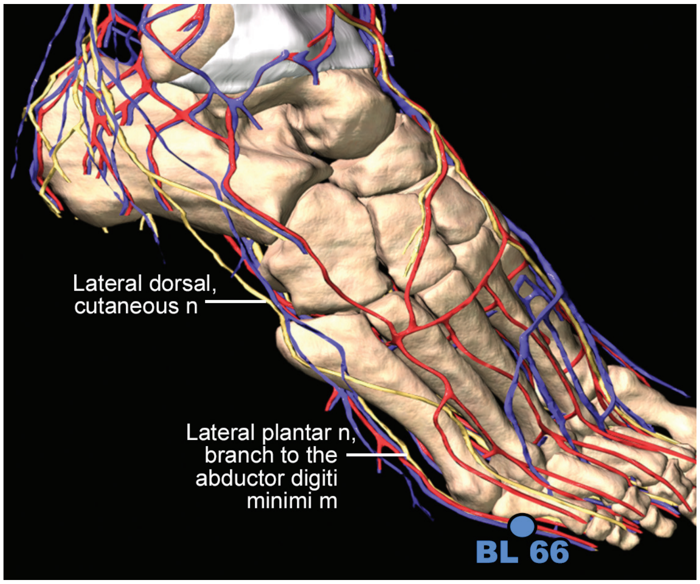

Lateral dorsal, cutaneous n
Lateral plantar n, branch to the abductor digiti minimi m
BL 66

Figure 7-128B. The name "Valley Passage" for BL 66 refers to the bony valley distal to the 5th metatarsophalangeal joint, that, by dint of its location on the lateral foot, speaks to two groups of nerves and vessels, on the dorsal and plantar aspects, as indicated here.

metatarsal heads by traumatizing blood supply.[6] Disease states such as diabetes mellitus that stiffen the soft tissues of the feet show blood flow reduction of about 28%.[7] Acupuncture and related techniques may help support recovery of microcirculation.

The distal acupuncture points on the hands and feet acquire extra importance in acupuncture due to the robust sympathetic innervation supplying vessels in these areas. The ting (most distal points) on each channel except for KI land in vessel beds packed with microvasculature as arteries transition to veins. Flow in these microvessels is dynamic; signals received by afferents in these vessels transmit information to higher centers that govern autonomic balance. As such, the clinical effects of distal points typically include hemodynamic conditions such as neck pain and vascular headache, especially for BL points, considering its trajectory to the head and neck. These influences contrast with those conferred by distal points on the ST line that treat sinusitis and dental pain, in keeping with the course of its channel over the sinuses and face. The neuroanatomic substrates for the channels' trajectories reside in the spinal cord, cranial nerves, and brain. They integrate and refine sensorimotor and autonomic control over movement and response; the acupuncture channels serve to highlight and connect the components of these neural representations of the network controlling somatic structures.

Indications and Potential Point Combinations

- **Neck stiffness, headache:** BL 66, BL 10, GB 21, SI 3.
- **Lateral foot pain:** BL 66, check for trigger points in the abductor digiti minimi muscle.

Evidence-Based Application

- Acupuncture stimulation of HT 8, BL 66, and LR 2 effectively reduced elevated body temperature induced by **bacterial inflammation,** in part by suppressing hypothalamic production of pro-inflammatory cytokines.[1]

BL 67
Zhi Yin "Reaching Yin"

Lateral to the base of the nail of the little toe, in line with the lateral border of the nail. Otherwise known as located at the "width of a Chinese leek leaf from the corner of the nail".

Nerves

- **Lateral dorsal cutaneous nerve of the foot (termination of the sural nerve, which usually arises from both the tibial and peroneal nerves – S1):** Provides sensation to the lateral portion of the foot.
- **Dorsal digital branches of proper plantar digital nerve:** Arise from the common plantar digital nerve; supply the plantar portion of the little toe and part of the dorsal surface of the distal phalanx.

Clinical Relevance: Involved in autonomic neuromodulation, recovery of sensation to toes damaged by trauma or iatrogenic maneuvers. Connections to the lumbosacral spinal cord segments provide opportunities for neuromodulation of pelvic organ function, as shown in the ability of BL 67 to correct breech presentation through affects on the uterus and its contents.

Vessels

- **Dorsal digital branches of proper plantar digital artery and anastomosis with terminal branches of dorsal digital artery, all for the 5th toe:** Supply the dorsum of the distal phalanx and the nail bed.
- **Dorsal digital veins:** Assist in venous drainage from the foot. Terminate in the dorsal venous arch.

Clinical Relevance: Produce local and systemic autonomic neuromodulation and hemodynamic regulation through nervi vasorum supplying small vessels and connect to higher centers governing hemodynamic homeostasis.

Indications and Potential Point Combinations

- **Headache:** BL 67, BL 10, GV 20.
- **Pain or weakness in the pelvic limbs:** BL 67, ST 36, BL 40, BL 54.
- **Eye pain:** BL 67, GB 1, TH 23.
- **Heat in the soles of the feet:** BL 67, LR 3, SP 3.
- **Nasal congestion:** BL 67, LI 20, GV 24.5 (Yintang).
- **Malposition of the fetus:** Moxibustion at BL 67.
- **Placental retention:** BL 67.

Evidence-Based Applications

- Needling of BL 67 and CV 3 effectively treated **retained placenta** in a case series.[1]
- Needling GB 34, ST 36, SP 6, and BL 67 may help decrease the need for **labor induction and cesarean section.**[2]
- Acupressure at LI 4 and BL 67 significantly decreased **labor pain** during the active phase of the first stage of labor.[3]
- Acupuncture plus moxibustion, or moxibustion alone, at BL 67 safely helps reposition the fetus in cases of **breech presentation.**[4,5, 10,11]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[6]
- Acupuncture at BL 67 **activated the occipital lobe of the brain, or visual cortex.**[7] Likewise, acupuncture stimulation of BL 67 in rats caused an increase in the number of c-fos-positive cells in the primary visual cortex of binocularly deprived rats, in contrast to stimulation of BL 54, which had little effect.[8]
- Laser acupuncture at BL 67 activates the **cuneus** (corresponding to Brodmann Area 18) and the **medial occipital gyrus** (Brodmann Area 19) of the **ipsilateral visual cortex.**[9]
- Laser acupuncture at BL 67 **increased blood flow velocity in the posterior cerebral artery** with minimal changes in the anterior cerebral artery.[12]

Channel 8:: The Kidney (KI)

After the BL channel (below, in blue, on the left-hand image) ends on the lateral aspect of the little toe, the Kidney (KI) channel (below, in purple, on the right-hand image) picks up the trajectory on the bottom of the foot. As it travels north, the KI line encircles the medial malleolus, courses over the medial pelvic limb, and arrives at the pubis just off midline. It remains paramedian as it ascends the abdomen and thorax until it ends at the sternoclavicular junction.

KI 1

This side-by-side comparison illustrates the similarity of the ways in which both the BL (in blue, on the left) and KI (in purple, on the right) channels reside adjacent to the midline pathways, GV and CV, respectively.

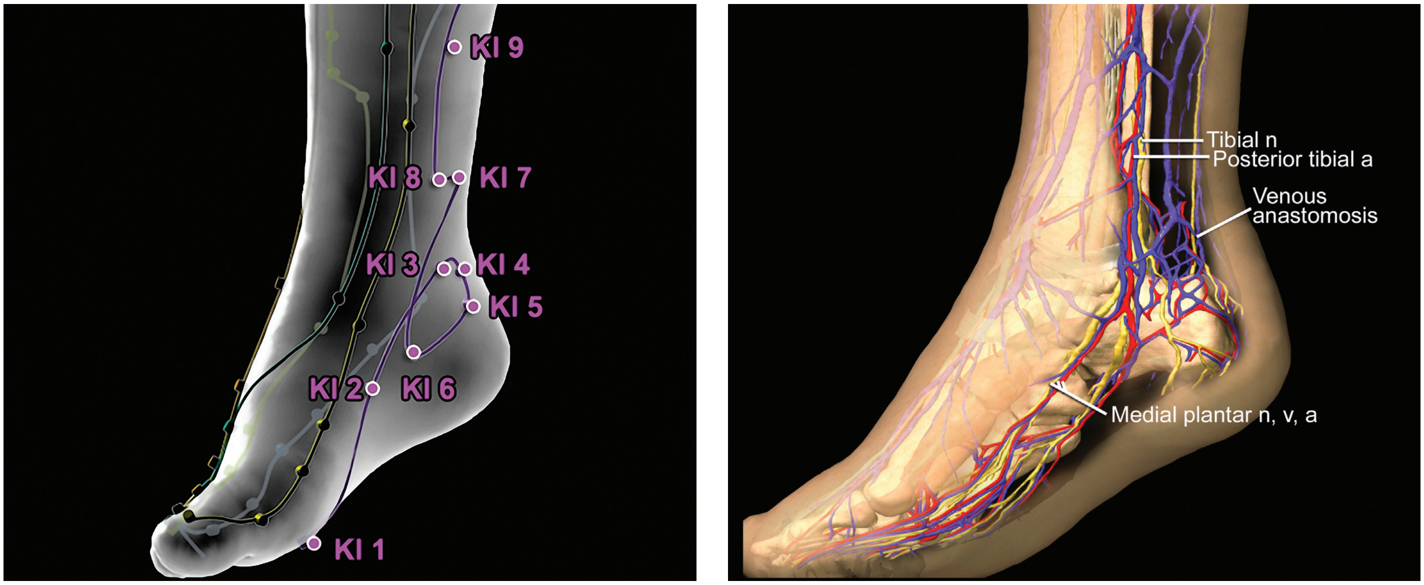
Neural Basis of the KI Channel

The fourteen channels form seven pairs: LU-LI, ST-SP, HT-SI, BL-KI, PC-TH, GB-LR, and GV-CV. Each pair exhibits anatomical complementarity, whether neural, vascular, bony, and/or myofascial. Chinese Medicine considers these Yin-Yang pairs, with Yin channels travel over more fleshy territory vulnerable to injury. Yang surfaces exhibit more dense muscularity.

KI and BL enjoy similar parallels, as noted by comparing the two channels' trajectories in the full-length images above. Both course close to the midline over sites of spinal nerve branching. KI points on the trunk denote locations where *ventral rami* branch. Conversely, BL points correspond to loci of *dorsal* rami divisions. On the pelvic limb, KI and BL points partner with "Yin" and "Yang" divisions of the sciatic nerve, respectively. That is, KI hugs the medial (Yin) surface and tibial nerve while BL accompanies the fibular nerve more faithfully on the lateral (Yang) leg and foot.

Vascular Basis of the KI Channel

The vascular basis of the KI channel comprises the medial plantar, posterior tibial, inferior epigastric, and internal thoracic vessels, illustrated in the following images.



This comparison illustrates how the medial plantar and posterior tibial vessels follow the KI trajectory, even recapitulating the circle near the medial malleolus with a venous anastomosis.

From the groin to the sternoclavicular junction, the vascular basis of the KI channel corresponds to the collateral vessel network on the thoracoabdominal wall, where inferior epigastric join internal thoracic vessels. These connections provide alternate routes for blood to bypass blockages. In the case of aortoiliac occlusion, for example, arterial blood to the pelvic limb would encourage the opening of access to these collateral channels.

KI 1

Yong Quan"Gushing Spring"

On the plantar foot, between the 2nd and 3rd metatarsal bones, in a depression that forms behind the ball of the foot when the foot is plantarflexed. Approximately 1/3 the distance from the base of the 2nd toe to the heel.[1]

An alternative location for KI 1, at the medial nail angle of the little toe, obviates the need to needle the bottom of the foot. However, structures affected differ markedly, as illustrated by Figure 8-2.

NOTE: Use judiciously; painful to needle. Consider laser therapy or myofascial work as an alternative method of stimulation.

Connective Tissues

- **Plantar aponeurosis:** The central portion of the plantar fascia that forms a thick and strong plantar aponeurosis. These longitudinally arranged bands of dense connective tissue exhibit a thick central portion, flanked on each side by weaker zones. The plantar fascia maintains the structure of the foot by supporting the longitudinal arch; its strength helps protect the plantar surface from injury.

Clinical Relevance: A number of pathologies affect the plantar aponeurosis; many lead to changes in the texture, thickness, and health of the structure.[6] When it dysfunctions, the mechanical properties of the aponeurosis become affected and, as such, changes take place in its normal deformation properties during walking and running, the interaction between the foot and footwear, and the ability of neural receptors in the aponeurosis to signal information about pressure.[7] This unique fascial structure stores part of the strain energy imparted during ambulation; it returns a portion to the foot in a quasi-elastic recoil effect that assists in maintaining the longitudinal arch of the medial foot. As such, surgical release of the plantar aponeurosis leads to arch height decrease and foot elongation.

While actual cases of plantar fasciitis result from excessive and repeated loading focused on the plantar aponeurosis,[8] the phrase "plantar fasciitis" has become a catchall diagnosis for pain affecting the sole of the foot. Not all cases of plantar pain involve the plantar aponeurosis, plantar fascia, or inflammation. In actuality, as described below in the "Muscles" section below, a number of trigger points refer pain to the plantar region. They respond remarkably well to acupuncture, massage, and laser therapy. Even in cases of actual inflammation of the plantar fascia, nonsurgical therapy should precede fasciotomy or fasciectomy, in the hope of avoiding either maneuver.[9]

Muscles and Tendons

- **Flexor digitorum brevis muscle (for the 2nd and 3rd digits):** Flexes the lateral four pedal digits (toes).

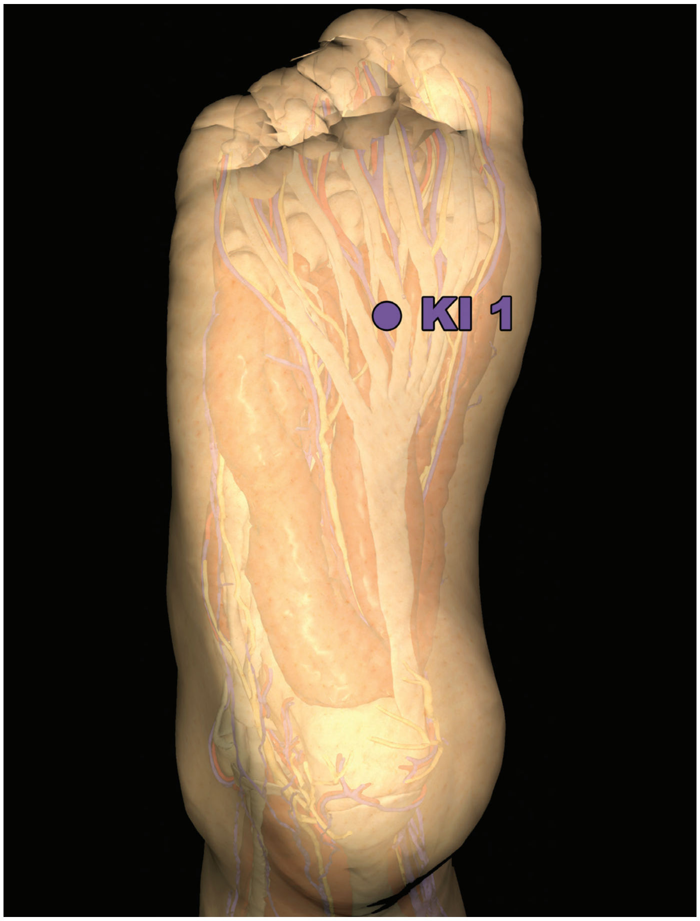

Figure 8-1. One finds KI 1, "Gushing Spring", in the well of the sole, just behind the ball of the foot.

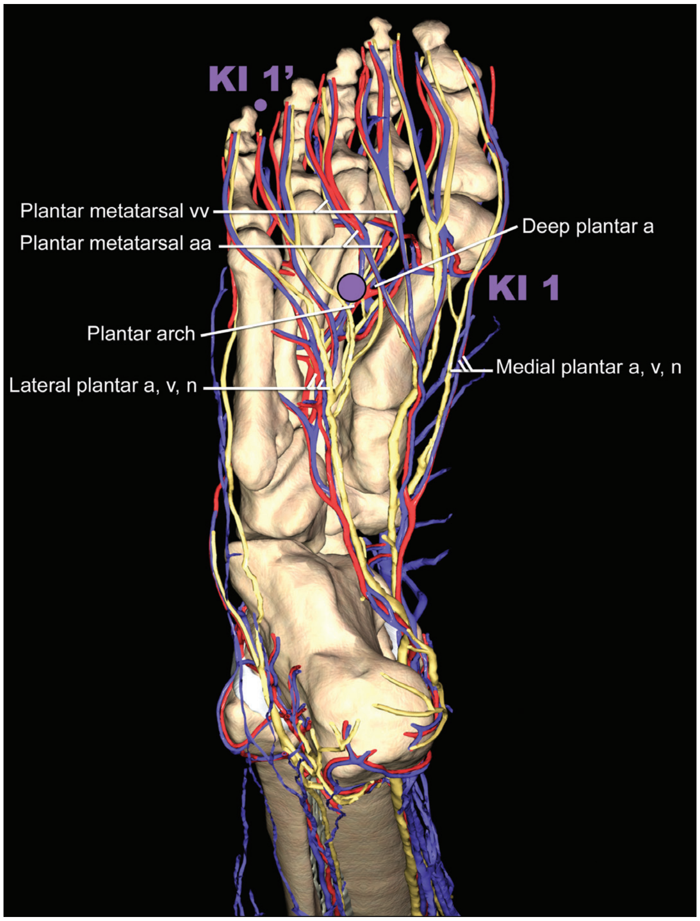

Figure 8-2. The fluid pushing through "Gushing Spring" pulsates through the deep plantar artery, shown here. This image also depicts the location of KI 1', which would one would find on the dorsum of the little toe. "KI 1'" is the alternate location for KI 1.

- **Flexor hallucis longus tendon:** Flexes both joints of the great toe, assists in plantarflexion of the ankle.
- **Flexor hallucis brevis muscle:** Flexes the hallux, or great toe.
- **1st and 2nd lumbrical muscles:** Flex the proximal phalanges and extends the middle and distal phalanges.
- **Adductor hallucis muscle, transverse head:** Adducts the great toe.
- **1st plantar interosseous muscle:** Adducts the digits and flexes the metatarsophalangeal joints.

Clinical Relevance: Muscles that refer pain to the KI 1 region include the adductor hallucis, flexor digitorum brevis, flexor digitorum longus, tibialis posterior, soleus, 1st dorsal interosseous, and even the gastrocnemius muscle. View Figure 8-4 to analyze which muscles and from which direction and depth muscles of the foot are accessible for trigger point activation by treating KI 1.

Patients bedridden for months display disuse atrophy in many muscles of the pelvic limb, but after bed rest ends, the flexor hallucis longus, flexor digitorum longus, and lateral gastrocnemius require longer than three months to recover.[10] As such, when treating patients who have been bedridden for months, return to ambulation may cause stress on weakened structures, thus more susceptible to myofascial dysfunction.

Nerves

- **Medial plantar nerve (larger terminal branch of tibial nerve):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle.
- **Lateral plantar nerve (smaller terminal branch of tibial nerve):** The lateral plantar nerve supplies the skin on the lateral sole, lateral to a line bisecting the fourth digit. It also supplies the following muscles: quadratus plantae, abductor digiti minimi, flexor digiti minimi brevis, plantar and dorsal interossei, lateral three lumbricals, and adductor hallucis.
- **The common plantar digital nerve between 2nd and 3rd toes:** Supplies the skin of the plantar surface of the toes. The dorsal surfaces of the distal tips of the toes (as in the nail bed regions) receive branches from the proper plantar digital nerves.

Clinical Relevance: Tibial nerve compression in the tarsal tunnel causes neuropathy that, in diabetic patients, can increase risk of pedal ulceration, pain, and sensory loss.[11] This may affect nerves coursing to KI 1.

Branches of the tibial nerve, including the medial plantar nerve, can become compressed by compartment syndrome in the foot. Crush injury of the foot commonly increases pressure in the foot compartments. Compression of the structures coursing through the calcaneal compartment predisposes patients to claw toes secondary to contracture of the quadratus plantae muscle.[12] Entrapment of the medial plantar nerve as it courses through the calcaneal tunnel may follow, perhaps leading to hallux varus as a complication.

The nervi vasorum of the vessels supplying KI 1 activate the autonomic neuromodulatory effects that influence local and systemic hemodynamic balance. Deep, sustained stimulation of KI 1 may invoke the "Lazarus" phenomenon of reviving individuals after cardiopulmonary arrest (when conventional measures have failed) through activation of sympathetic nerve pathways.[13]

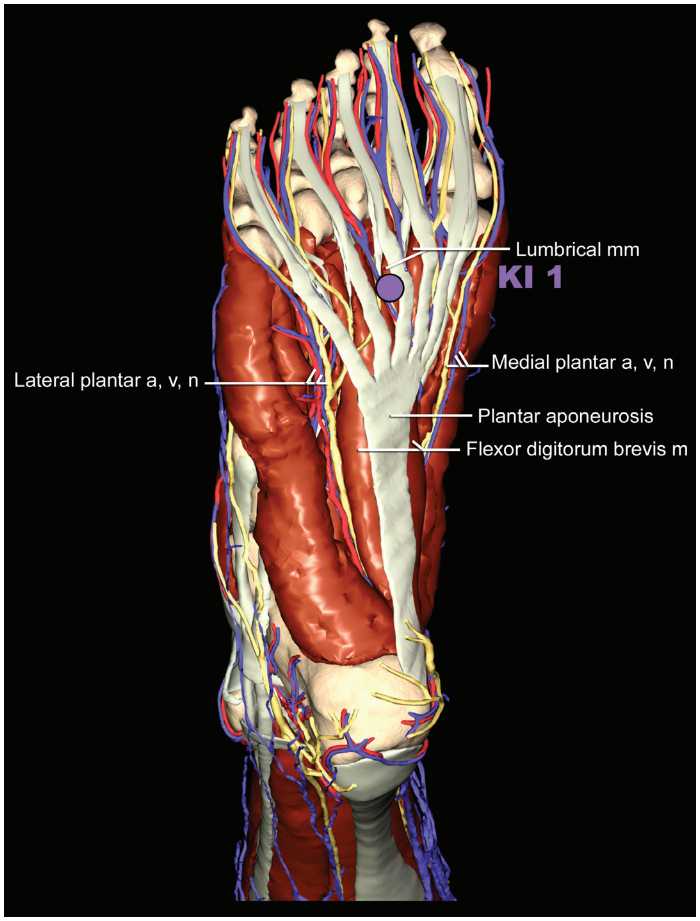

Figure 8-3. Painful disorders of the plantar aponeurosis include plantar fasciitis, calcaneal enthesophytes, rheumatoid nodules, infection, and plantar fibromatosis. However, trigger points in the deep intrinsic muscles of the foot can cause local pain mimicking other problems. In addition, referred pain from trigger points from the flexor digitorum longus, soleus, and tibialis posterior muscles may also produce significant plantar pain. Careful myofascial palpation that identifies trigger points in the adductor hallucis and flexor hallucis brevis muscles (intrinsic foot muscles) as well as more proximal sights assists in defining the source of pain. Patients may then avoid surgery through proper diagnosis and treatment with trigger point deactivation.

Vessels

- **Plantar metatarsal artery and plantar arterial arch:** The plantar arterial arch provides four plantar metatarsal arteries and three perforating arteries. These vessels supply numerous branches to the skin, fascia, and muscles of the foot. They adjoin the superficial branches of the lateral and medial plantar arteries to supply the digits through plantar digital arteries.
- **Plantar metatarsal veins and plantar venous arch:** Join the great saphenous vein.
- **Lateral plantar artery:** Unites the medial plantar artery and deep plantar artery to form the plantar arch.

Clinical Relevance: Diabetes mellitus appears to decrease the density of perivascular nerve fibers and the reactivity of vascular

Figure 8-4. While one would not ordinarily needle KI 1 without strong cause, trigger points in the adductor hallucis and flexor hallucis brevis could produce foot pain in this region. Alternatives to needling include massage, acupressure, and laser therapy. Due to the profound sensitivity of the sole of the foot, deep needling may not be possible, although some patients tolerate this successfully. This cross-section depicts the depth and angle required to reach various trigger points in the foot with needling, laser, or manual means.

muscles in plantar metatarsal arteries.[14] This raises consideration of neuromodulation through acupuncture, laser therapy, and massage to exogenously improve circulation through similarly compromised vessels.

Reflux in foot veins is associated with venous toe and forefoot ulceration.[15] Although ulceration typically affects the dorsum of the toes and forefoot, pressure changes secondary to plantar compression and triceps surae contraction contribute to venous drainage of the foot and ankle. Neuromodulation and circulatory modulation by means of acupuncture, massage, and laser therapy should improve venous drainage and tissue maintenance.

Indications and Potential Point Combinations

- Typically reserved for extreme circumstances due to the discomfort of needling KI 1. Applications include **needle shock (i.e., vasovagal syncope after acupuncture), seizures, coma, and stroke.**
- **Plantar foot pain:** Palpate for myofascial trigger points in the adductor hallucis and flexor hallucis brevis muscles. Apply acupressure at KI1and the myofascial trigger points if found.
- **Pelvic limb paralysis:** KI 1, Bafeng, ST 36, affected nerves and spinal cord segments.
- **Memory impairment due to vascular dementia:** KI 1, LU 11, PC 9, and HT 9;[16] laser stimulation of KI 1.[17]
- Infant nasal obstruction: Pressure at KI 1.[18]

Evidence-Based Applications

- **HIV-related peripheral neuropathy** improved with electroacupuncture on BL 60, ST 36, KI 1, and LR 3.[2]
- Acupressure to KI 1, GB 34, ST 36, and SP 6 helped relieve fatigue in patients with **end-stage renal disease.**[3]
- A case series reports effectiveness of strong needling of KI 1 arousal from **coma.**[4]
- Acupressure at KI 1, HT 7, and auricular Shenmen improved both quality of sleep and quality of life among patients with **end-stage renal disease who suffered from sleep disturbance.**[5]
- **Cardiopulmonary resuscitation, unsuccessfully achieved by other means:** Place the thumbs of both hands on the patient's KI 1 of one foot with other fingers on the dorsum of the foot, also applying pressure. Apply for at least 5 minutes. As claimed by the author of a letter discussing this "Lazarus phenomenon" of producing "unexpected recovery of native circulation in apparently dead patients", thirty inpatients recovered even after other methods failed.[19] If strong thumb pressure is not an option, one can use the tip of a retracted or covered pain, the eraser end of a pencil, or the handle tip of a toothbrush.

KI 2

Ran Gu "Blazing Valley"

On the medial aspect of the foot, in a depression distal and inferior to the tuberosity of the navicular bone, at the dorsal/plantar skin junction.

Muscles

- **Abductor hallucis muscle:** Abducts the great toe.

Clinical Relevance: Tension and trigger point pathology of the medial foot frequently results in medial foot pain involving the abductor hallucis muscle. Trigger points in the abductor hallucis that land the vicinity of KI 2 refer pain strongly to the caudal calcaneus and along the medial foot at SP 3.

Whereas myofascial dysfunction of the abductor hallucis muscle responds quickly and dramatically to physical medicine maneuvers, compartment syndrome can constitute a surgical emergency. Compartment syndrome of the medial foot affecting the abductor hallucis muscle and neurovascular contents can follow surgery, fracture, crush injury, vascular insult, or even minor or unrecognized injury, especially in children.[1] Patients with compartment syndrome complain of the "7 P's", namely: pain, paresthesias, pulselessness, paralysis, pressure, pain with passive stretch, and induration with palpation.[2] Pain, out of proportion with the stimulus, may be the most sensitive clinical symptom.

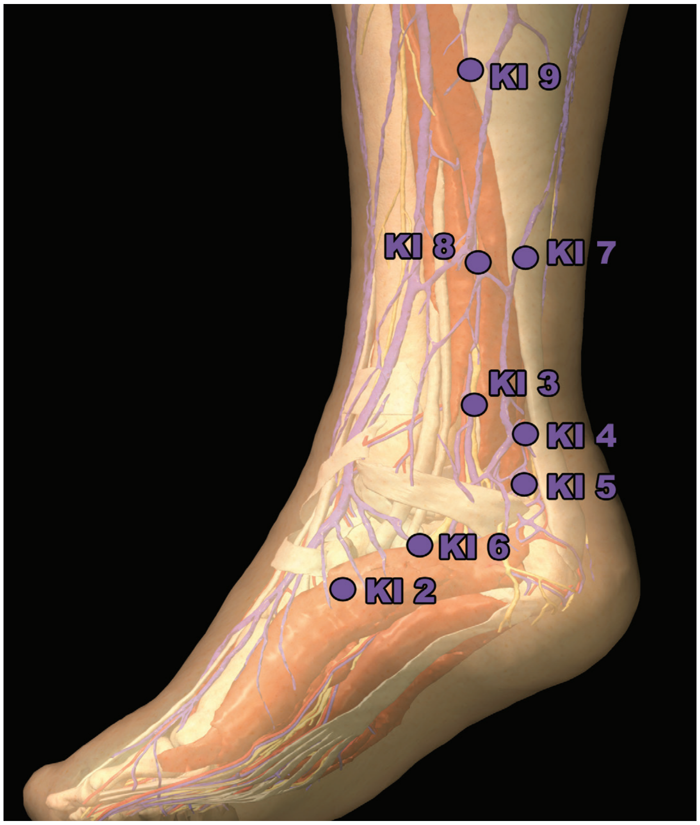

Figure 8-5. The abductor hallucis muscle, seen through semi-transparent skin in this image beneath KI 2, belongs to the group of superficial intrinsic muscles of the foot dubbed "sore foot muscles" by Travell and Simons. The pain pattern generated by myofascial trigger points in the area of KI 2 and KI 6 refer strongly to the heel, in the KI 3, KI 4, and KI 5 zone.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Medial plantar nerve (larger terminal branch of tibial nerve):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle. Figure 8-6 depicts and compares the courses of the medial and lateral plantar nerves and vessels. The tibial nerve branches into the medial and lateral plantar nerves that each travel through individual tunnels separated by a septum. The site of bifurcation of the tibial nerve into the plantar couple identifies a source of compression at the ankle. Inside the tunnel through which the medial plantar nerve courses, the abductor hallucis muscle forms the roof. Tension and contracture of the abductor hallucis muscle can compress the nerve, causing numbness, tingling, cramping, and burning pain on the plantar foot at the metatarsal heads and possibly the heel.[3] Symptoms of tarsal tunnel syndrome, which this condition is called, worsen with weight bearing and pressure applied to the tunnel. They improve with both rest and elevation of the foot. On neurologic examination, sensory examination may reveal reduction in two-point discrimination and vibratory perception of the great toe. Some patients report a history of surgical release for plantar fasciitis with insufficient relief; these individuals may have been experiencing plantar nerve compression misdiagnosed as plantar fasciitis. While surgical release of the tarsal tunnel serves as one option, many patients would prefer likely conservative approaches to reduce myofascial restriction.

Clinical Relevance: Tibial nerve compression in the tarsal tunnel causes neuropathy that, in diabetic patients, can increase risk of pedal ulceration, pain, and sensory loss.[4] This may affect nerves coursing through KI 2.

Branches of the tibial nerve, including the medial plantar nerve, can also experience compression during compartment syndrome in the foot. Crush injury of the foot commonly increases pressure in the foot compartments. Compression of the structures coursing through the calcaneal compartment predisposes patients to claw toes secondary to contracture of the quadratus plantae muscle.[5] Entrapment of the medial plantar nerve as it courses through the calcaneal tunnel may follow, perhaps leading to hallux varus as a complication.

Vessels

- **Medial plantar artery:** This small artery mainly supplies the muscles of the great toe, but most of the plantar digital arteries arise from the medial plantar artery. Its superficial branch provides circulation to the skin on the medial aspect of the sole.

This branch gives off digital branches which accompany the medial plantar nerve's digital nerve branches.

- **Medial marginal vein of the foot:** Joins the great saphenous vein, receiving blood from the superficial veins of the sole which form the plantar venous network.

Clinical Relevance: Diabetes mellitus decreases the density of perivascular nerve fibers and the reactivity of vascular muscles

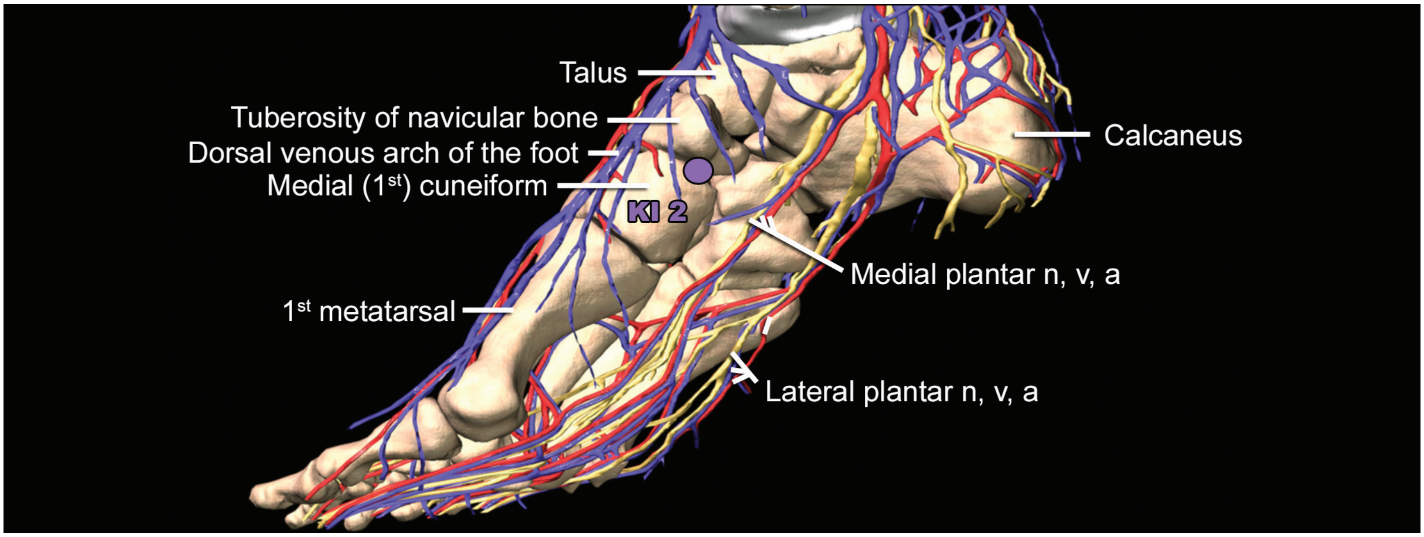

Figure 8-6. While the "blazing" in "Blazing Valley" may refer to the foot pain experienced when an examiner presses a trigger point at KI 2, "valley" indicates the the depression distal and plantar to the tuberosity of the navicular bone.

in plantar metatarsal arteries.[6] This raises consideration of neuromodulation through acupuncture, laser therapy, and massage to exogenously improve circulation through similarly compromised vessels.

Reflux in foot veins is associated with venous toe and forefoot ulceration.[7] Although ulceration typically affects the dorsum of the toes and forefoot, pressure changes secondary to forces affecting the arch as well as contraction of the triceps surae muscles (i.e., gastrocnemius and soleus muscles) contribute to venous drainage of the foot and ankle. Neuromodulation and circulatory balance provided by acupuncture, massage, and laser therapy should improve venous drainage and tissue maintenance.

Compartment syndrome of the medial foot may result in increased venous and capillary pressures due to venous outflow obstruction.[8] Arterial blood has difficulty entering the fixed space, causing ischemia that compromises the integrity of capillary walls. As permeability of the walls increase, edema, hypoxia, and acidosis take hold. Complications such as nerve and muscle dysfunction ensue after three hours of ischemia. Damage to nerves may become irreversible after 12-24 hours, about the time that muscle contracture begins. While awaiting or considering urgent fasciotomy, treatment with laser therapy may aid tissue health. However, given the urgency required for surgical treatment, practitioner should not delay proper diagnosis or treatment of compartment syndrome in order to wait and see if physical medicine treatments help over the course of several days.

Pseudoaneurysm of the medial plantar artery may follow trauma, iatrogenic vascular intervention, or intravenous drug administration.[9] Although pseudoaneurysm of the lateral plantar artery more commonly occurs, it can afflict the medial vessel in cases of ankle sprain, penetrating injury, iatrogenic causes such as arthroscopy and fracture fixation, and contusion. Patients exhibit pain, swelling, and hematoma from the trauma, the pseudoaneurysm, or both. Left untreated, pseudoaneurysms may either resolve spontaneously or grow gradually and compress the local neurovascular structures. When a pseudoaneurysm falls in the vicinity of KI 2, tibial nerve compression and tarsal tunnel syndrome may result. Whether surgical or nonsurgical means are employed to address the vascular damage, acupuncture, laser, and massage can improve nerve function and circulation, allowing the patient to recover more fully.

Indications and Potential Point Combinations

- **Reproductive problems:** Pain, irregular menses, uterine prolapse, vulvar pruritus: KI 2, LR 5, CV 2.
- **Urinary disorders, including cystitis:** KI 2, SP 6, CV 3, BL 28, BL 32.
- **Foot pain, medial aspect:** Palpate for trigger points, select KI 2 plus local points for dysfunctional abductor hallucis muscle.
- **Tarsal tunnel syndrome:** KI 3, KI 5, KI 6, KI 2, SP 6, local trigger points. Laser therapy, massage to entire ankle to free surrounding fascia.

KI 3

Tai Xi "Supreme Stream", "Great Torrent", or "Great Ravine"

On the medial ankle region, midway between the most prominent aspect of the medial malleolus and the caudal border of the Achilles tendon, immediately caudal to the pulsation of the posterior tibial artery. Lands between the tendons of the flexor hallucis longus (caudal to KI 3) and the flexor digitorum longus (cranial to KI 3), shown in Figure 8-8.

Muscles and Tendons

- **Flexor digitorum longus tendon:** Flexes the lateral four pedal digits. Supports the longitudinal pedal arch and plantarflexes the ankle.
- **Flexor hallucis longus muscle and tendon:** Flexes all joints of the great toe.

Supports medial longitudinal pedal arches. Weakly plantarflexes the ankle. The flexor hallucis longus tendon passes through a sheath created by the flexor retinaculum at the caudal talus and a fibro-osseous tunnel formed along the medial calcaneus and distal sustentaculum tali. The tendon changes direction at a number of sites, including the caudal talar tubercles, sustentaculum tali, the Master Knot of Henry, and the 1st metatarsophalangeal-sesamoid joint complex. These anatomic pulley sites can coincide with areas of tendon injury and pathology.[14] Cysts, exostoses, muscle hypertrophy, the presence of accessory muscles, and more further impact the tendon and predispose it to problems. Also, the flexor hallucis longus tendon is vulnerable to traumatic injury along its entire route.[15]

- **Plantaris tendon:** Assists the gastrocnemius muscle in knee flexion and ankle plantarflexion.
- **Posterior tibialis tendon:** The posterior tibialis inverts the foot and provides ankle plantarflexion.

Clinical Relevance: Trigger point pathology in the flexor digitorum muscle at about the level of BL 56 travels down the tendon, coursing through KI 3 and KI 7, expanding to the sole of the foot. Trigger points in the calf at about BL 56 and BL 57, refer pain strongly to BL 57 and even more strongly to the calcaneal tendon before reaching the sole of the foot. Sustained trigger point dysfunction and myofascial restriction shorten myofibrils and place added tension on tendons, impacting biomechanics and subjecting loci crossing bony prominences to extra wear and tear.

Repetitive tendon injuries that become chronic state lead to pain and disability. Chronic tendon disorders fall into two general categories: stenosing tenosynovitis and tendinosis.[16] Stenosing tenosynovitis manifests as adhesions that interfere with tendon glide. Tendinosis, on the other hand, involves degeneration of the connective tissue exhibited as tears with nodule production, tendon thickening, mucoid degeneration, and/or lengthening of the tendon. Tendon lengthening contributes to hypermobile joints and other biomechanical dysfunction. Stenosing tenosynovitis frequently affects the flexor hallucis longus tendon of ballet dancers due to the en pointe position they employ, placing large

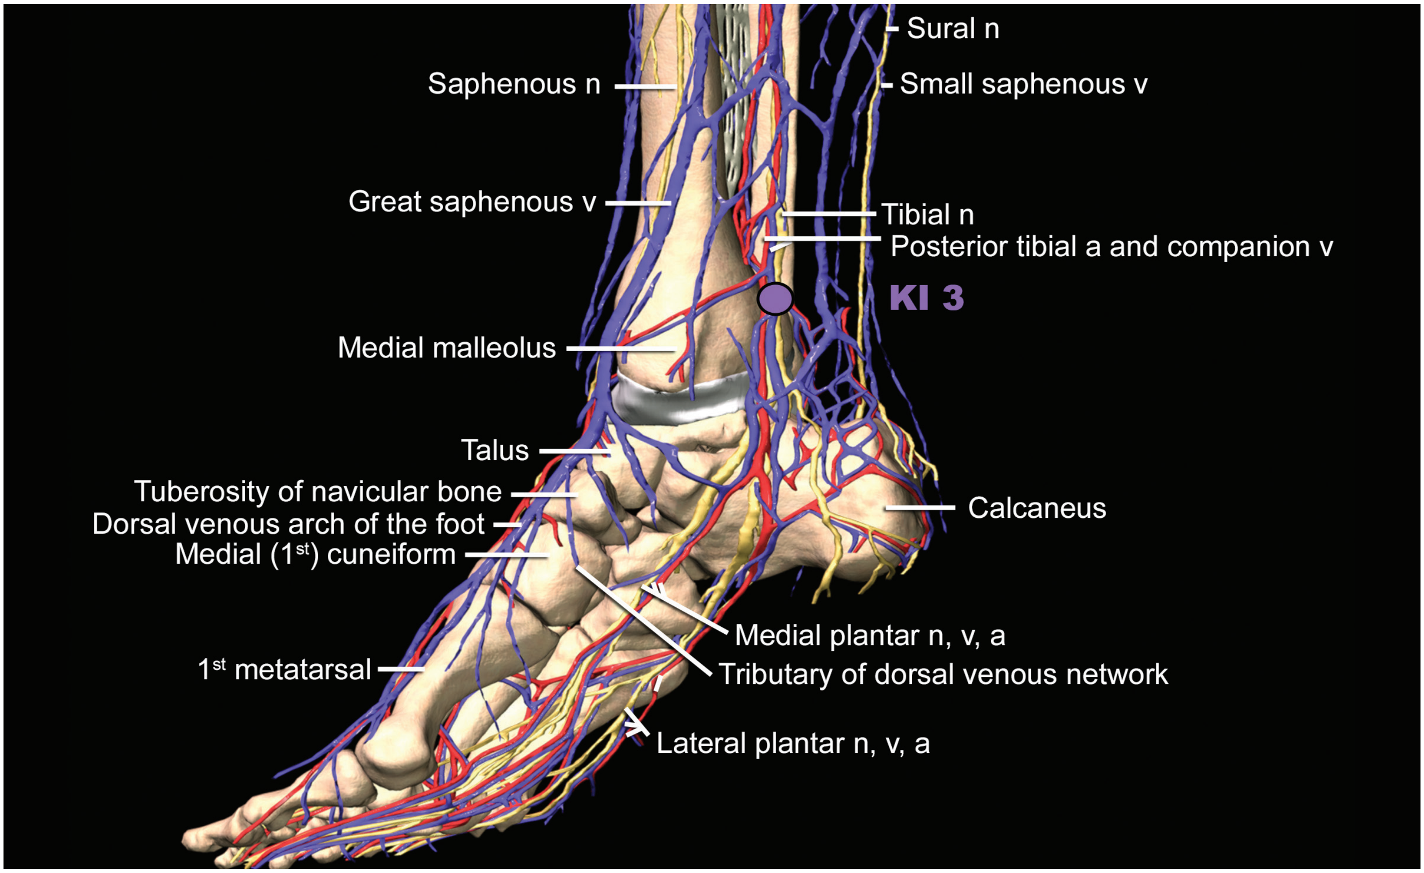

Figure 8-7A. The "Gushing Spring" (KI 1) where the KI line began becomes a "Great Torrent" at KI 3. The deeper structures shown here illustrate the neurovascular continuity between the bottom of the foot where KI 1 resides and KI 3.

supraphysiologic loads on the tendon; hence, the term "dancer's tendonitis". However, patients involved in equestrian activities, long distance running, sports requiring jumping, and tennis have also exhibited this condition. Running on the forefoot predisposes patients to developing tendonitis.[17] Tendinosis, in contrast, targets the tibialis posterior, calcaneal, and fibularis (peroneal) tendons.

The diagnosis of flexor hallucis longus stenosing tenosynovitis can be challenging, as patients simultaneously exhibit signs of not only tendon pathology, but also plantar fasciitis and tarsal tunnel syndrome. Many patients with this problem have already undergone conservative and/or surgical protocols for one or more of these conditions by the time they present for acupuncture or surgery; they continue to complain of pain and disability because the correct diagnosis has remained elusive. Myofascial palpation of the calf, ankle, and foot should aid in revealing the sources of trigger point pathology and soft tissue abnormalities.

Patients with flexor hallucis longus stenosing tenosynovitis may initially experience pain and tenderness at the caudomedial malleolar region (near KI 3). They then report that the pain radiates toward and along the medial arch of the foot.

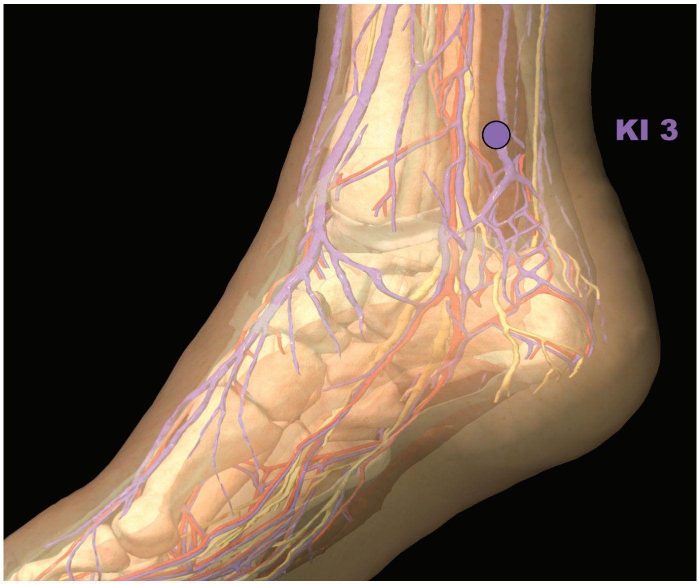

Figure 8-7B. The ravine containing the "raging torrent" of arterial blood flow beneath KI 3 consists of the groove formed between the tibia and the calcaneal tendon. One isolates KI 3 in the deep hole at the base of the ravine.

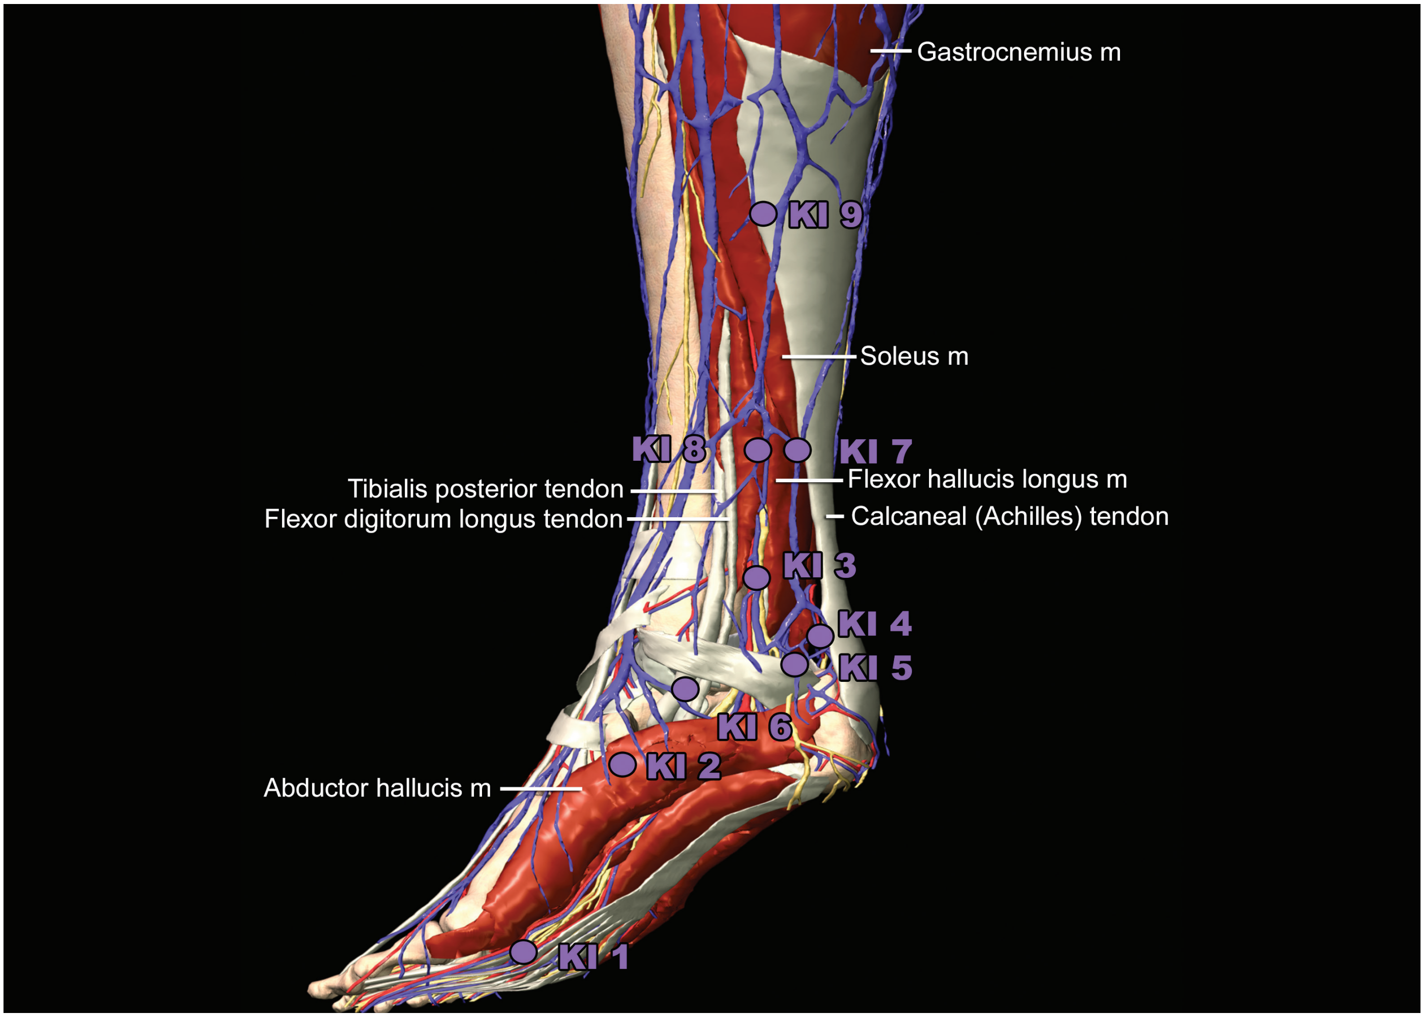

Figure 8-8. Two tendons, the flexor digitorum longus and flexor hallucis longus, create a groove that coddles KI 3 and its neural partner, the tibial nerve. Myofascial release of the tissue involving these two myotendinous structures from KI 3 to KI 7 and KI 8 will help relieve pressure on the nerve. Pain in the foot from tibial nerve compression at the ankle (a.k.a., tarsal tunnel syndrome) leads to pain that may be confused with plantar fasciitis. However, symptoms of plantar fasciitis improve with stretching and activity and worsen in the morning after first arising, whereas those associated with tarsal tunnel syndrome worsen with running and at the end of the day.[28]

Figure 8-9. In this image, KI 3 locates the tibial nerve caudal to the medial malleolus, opposite its counterpart, BL 60, on the lateral aspect of the ankle. Nestled in the nook with KI 3 reside the contents of the nearby tarsal tunnel, i.e., the tibial nerve, the posterior tibial vessels, and the posterior tibialis, flexor digitorum longus, and flexor hallucis longus tendons.

Shortening of the muscle restricts the movement of the hallux through its range of motion; crepitus or malfunction of the joint may occur. Bearing weight and performing athletic activity accentuate the pain. Triggering of the great toe, also called "hallux saltans", results when stenosing tenosynovitis afflicts the flexor hallucis longus at the fibro-osseous tunnel below the sustentaculum tali. As aforementioned, this condition occurs in dancers and athletes.

The tendinous contents of the tarsal tunnel, i.e., the tibialis posterior, flexor digitorum longus, and the flexor hallucis longus, may swell and compress the tibial nerve and posterior tibial vessels, shown in Figure 8-9. "Tarsal tunnel syndrome" involves tibial nerve compression at the ankle.[18] The tarsal tunnel extends from KI 3 to KI 6 or KI 2. It is located between the medial retinaculum of the ankle joint and the medial aspect of the calcaneus.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee. Distal to the medial malleolus and KI 3, the tibial nerve divides into the lateral and medial plantar nerves. Other nerve branches include the nerve for the abductor digiti minimi muscle and its branch to the quadratus plantae muscle, and the medial calcaneal nerve branch.[19] Any of these nerve branches may experience compression by connective tissue or vascular sources.

Clinical Relevance: In addition to the saphenous nerve, the sural and tibial nerves contribute cutaneous sensory branches to the medial ankle.[20] Branches from the saphenous nerve sometimes pierce the belly of the abductor hallucis muscle, leading to a connection with the medial plantar nerve by means of a small cutaneous branch. Iatrogenic injury to any of these nerves as in the case of tarsal tunnel release can lead to loss of sensation in the area of KI 3.

The tibial nerve and its distal branches may become entrapped at the medial ankle, producing a condition known as "tarsal tunnel syndrome" that leads to pain in the foot. It may cause neuropathic changes in tibial nerve branches coursing beneath KI 4 to KI 2. Compression of the tibial nerve most commonly takes place at the level of the tarsal tunnel, especially in athletes.[21] Inflammation and/or space-occupying lesions affecting structures comprising the tunnel readily impact the tibial nerve due to the inelastic nature of this fibro-osseous canal. Surgical incisions designed to decompress the tarsal tunnel extend roughly from KI 7 to KI 6; those patients who fail to respond to conservative treatment may require acupuncture, laser therapy, and/or massage to assist with healing not only the skin but also nerve function. Treatment would focus on "lining the scar" with needles inserted a small distance from the site of incision as well as releasing the connective tissue deep to the skin.

Treatment at KI 3 and nearby KI points helps release pressure on the nerve. Neuromodulation of structures at KI 3, proximal to the tunnel, influences the nerve prior to the compression.

Stimulation of KI 3 for neuromodulation of the tibial nerve influences micturition and defecation by reflexing through the sacral spinal cord segments that supply the pelvic floor, bladder, urinary sphincter, and anal sphincter.[22]

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.

Clinical Relevance: Primary venous aneurysms resulting from focal loss of normal connective tissue components in the venous wall potentially produce entrapment neuropathies. Such compressions typically occur in narrow anatomical sites comprising canals incorporating fibrous tissue from aponeuroses or septa.[23] The reversibility of symptoms associated with nerve compression corresponds to the chronicity and severity of the entrapment. Prolonged pressure on a nerve wall compromised its health by reducing blood flow through the vasa nervorum to the inner nerve fibers. The ischemia these fibers experience reduces nerve conduction velocity. The cross-section presented in Figure 8-9 reveals the proximity of the posterior tibial artery and venae concomitants to the tibial nerve, visually reinforcing the concept of how vascular enlargements may place pressure on nerves.

The posterior tibial vein covers the nerve for the abductor digiti minimi muscle. The posterior tibial artery and lateral plantar artery also cross the nerve to the abductor digiti minimi.[24] Vascular pressure on this nerve can produce pain and myofascial dysfunction in the abductor digiti minimi muscle.

Indications and Potential Point Combinations

- Like its lateral malleolar counterpart, BL 60, KI 3 provides a distal endnote option for many needling protocols, especially those benefiting by tibial nerve stimulation such as voiding dysfunction.
- **Urinary disorders (especially incontinence), voiding dysfunction:** Urinary frequency, enuresis, voiding dysfunction: K I3, SP 6, BL 32, BL 28, CV 3.
- **Reproductive problems:** Menstrual dysfunction, erectile dysfunction, sexual dysfunction, infertility: KI 3, PC 6, SP 4, BL 25, BL 23, GV 4.
- **Low back pain**: KI 3, BL 60, BL 23, trigger points in painful muscles, paraspinal (BL) points cranial and caudal to facilitated (sensitized) spinal cord segments.
- **Edema of the lower extremities:** KI 3, KI 16, SP 6, SP 9, CV 6.
- **Arthritic and degenerative diseases**: KI 3, BL 23, LI 4, ST 36, local painful points.
- **Tibial nerve injury following ankle arthroscopy through posteromedial portal:**[25] Acupuncture stimulation of KI 3, KI 7, KI 2; add laser therapy and massage for further recovery of surrounding soft tissue.

Evidence-Based Applications

- Case report of improvement with acupuncture at LR 3, KI 3, SP 6, and ST 36 for **sweating associated with malignancy,** unresponsive to other measures.[1]
- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of **enuresis.**[2]
- Acupuncture at ST 36, SP 6, SP 9, LR 3, KI 3, BL 23, and BL 28 improved symptoms of **recurrent cystitis in women.**[3]
- Acupuncture at CV 3, BL 23, BL 28, KI 3, SP 6, SP 9, LR 2 (or LR 3) provided effective prophylaxis of **recurrent lower urinary tract infection** in adult women.[4]
- Acupuncture at BL 23, BL 31, BL 32, BL 33, SP 6, KI 3, and LI 11 significantly improved **urge- and mixed-type incontinence** after acupuncture treatment among elderly women – a pilot study.[5]
- Acupuncture-based neuromodulation at KI 3, CV 3, CV 6, GV 4, BL 23, BL 32, LI 4, and ST 36 impacted recto-anal function and significantly improved **anal continence** in patients with fecal incontinence.[6]
- Electroacupuncture at CV 4, GV 20, SP 6, KI 3, and HT 7 may have afforded a modulating positive effect on psychogenic and non-psychogenic **erectile dysfunction.** It improved the quality of erection and restored sexual activity in 39% of patients.[7]
- Acupuncture at ST 30, ST 36, SP 4, SP 6, LR 3, KI 3, LI 4, and PC 6 plus moxibustion at BL 13, BL 22, BL 23, BL 52, CV 3, CV 4, CV 5, CV 6, CV 19, LU 9, and LR 14 significantly increased the percentage of normal sperm in patients with **idiopathic oligoasthenoteratozoospermia (OAT syndrome).**[8]
- Neuroanatomically, acupuncture at KI 3 may support **sexual performance** by sending signals to the sacral cord segments and inferior hypogastric plexus, via the tibial nerve.[9]
- Acupuncture at CV 4, BL 23, BL 32, LR 3, KI 3, ST 29, ST 36, SP 10, SP 6, and GV 20 resulted in improvement in **sperm quality,** specifically in the ultrastructural integrity of spermatozoa.[10]
- A case report indicated that acupuncture at ST 36, KI 3, and LR 3 produced dramatic improvement in **chronic venous ulceration.**[11]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[12]
- Acupuncture was shown to be an effective and safe adjunctive therapy for patients with **knee osteoarthritis,** using the following points: GB 34, GB 39, SP 6, SP 9, ST 35, ST 36, KI 3, and Xiyan.[13]
- Needling at KI 3, BL 60, LR 4, and LR 3 reduced **acute postoperative pain in hospitalized children.**[26]
- Electroacupuncture at HT 7, ST 36, ST 40, and KI 3 activated brain areas thought impaired by **Alzheimer's Disease.** [27]

KI 4

Da Zhong "Large Goblet", "Big Bell"

On the medial ankle region, inferior and posterior to KI 3, in a depression just anterior to the attachment site of the Achilles tendon onto the calcaneus, between the tendon and the bone.

Tendons

- **Calcaneal (Achilles) tendon:** Includes the tendons of the triceps surae muscle (i.e., the two-headed gastrocnemius and soleus muscles). This is also the strongest and thickest tendon in humans as well as the mostly commonly ruptured.[1] Figure 8-10 illustrates the way in which vessels supply the insertion, or osteotendinous junction. The middle third receives blood from the peroneal (fibular) artery while the proximal and distal attachments connect to the posterior tibial artery. Innervation arises from the sural and tibial nerves.

Clinical Relevance: The site of insertion of the calcaneal tendon at KI 4 and near BL 61 exhibits special characteristics that allow for the dissipation of stress from the tendon to the calcaneal bone.

Prolonged, low-intensity activity as well as highly vigorous activity can cause tendon injury, degeneration, and possibly rupture.[2] Calcaneal tendon ruptures heal slowly, requiring weeks to months due to the limited blood supply reaching the tendon. Acupuncture and related techniques, especially laser therapy, increase blood flow and accelerate repair. Laser therapy also reduces the stiffness and elongation that may follow tendon injury and repair. It benefits the process by promoting fibroblast proliferation, collagen synthesis, and circulation.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee. Posterior and inferior to the medial malleolus, the tibial nerve divides into the lateral and medial plantar nerves. Other nerve branches include the nerve for the abductor digiti minimi muscle and its branch to the quadratus plantae muscle, and the medial calcaneal nerve branch, which supplies the skin over the medial heel.[3] Any of these nerve branches may experience compression by connective tissue or vascular sources.

Clinical Relevance: The saphenous, sural and tibial nerves contribute cutaneous sensory branches to the medial ankle.[4] Branches from the saphenous nerve sometimes pierce the belly of the abductor hallucis muscle, leading to a connection with the medial plantar nerve by means of a small cutaneous branch. Iatrogenic injury to any of these nerves as in the case of tarsal tunnel release can lead to loss of sensation in the area of KI 4.

The tibial nerve and its distal branches may become entrapped at the medial ankle, producing a condition known as "tarsal tunnel syndrome" that leads to pain in the foot. It may cause neuropathic changes in tibial nerve branches coursing beneath KI 4 to KI 2. Compression of the tibial nerve most commonly takes place at the level of the tarsal tunnel, especially in athletes.[5] Inflammation and/or space-occupying lesions affecting structures comprising the tunnel readily impact the tibial nerve due to the inelastic nature of this fibro-osseous canal. Surgical

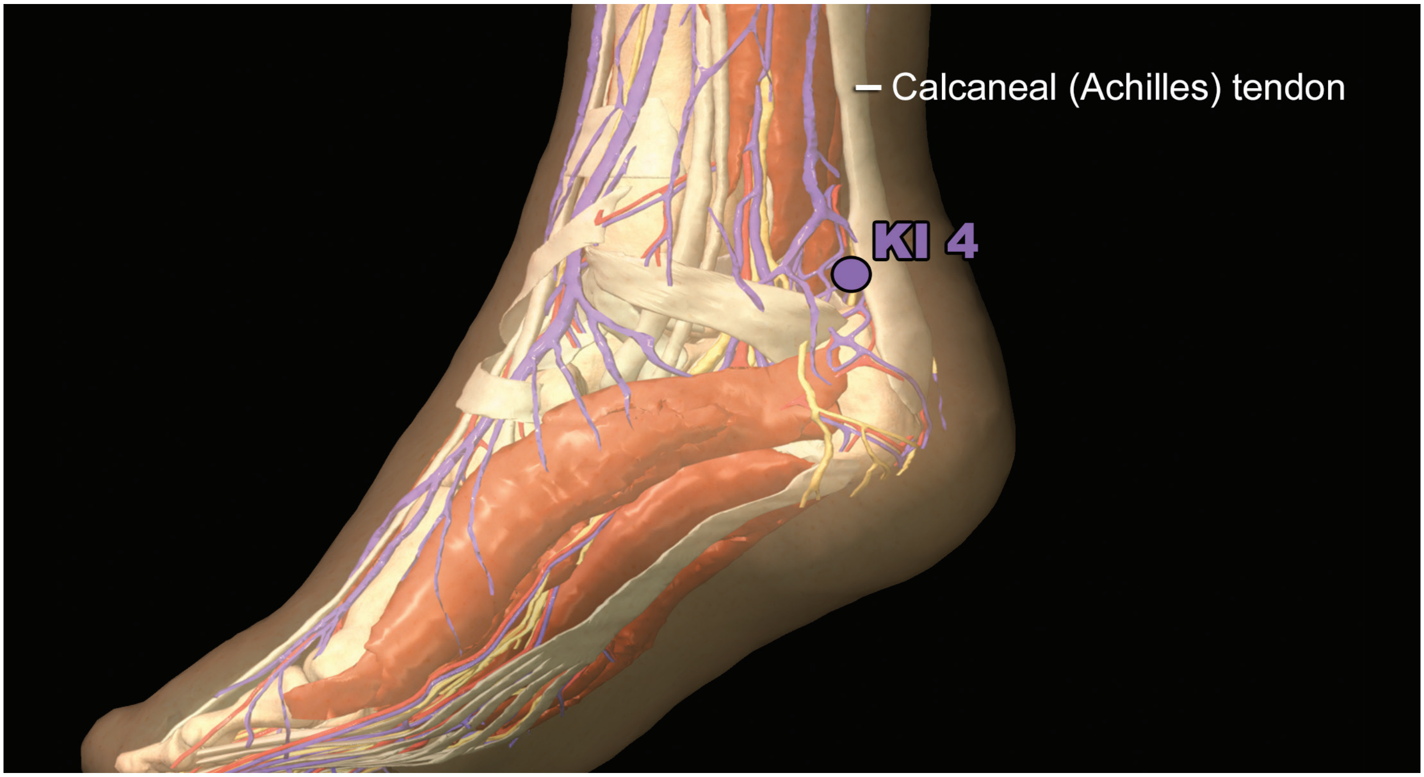

Figure 8-10. KI 4 identifies the site where the calcaneal tendon inserts onto the calcaneus. Pain at KI 4 and KI 5 may originate from a trigger point in the soleus muscle near KI 7; the pain extends to the plantar and lateral heel and KI 1. Note how the calcaneal tendon acquires a crescent shape as it inserts onto the calcaneus. This image also depicts the way in which the vessels and nerve fibers supply the calcaneal tendon at the osteotendinous junction.

Figure 8-11. The descriptive name for KI 4, i.e., "Large Goblet" or "Big Bell",,refers to the calcaneus, which widens and then tapers at the bottom. This cross-section exposes the close relationship of KI 4 to the calcaneal tendon and nearby vessels.

incisions designed to decompress the tarsal tunnel extend roughly from KI 7 to KI 6; those patients who fail to respond to conservative treatment may require acupuncture, laser therapy, and/or massage to assist with healing not only the skin but also nerve function. Treatment would focus on "lining the scar" with needles inserted a small distance from the site of incision as well as releasing the connective tissue deep to the skin.

Treatment at KI 4 and nearby KI points helps release pressure on the nerve. In addition to acupuncture, massage and laser therapy play important roles in alleviating pain, tension, and neuropathy of the ankle and foot.

Vessels

- **Medial calcaneal artery:** Arises from the posterior tibial artery to supply the medial calcaneal area.

Clinical Relevance: Acupuncture, laser therapy, and other physical medicine measures improve circulation to the calcaneal tendon by local and systemic means in the event of tendon injury.[6,7,8]

Indications and Potential Point Combinations

- **Heel pain:** KI 4; check for trigger points in the soleus ("jogger's heel") at KI 7, the tibialis posterior ("runner's nemesis") near BL 55, and the gastrocnemius ("calf cramp muscle") near LR 7.
- **Achilles tendinopathy:** KI 4, KI 3, BL 61, BL 60, plus trigger points in the muscular contributors to the calcaneal tendon: the gastrocnemius, the soleus, and the plantaris (BL 40). Add laser therapy and massage to support tissue health and repair.
- **Iatrogenic injury of the posterior neurovascular bundle during arthroscopy:** KI 3, KI 4, KI 6, BL 60, add laser therapy and massage to support recovery.

KI 5

Shui Quan "Water Spring"

On the medial side of the ankle, 1 cun below KI 3, in a depression proximal to the medial tubercle of the calcaneal tuberosity.

(Alternate location: in a depression midway between the tip of the medial malleolus and KI 4.)

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee. Posterior and inferior to the medial malleolus, the tibial nerve divides into the lateral and medial plantar nerves. Other nerve branches include the nerve for the abductor digiti minimi muscle and its branch to the quadratus plantae muscle, and the medial calcaneal nerve branch, which supplies the skin over the medial heel.[3] Any of these nerve branches may experience compression by connective tissue or vascular sources. A heel spur at KI 5 may entrap the nerve to the abductor digiti quinti (minimi) muscle.[4] Tension of the medial plantar fascia and deep fascia of the abductor hallucis muscle may also compress the nerve branch that supplies the quadratus plantae muscle.
- **Medial calcaneal nerve (from tibial nerve):** Supplies the skin over the medial calcaneal region.

Clinical Relevance: The saphenous, sural and tibial nerves contribute cutaneous sensory branches to the medial ankle.[5] Branches from the saphenous nerve sometimes pierce the belly of the abductor hallucis muscle, leading to a connection with the medial plantar nerve by means of a small cutaneous branch. Iatrogenic injury to any of these nerves as in the case of tarsal tunnel release can lead to loss of sensation in the area of KI 5.

The tibial nerve and its distal branches may become entrapped at the medial ankle, producing a condition known as "tarsal tunnel syndrome" that leads to pain in the foot. It may cause neuropathic changes in tibial nerve branches coursing beneath KI 4 to KI 2, including the site of KI 5. Compression of the tibial nerve most commonly takes place at the level of the tarsal tunnel, especially in athletes.[6] Inflammation and/or space-occupying lesions affecting structures comprising the tunnel readily impact the tibial nerve due to the inelastic nature of this fibro-osseous canal. Surgical incisions designed to decompress the tarsal tunnel extend roughly from KI 7 to KI 6 (which includes KI 5); those patients who fail to respond to conservative treatment may require acupuncture, laser therapy, and/or massage to assist with healing not only the skin but also nerve function. Treatment would focus on "lining the scar" with needles inserted a small distance from the site of incision as well as releasing the connective tissue deep to the skin.

Treatment at KI 5 and nearby KI points helps release pressure on the nerve. In addition to acupuncture, massage and laser therapy play important roles in alleviating pain, tension, and neuropathy of the ankle and foot.

Vessels

- **Medial calcaneal artery:** Arises from the posterior tibial artery to supply the medial calcaneal area.

Clinical Relevance: Acupuncture, laser therapy, and other physical medicine measures improve circulation to the medial ankle by local and systemic means in the event of iatrogenic or other injury.[7,8,9]

Indications and Potential Point Combinations

- **Genitourinary problems (nephritis, nephrolithiasis, renal colic, kidney failure, difficult urination, menstrual pain or irregularities):** KI 5, KI 3, SP 6, SP 10, BL 23, BL 28, BL 32, BL 33, CV 3, CV 4,CV 6, GV 20.
- **Pelvic limb edema:** KI 5, KI 3, SP 6, SP 9, KI 16, SP 20.
- **Heel pain:** KI 5; check for trigger points in the soleus ("jogger's heel") at KI 7, the tibialis posterior ("runner's nemesis") near BL 55, and the gastrocnemius ("calf cramp muscle") near LR 7.
- **Achilles tendinopathy:** KI 4, KI 3, KI 5, BL 61, BL 60, plus trigger points in the muscular contributors to the calcaneal tendon: the gastrocnemius, the soleus, and the plantaris (BL 40). Add laser therapy and massage to support tissue health and repair.

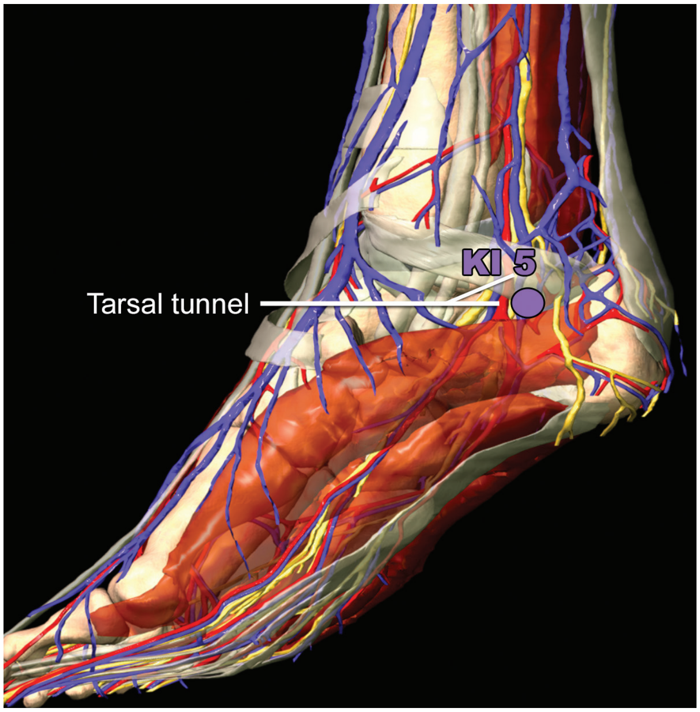

Figure 8-12. KI 5, "Water Spring", continues the water metaphor of previous points, including "Gushing Spring" (KI 1) and "Great Torrent" (KI 3). This image reveals the way in which needling KI 5 may address trigger points in the myotendinous junction of the abductor hallucis muscle. Trigger points here can produce intense medial heel pain that refer to KI 2 along the medial aspect of the foot. Too, compression of the tibial nerve (cranial to KI 5) beneath the flexor retinaculum causes tarsal tunnel syndrome. Patients with tarsal tunnel syndrome complain of paresthesia and burning dysesthesia along the medial foot, worse with walking and standing.[10]

- **Iatrogenic injury of the posterior neurovascular bundle during arthroscopy:** KI 5, KI 4, KI 6, BL 60, add laser therapy and massage to support recovery.

Evidence-Based Applications

- Acupressure at GV 4, GV 15, GV 20, BL 23, BL 28, BL 32, HT 7, HT 9, ST 36, SP 4, SP 6, SP 12, CV 2, CV 3, CV 6, KI 3, and KI 5 may be a suitable alternative to oxybutinin in the treatment of enuresis.[1]
- Acupuncture and electroacupuncture at ST 4, ST 7, LI 4, HT 7, SP 6, KI 5, and ST 36 induced an increase in the local blood flow in the skin over the parotid gland in patients with Sjögren's syndrome.[2]

KI 6

Zhao Hai "Shining Sea"

On the medial ankle, 1 cun below the tip of the medial malleolus.

Between the tibialis posterior tendon (anteriorly) and the flexor digitorum longus tendon (posteriorly).

Alternate location (KI 6'): Directly distal to the medial malleolus at the dorsal/plantar skin junction.

Tendons

- **Posterior tibialis tendon:** The posterior tibialis inverts the foot and provides ankle plantarflexion. The primary stabilizer of the medial longitudinal arch, the posterior tibialis muscle lefts the arch during plantarflexion. Other active stabilizers of the arch include the flexor hallucis longus and brevis muscles along with the abductor hallucis.[5] Passive support structures include the ligaments and fascia, including the plantar fascia, long and short plantar ligaments, and the spring ligament.
- **Flexor digitorum longus tendon:** The flexor digitorum longus flexes the lateral four pedal digits and plantarflexes the ankle. It helps support the longitudinal arch of the foot.
- **Abductor hallucis muscle:** Abducts the great toe.

Clinical Relevance: Dysfunction of the caudomedial soft tissues, including the posterior tibial tendon and flexor digitorum longus tendon, can lead to flattening of the medial arch of the foot, or pes planus.[6] Posterior tibial tendon dysfunction also leads to a shift of the center of gravity toward the heel and medial aspect of the foot. Tension and trigger point pathology of the medial foot frequently results in medial foot pain involving the abductor hallucis muscle. Trigger points in the abductor hallucis muscle in the vicinity of KI 6 refer pain strongly to the caudal calcaneus and extend to the medial foot at SP 3.

Whereas myofascial dysfunction of the abductor hallucis muscle responds quickly and dramatically to physical medicine maneuvers, compartment syndrome can constitute a surgical emergency. Compartment syndrome of the medial foot affecting the abductor hallucis muscle and neurovascular contents can follow surgery, fracture, crush injury, vascular insult, or even minor or unrecognized injury, especially in children.[7] Patients with compartment syndrome complain of the "7 P's", namely: pain, paresthesias, pulselessness, paralysis, pressure, pain with passive stretch, and induration with palpation.[8] Pain, out of proportion with the stimulus, may be the most sensitive clinical symptom.

Figure 8-13 compares the location of KI 6 and KI 6'. KI 6 lands between the flexor digitorum longus and tibialis posterior tendons; KI 6' relates more closely to the medial plantar nerve and vessels.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior

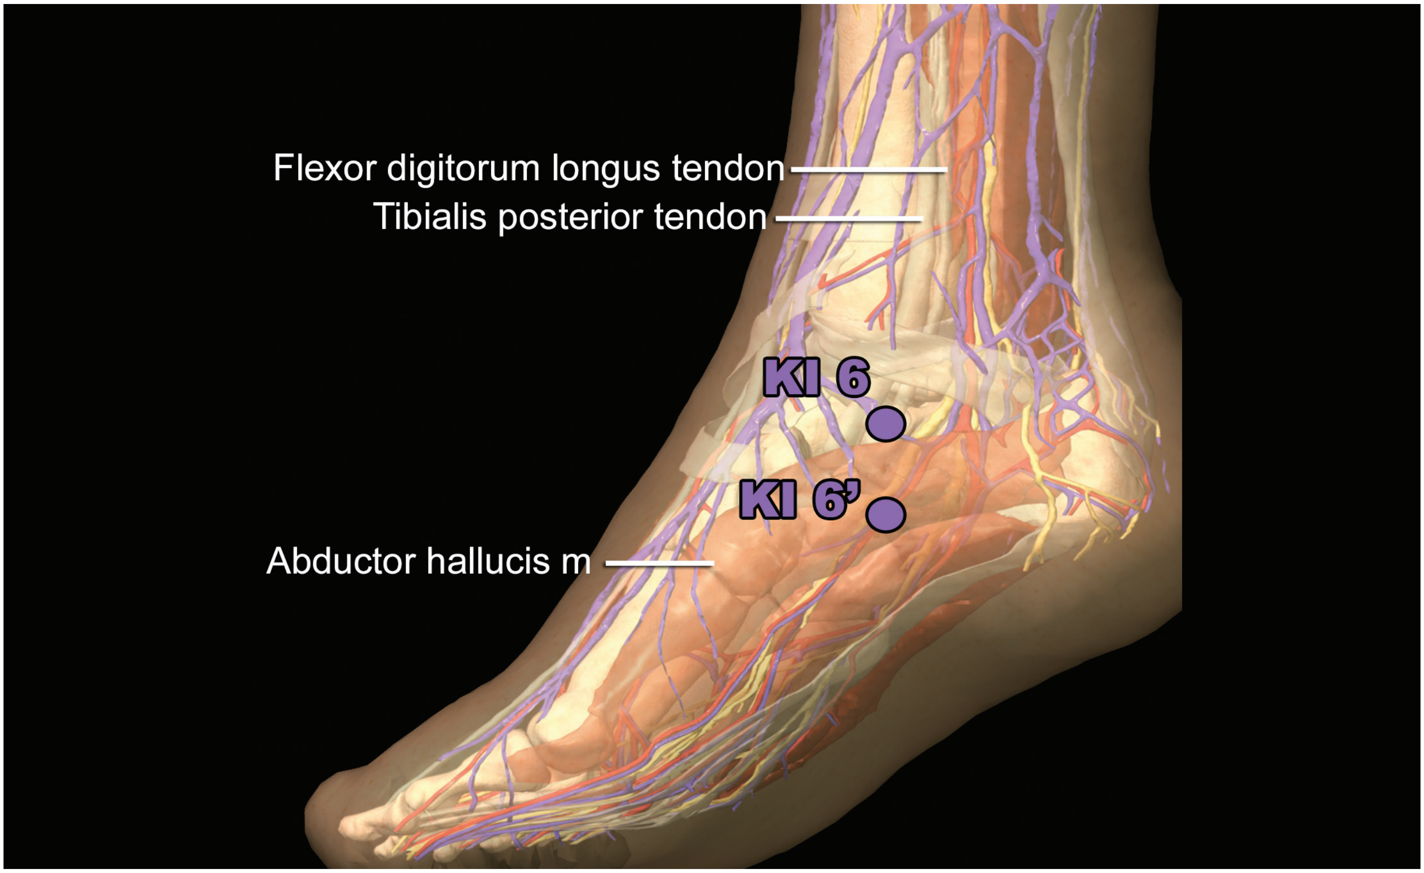

Figure 8-13. KI 6 associates with tendinous elements while KI 6' impacts the abductor hallucis muscle and the medial plantar vessels and nerve. Like Gushing Spring (KI 1), Water Spring (KI 5), and Great Ravine (KI 3), "Shining Sea" for KI 6 refers to the rich vascular supply of the medial foot and ankle.

aspect of the leg and knee. Posterior and inferior to the medial malleolus, the tibial nerve divides into the lateral and medial plantar nerves.

- **Medial plantar nerve (larger terminal branch of tibial nerve):** The medial plantar nerve supplies the skin on the medial aspect of the sole of the foot, as well as the sides of pedal digits I through III. The medial plantar nerve supplies the following muscles: abductor hallucis, flexor digitorum brevis, flexor hallucis brevis, and the first lumbrical muscle.

Clinical Relevance: Figure 8-6 depicts and compares the courses of the medial and lateral plantar nerves and vessels; these neurovascular components appear again in Figure 8-13, unlabeled. Tension and contracture of the abductor hallucis muscle can compress the nerve, causing numbness, tingling, cramping, and burning pain on the plantar foot at the metatarsal heads and possibly the heel.[9] Symptoms of tarsal tunnel syndrome, which this condition is called, worsen with weight bearing and pressure applied to the tunnel. They improve with both rest and elevation of the foot. On neurologic examination, sensory examination may reveal reduction in two-point discrimination and vibratory perception of the great toe. Some patients report a history of surgical release for plantar fasciitis with insufficient relief; these individuals may have been experiencing plantar nerve compression misdiagnosed as plantar fasciitis. While surgical release of the tarsal tunnel serves as one option, many patients would prefer conservative approaches to reduce myofascial restriction if given the option.

Tibial nerve compression in the tarsal tunnel causes neuropathy that, in diabetic patients, can increase risk of pedal ulceration, pain, and sensory loss.[10] This may affect nerves coursing through KI 6.

Branches of the tibial nerve, including the medial plantar nerve, can also experience compression during compartment syndrome in the foot. Crush injury of the foot commonly increases pressure in the foot compartments. Compression of the structures coursing through the calcaneal compartment predisposes patients to claw toes secondary to contracture of the quadratus plantae muscle.[11] Entrapment of the medial plantar nerve as it courses through the calcaneal tunnel may follow, perhaps leading to hallux varus as a complication.

Vessels

- **Medial plantar artery:** This small artery mainly supplies the muscles of the great toe, but most of the plantar digital arteries arise from the medial plantar artery. Its superficial branch provides circulation to the skin on the medial aspect of the sole. This branch gives off digital branches which accompany the medial plantar nerve's digital nerve branches.
- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.

Clinical Relevance: Diabetes mellitus decreases the density of perivascular nerve fibers and the reactivity of vascular muscles in plantar metatarsal arteries.[12] This raises consideration of neuromodulation through acupuncture, laser therapy, and massage to exogenously improve circulation through similarly compromised vessels.

Reflux in foot veins is associated with venous toe and forefoot ulceration.[13] Although ulceration typically affects the dorsum of the toes and forefoot, pressure changes secondary to forces affecting the arch as well as contraction of the triceps surae muscles (i.e., gastrocnemius and soleus muscles) contribute to venous drainage of the foot and ankle. Neuromodulation and circulatory balance provided by acupuncture, massage, and laser therapy should improve venous drainage and tissue maintenance.

Compartment syndrome of the medial foot may result in increased venous and capillary pressures due to venous outflow obstruction.[14] Arterial blood has difficulty entering the fixed space, causing ischemia that compromises the integrity of capillary walls. As permeability of the walls increase, edema, hypoxia, and acidosis take hold. Complications such as nerve and muscle dysfunction ensue after three hours of ischemia. Damage to nerves may become irreversible after 12-24 hours, about the time that muscle contracture begins. While awaiting or considering urgent fasciotomy, treatment with laser therapy may aid tissue health. However, given the urgency required for surgical treatment, practitioner should not delay proper diagnosis or treatment of compartment syndrome in order to wait and see if physical medicine treatments help over the course of several days.

Pseudoaneurysm of the medial plantar artery may follow trauma, iatrogenic vascular intervention, or intravenous drug administration.[15] Although pseudoaneurysm of the lateral plantar artery more commonly occurs, it can afflict the medial vessel in cases of ankle sprain, penetrating injury, iatrogenic causes such as arthroscopy and fracture fixation, and contusion. Patients exhibit pain, swelling, and hematoma from the trauma, the pseudoaneurysm, or both. Left untreated, pseudoaneurysms may either resolve spontaneously or grow gradually and compress the local neurovascular structures. When a pseudoaneurysm falls in the vicinity of KI 6, tibial nerve compression and tarsal tunnel syndrome may result. Whether surgical or nonsurgical means are employed to address the vascular damage, acupuncture, laser, and massage can improve nerve function and circulation, allowing the patient to recover more fully.

Indications and Potential Point Combinations

- **Local pain or dysfunction:** KI 6 for medial ankle pain; KI 6' for medial foot pain. Search for additional trigger points related to the referred pain distribution.
- **Dysphonia:** KI 6, ST 9, LU 7, SI 3, BL 60.

Evidence-Based Applications

- Case report indicated KI 6 was useful for the treatment of **chronic laryngitis, pharyngitis, nocturnal epilepsy, costochondritis, and upper palpebral ptosis.**[1]
- Acupuncture at KI 6, ST 9, LU 7, BL 60, and SI 3 offered an effective alternative treatment for **hyperfunctional dysphonia,**

bolstering findings that acupuncture can serve as an effective adjunctive support for the treatment of **voice disorders** without the invasiveness or concomitant adverse effects of surgical or medical management.[2]

- Both laser and needle acupuncture at GB 1, BL 2, ST 5, Yintang, LI 4, SI 3, LR 3, KI 6, and TH 5 worked equally well in improving objective measurements of **keratoconjunctivitis sicca (KCS).**[3]
- Of the following group of points, 12 were chosen according to the Chinese medical assessment of men with **poor quality sperm.** Following a series of acupuncture treatments, their fertility index increased significantly, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. The acupuncture points from which the 12 were selected included: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[4]

KI 7

Fu Liu "Returning Current" or "Recover Flow"

2 cun proximal to KI 3, in the first depression along the cranial border of the calcaneal tendon appreciated when palpating from KI 3 proximad.

Figure 8-14 contrasts the locations of KI 3, KI 7, and KI 8.

Muscles and Tendons

- **Flexor hallucis longus muscle:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It assists ankle plantarflexion.
- **Plantaris tendon:** Weakly assists the gastrocnemius muscle in plantarflexing the ankle and in flexing the knee. The plantaris muscle contains an exceptionally high density of proprioceptive endings that confer the ability to relay feedback about position of the foot to the central nervous system. As such, it may act more as an adjunct stabilizer for the foot and ankle. The plantaris tendon, supplied by the tibial nerve, attaches blends with the calcaneal tendon or inserts separately to the medial aspect of the calcaneus.
- **Calcaneal (Achilles) tendon:** The common tendon of the "triceps surae" muscle, which includes the two-headed gastrocnemius muscle and the soleus muscle. May incorporate the plantaris tendon.

Clinical Relevance: Pain in the great (big) toe and 1st metatarsal may arise from trigger point pathology in the vicinity of KI 7. Note the prominence of the flexor hallucis longus in the cross-section of Figure 8-17. Palpate firmly and deeply in this region to fully examine the distal crus for the presence of myofascial dysfunction requiring treatment to fix foot and calf problems.

The plantaris muscle or tendon can be impacted by excessive traction applied to the site as in over-vigorous stretching, jumping, or running. It may suffer collateral damage in a calcaneal tendon rupture. Also, while the plantaris tendon may contribute to "tennis leg", a calf injury identified by a "snapping" in the mid-calf during strenuous exercise, it appears that tennis leg may more commonly arise from a rupture of the medical head of the gastrocnemius muscle at its tendinomuscular junction.[2] Surgical procedures that remove the plantaris tendon for reconstruction elsewhere or because direct trauma, pain, and swelling have injured the tendon, remove the ability of the plantaris to assist in foot placement and ankle stability by dint of its proprioceptive function. As such, acupuncture and related techniques that address pain and swelling in an injured plantaris tendon or directly treat joints elsewhere making its removal

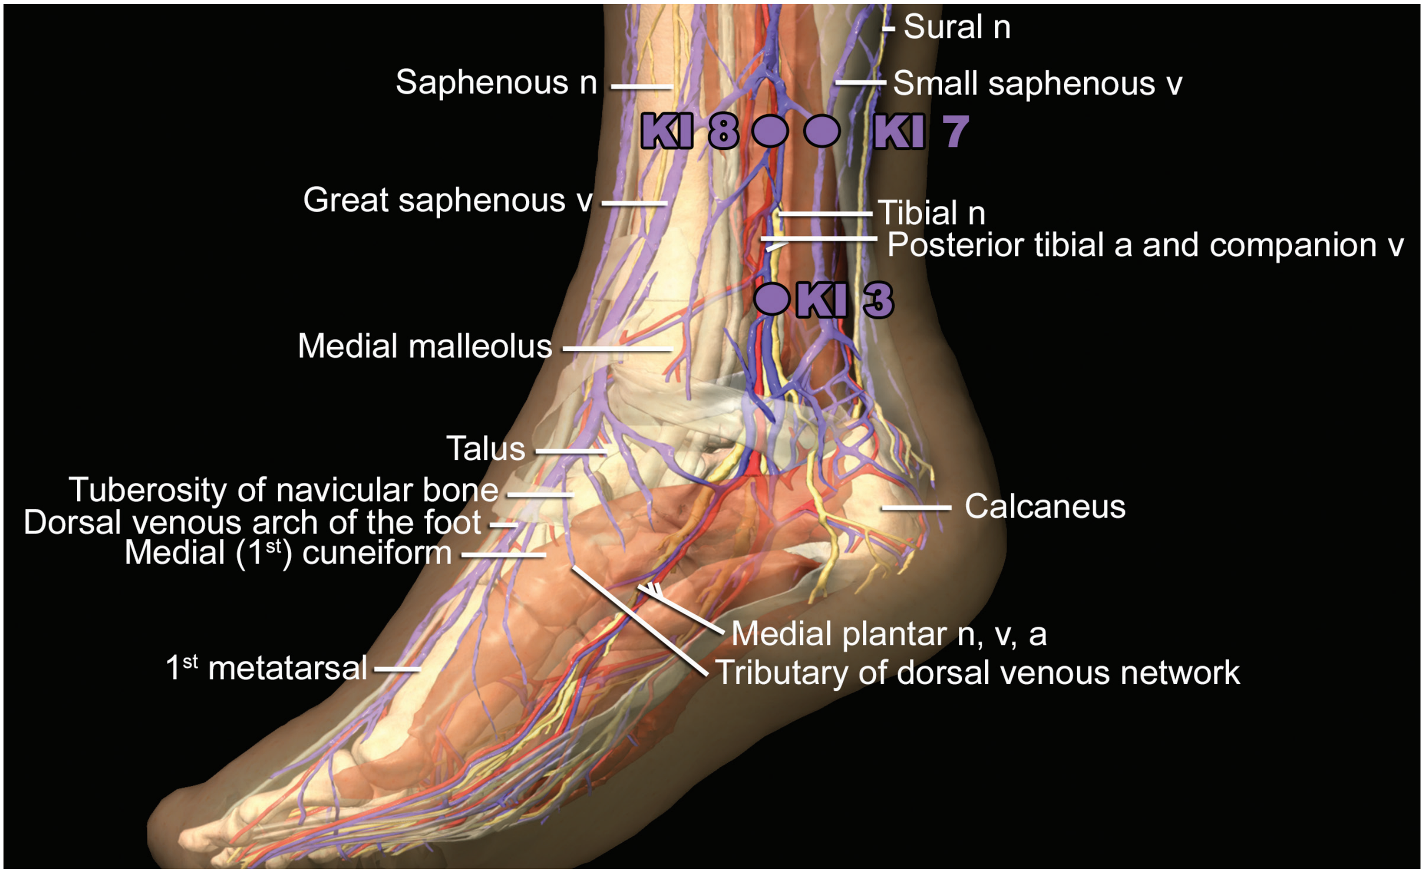

Figure 8-14. This image elucidates the basis of the name "Recover Flow" or "Returning Current" for KI 7. First, the sural nerve that related to the BL channel on its lateral aspect is now touching the KI channel. Thus, the channel "flow" returns to meet the sural nerve, having migrated from BL to KI. In addition, KI 7 represents the first point along the KI channel to associate with predominantly venous territory, rather than coupled arteries and veins. Thus, the blood referenced by "flow" and "current" pertains to venous blood returning to the heart. Indications for KI 7 associated with alleviating edema and encouraging fluid movement arise from both the small saphenous venous network deep to KI 7 and the autonomic nerve fibers accessible in this area.

for reconstruction unnecessary can help patients maintain the structural integrity of their original design.

Calcaneal tendon rupture can become a recurring problem because the tendinous tissue has a high degree of disorganization. Pulsed low level laser therapy remodels tissue and improves tendon healing by increasing matrix metalloproteinase activity and collagen synthesis.[3] Quinolones may also injure the calcaneal tendon, perhaps through ischemic processes, oxidative damage, and direct collagen toxicity.[4] Patients with calcaneal tendinopathy exhibit pain, swelling, and possibly crepitus at the tendon.[5] Points associated with the calcaneal tendon include KI 4, KI 3, KI 7, BL 59, BL 60, and BL 61. Acupuncture improves blood circulation and healing to the tendon through systemic/generalized effects.[6] Laser therapy also facilitates tendon recovery through circulatory support and anti-inflammatory means.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (L5-S2 and sometimes S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, Plantaris, and the posterior tibialis muscle, as well as the other muscles in the caudal aspect of the leg and knee.

Clinical Relevance: Tibial nerve branches may differ in terms of the spinal cord segments from which they originate. For example, S1 and S2 course in the tibial nerve branches to the gastrocnemius, soleus, and plantaris. L4 and L5 supply the tibialis posterior, while L4, L5, and S1 course to the popliteus. S2 and S3 supply the flexor hallucis longus and flexor digitorum longus. Thus, when employing points innervated by the tibial nerve for somatovisceral influence (e.g., when treating voiding dysfunction), more distal structures receive more caudal spinal segmental supply (i.e., from sacral cord segments). Considering their sacral innervation and higher sympathetic nerve density, distal points may confer greater impact on genitourinary complaints than those at the proximal calf and knee.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.

Clinical Relevance: After calcaneal tendon injury, acupuncture and hyperthermia may improve microcirculation in local vessels supplying the tendon whose blood flow promotes repair and recovery of function.[7,8] Laser therapy and massage also provide improved blood flow to tendons.

Indications and Potential Point Combinations

- **Urinary problems, including cystitis, pain:** KI 7, KI 3, SP 6, BL 28, BL 32, CV 2, CV 3.
- **Reproductive problems, including orchitis, infertility, erectile dysfunction, menstrual irregularity:** KI 7, SP 6, SP 10, ST 30, BL 23, GV 3, CV 4.
- **Low back pain:** KI 7, BL 40, BL 60, BL 23, local trigger points on the back.
- **Edematous ankles:** KI 7, SP 6, SP 9, SP 10, SP 12, CV 6. Add massage and laser therapy to promote resolution of edema.

Evidence-Based Applications

- Of the following group of points, 12 were chosen according to the Chinese medical assessment of men with **poor quality sperm.** Following a series of acupuncture treatments, their fertility index increased significantly, following improvements in the parameters of total functional sperm fraction, percent viability, total motile spermatozoa per ejaculate, and integrity of the axonema. The acupuncture points from which the 12 were selected included: LU 7, LI 4, LI 11, ST 30, ST 36, SP 6, SP 9, SP 10, HT 7, BL 20, BL 23, BL 33, KI 6, KI 7, PC 6, LR 5, LR 8, CV 1, CV 2, CV 4, CV 6, and GV 4.[1]

KI 8

Jiao Xin "Intersection Reach"

On the medial aspect of the leg, caudal to the tibia, 2 cun proximal to KI 3. Approximately 0.5 cun cranial to KI 7.

Muscles

- **Posterior tibialis muscle:** This muscle inverts the foot and provides ankle plantarflexion.
- **Flexor hallucis longus muscle:** The flexor hallucis longus muscle supports the medial longitudinal arches of the foot. It flexes the great toe at each of its joints. It assists ankle plantarflexion.
- **Flexor digitorum longus muscle:** The flexor digitorum longus flexes the lateral four pedal digits and plantarflexes the ankle. It helps support the longitudinal arch of the foot.

Clinical Relevance: Called the "runner's nemesis", the posterior tibialis muscle triggers pain in the sole of the foot and calcaneal tendon; it worsens when running on uneven surfaces. Pain may also extend to the midcalf and heel.

The flexor digitorum longus and flexor hallucis longus muscles, i.e., long flexors of the toes, earn the name "clawtoe muscles" because contracture of these muscles lead to hammer toe and clawtoe.

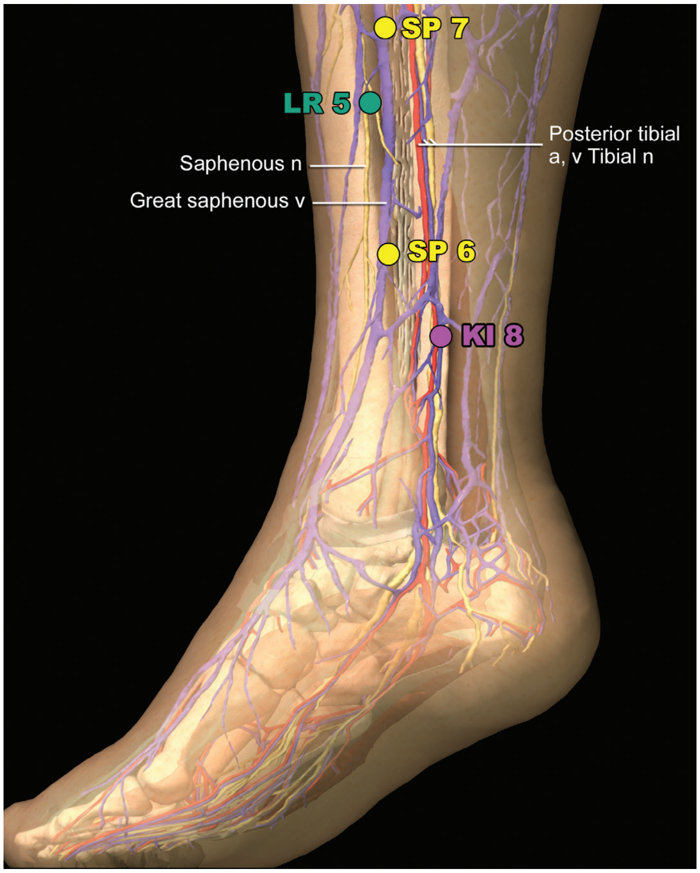

Figure 8-15. KI 8, the "Intersection Reach" follows the posterior tibial artery and vein as well as the tibial nerve, similar to KI 3. In contrast, the nearby great saphenous vein accompanies the SP line.

Nerves

- **Tibial nerve (L5-S3):** Innervates the flexor digitorum longus muscle, the flexor hallucis longus muscle, and the posterior tibialis muscle, as well as the other muscles in the posterior aspect of the leg and knee. At about KI 8 and SP 6, the tibial nerve occupies the location known as the "high tarsal tunnel".[1] Nerve compression can result from myofascial restriction involving the flexor digitorum longus and flexor hallucis longus, the soleus, and tibialis posterior.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.

Clinical Relevance: Women treated with percutaneous tibial nerve stimulation for overactive bladder syndrome may experience a transient sensory deficit in the region of great toe and 1st metatarsophalangeal joint. Acupuncture along the SP and KI lines may aid in the recovery of sensory nerve function in the tibia.[2] In addition, acupuncture noninvasively stimulates the tibial nerve without causing sensory dysfunction afterward in most cases.

The fact that sacral spinal segments contribute significantly to the fiber composition of the tibial nerve helps explain why distal tibial nerve points may be more successful at neuromodulating pelvic organ function than medial thigh or knee locations, and why these points appears so often in needling protocols for genitourinary concerns and voiding dysfunction. In particular, segments supplying the tibial nerve as it innervates the flexor hallucis longus and flexor digitorum longus arise from S2 and S3, the most caudal segments associated with the tibial nerve. Thus, stimulation of KI 8 for voiding dysfunction should be considered, along with SP 6 and KI 3.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins by the union of the dorsal vein of the great toe and the pedal dorsal venous arch. It anastomoses with the small saphenous vein and empties into the femoral vein.
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin off of the superficial veins. When they do so, they travel at an oblique angle so that muscular contraction and pressure within the compartment compresses the perforating veins. This phenomenon assists in encouraging unidirectional blood flow from superficial to deep veins and enables muscular contraction to assist in returning venous blood toward the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable

Figure 8-17. KI 8, like KI 3, KI 5, KI 6′, and KI 1, closely relates to the tibial nerve, as shown in this cross-section. This means, then, that many of the systemic indications of these points overlap. Myofascial pain problems, on the other hand, require identification and treatment of specific of trigger points. KI 8 needling would more likely target the flexor hallucis longus trigger point than the typical location for trigger points in the flexor digitorum longus, typically located in the proximal calf.

relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[3]

From a therapeutic perspective needling points along the caudal tibia may activate nervi vasorum of local vasculature, conferring autonomic neuromodulatory benefits affecting genitourinary organ function and circulation.

Indications and Potential Point Combinations

- **Regulates blood supply to the pelvic limb, especially to the foot:** KI 8, SP 6, LR 3.
- **Irregular menstruation, amenorrhea, menorrhagia, metrorrhagia, uterine prolapse:** KI 8, KI 3, SP 6, CV 2.
- **Urinary hesitancy or retention, voiding dysfunction:** KI 3, KI 8, SP 6, BL 39, BL 33, BL 32, BL 28, CV 3.

Evidence-Based Applications

- **Effects on the brain:** Acupuncture at KI 8 affect brain areas involved with pain modulation as well as the hippocampus and insula.[4] This supports an indication for analgesia.[5] Acupuncture at KI 8 also inspires a stronger interplay between the default mode network (DMN), the hippocampus, and the insula. The DMN consists of cortical midline structures and lateral parietal regions involved in analgesia. Improved communication between the DMN, involved in self-projective thinking, and the periaqueductal gray (analgesia), the anterior cingulate cortex and amygdala (affective processing), and the hippocampus (memory) fosters integration between “neural dimensions of inner life” and “psychophysical pain homeostasis”.[6] In addition, stimulation of KI 8 also activated the visual cortex spatial domain but in an opposite direction from GB 37 in the resting state after acupuncture.[7]

KI 9

Zhu Bin "Expel Attack"

On the medial aspect of the leg, in a depression approximately 5 cun proximal to KI 3, on the line adjoining KI 3 and KI 10. About 1 cun caudal to the tibial border and approximately level with LR 5.

Muscles

- **Gastrocnemius tendon:** The gastrocnemius muscle raises the heel during ambulation. It flexes the leg at the knee, and plantarflexes the ankle if the knee is extended.
- **Soleus muscle:** Steadies the leg on the foot and plantarflexes the ankle, regardless of the position of the knee.

Clinical Relevance: KI 9 coincides with the soleus trigger point that refers pain proximal to the caudomedial calf and strongly along the medial calcaneal tendon, the entire heel, and the plantar aspect of the foot toward KI 1. Gastrocnemius trigger points typically occur further proximal, but echo the referred pain distribution of the soleus muscle.

Nerves

- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Tibial nerve (S1, S2):** This branch of the sciatic nerve supplies the soleus, gastrocnemius, plantaris, and popliteus muscles.

Clinical Relevance: At about KI 9, the tibial nerve occupies the location known as the "high tarsal tunnel".[1] Nerve compression can result from myofascial restriction involving the flexor digitorum longus and flexor hallucis longus, the soleus, and tibialis posterior, as illustrated by the cross-section of Figure 8-19. Tibial nerve entrapment produces gastrocnemius muscle atrophy as well as paresthesia and pain from the neuropathy that ensues.

Vessels

- **Posterior tibial artery:** Arises from the popliteal artery. Supplies blood to the posterior and lateral compartments of the leg. Its circumflex fibular branch joins the genicular anastomoses. The posterior tibial artery provides a nutrient artery to the tibia.
- **Posterior tibial vein:** Perforating veins carry blood from the great saphenous vein to the posterior and fibular (peroneal) veins.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins by the union of the dorsal vein of the great toe and the pedal dorsal venous arch. It anastomoses with the small saphenous vein and empties into the femoral vein.
- **Perforating veins:** These veins contain valves that allow flow from the superficial to the deep veins. Perforating veins pass through deep fascia close to their origin off of the superficial veins. When they do so, they travel at an oblique angle so that muscular contraction and pressure within the compartment compresses the perforating veins. This phenomenon assists in encouraging unidirectional blood flow from superficial to deep veins and enables muscular contraction to assist in returning venous blood toward the heart, against the force of gravity.

Clinical Relevance: Stripping of the great saphenous vein may injure the saphenous nerve, leading to sensory dysfunction along the medial calf. The two structures have a close but variable relationship, making iatrogenic injury of the latter a complication of endovenous laser therapy and radiofrequency ablation.[2]

From a therapeutic perspective needling points along the caudal tibia may activate nervi vasorum of local vasculature, conferring autonomic neuromodulatory benefits affecting genitourinary organ function and circulation.

Treatment of KI 9 with acupuncture, laser therapy, and/or massage may bolster circulation to the myotendinous junction of the calcaneal tendon, fostering tissue repair and connective tissue regrowth.

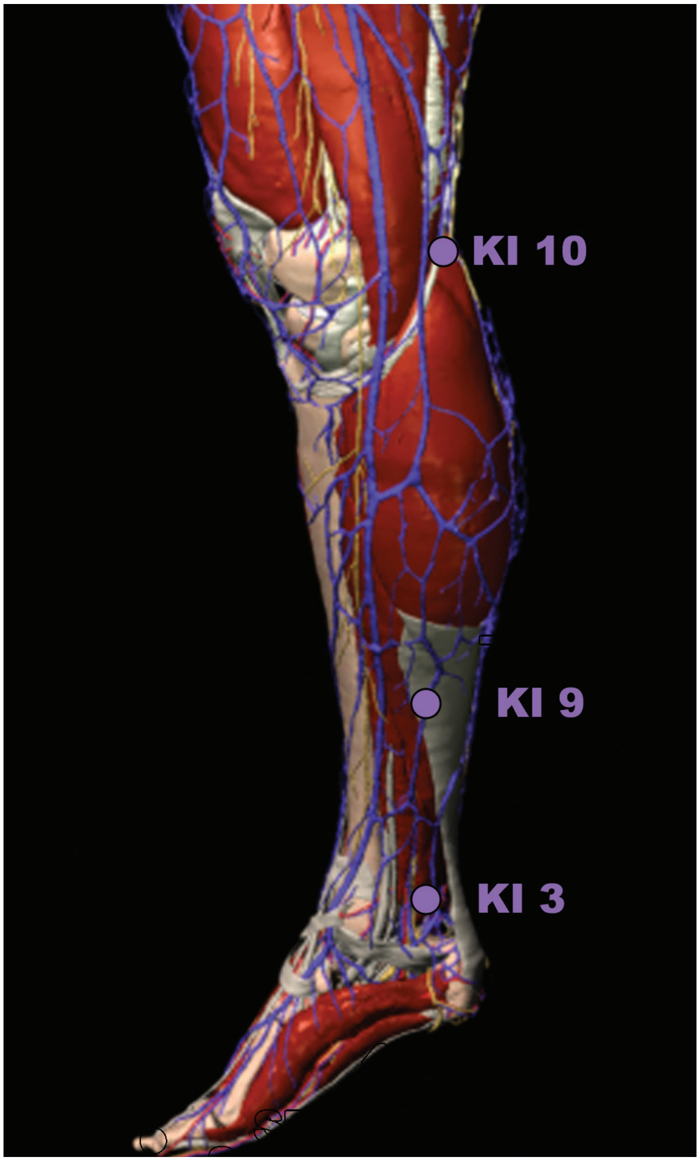

Figure 8-18. KI 9 falls along the line connecting KI 10 and KI 3. As the "Expel Attack" point, KI 9 can supposedly expel pathogenic influences. Perhaps by strengthening the power of the leg and alleviating pain in it, the leg itself becomes more capable of fending off an attack. More likely, the affliction that KI 9 repels pertains more to cramps in the calf caused by the gastrocnemius and soleus muscles.

KI 10

Yin Gu "Yin Valley"

At the medial end of the popliteal fossa, level with BL 40, between the tendons of the semitendinosus and semimembranosus muscles. Locate with the knee slightly flexed.

Tendons

- **Semimembranosus tendon:** Flexes the leg. Extends the thigh. When the knee alone is flexed, the semimembranosus muscle rotates the leg medially. When the thigh *and* leg are flexed, the semimembranosus extends the trunk. The main tendinous head inserts directly onto the caudomedial tibial plateau just caudal to the medial collateral ligament. The pars reflexa, the most cranial insertion, passes beneath the medial collateral ligament to insert on the tibia just distal to the medial joint line. Other insertions include the caudal aspect of the medial femoral condyle and the fascia of the popliteus muscle.
- **Semitendinosus tendon:** Flexes the leg. Extends the thigh. When the knee alone is flexed, the semitendinosus muscle rotates then leg medially. When the thigh *and* leg are flexed, the semitendinosus extends the trunk.

Clinical Relevance: Travell & Simons dub the hamstring muscles "chair-seat victims" due to the common finding of pain in patients who compress their hamstring muscles and sciatic nerve on the edge of a chair, thereby compromising circulation and compressing nerves. The mid-portion of the caudal thigh can harbor an abundance of trigger points in the mid-bellies of the semimembranosus, semitendinosus, and biceps femoris muscles. Pain refers from these sites either to the transverse gluteal fold or the popliteal fossa.

Semimembranosus tendinopathy, one of several potential sources of caudomedial knee pain, typically leads to a progressive ache that begins insidiously.[3] The pain may jump in intensity if the individual suddenly increases the amount of repetitive endurance activity such as running or bicycling. The pain of semimembranosus tendinopathy often localizes to the main insertion at the caudomedial knee; it may radiate proximad to the caudomedial thigh or distad to the medial calf. Pain worsens with activation of the muscle, as when walking downstairs, deeply flexing the knee, or performing the same activities that cause it to worsen, which require repetitive contractions.

Myofascial evaluation reveals tenderness to palpation of the semimembranosus tendon at its tibial insertion (SP 9) or more proximal (KI 10). Maneuvers that activate or stretch the tendon worsen the pain.

Differential diagnoses of caudomedial knee pain include tearing of the medial meniscus, osteoarthritis, pes anserine bursitis or associated tendinopathy, popliteal (Baker's) cyst, gastrocnemius strain affecting the medial head, popliteus strain, sprain of the medial collateral ligament, and more. Tendinopathy of the semimembranosus may develop in any of its insertions where the tendon experiences increased friction where it abuts or attaches to other structures. Repetitive, eccentric tendon loading can also induce degenerative changes in the tendons, the insertions, or the U-shaped bursa that surrounds the distal semimembranosus tendon and cushions it from the medial tibial plateau, the medial collateral ligament, and the semitendinosus muscle.

Conservative treatment for semimembranosus tendinopathy includes acupuncture, massage, laser therapy, hamstring stretching and strengthening exercises, shoe fit evaluation to avert over-pronation, and anti-inflammatory medications or phytomedicinals as needed.

"Snapping knee syndrome" in the caudomedial aspect of the tibia can involve dysfunction of the semitendinosus and gracilis tendons.[4]

Nerves

- **Posterior femoral cutaneous nerve (S1-S3/S4):** Supplies the skin of the posterior thigh and popliteal fossa. May receive contributions from the inferior (caudal) gluteal nerve, the common peroneal (fibular), and the sciatic/tibial nerves (with which it may communicate through nerve branching).[5] The posterior femoral cutaneous nerve gives rise to the inferior (caudal) cluneal and perineal branches that supply the caudal buttock and lateral perineal regions, the proximal medial thigh, caudolateral scrotum/labium majus, and a portion of the clitoris and penis. The posterior femoral cutaneous nerve accompanies the small saphenous vein to the mid-calf and joins with the sural nerve by means of communicating branches. Thus, in addition to the territory described by the sciatic nerve, the posterior femoral cutaneous nerve also supplies a neuroanatomic basis for the BL channel with overlap onto the KI pathway. Figure 8-21 elucidates

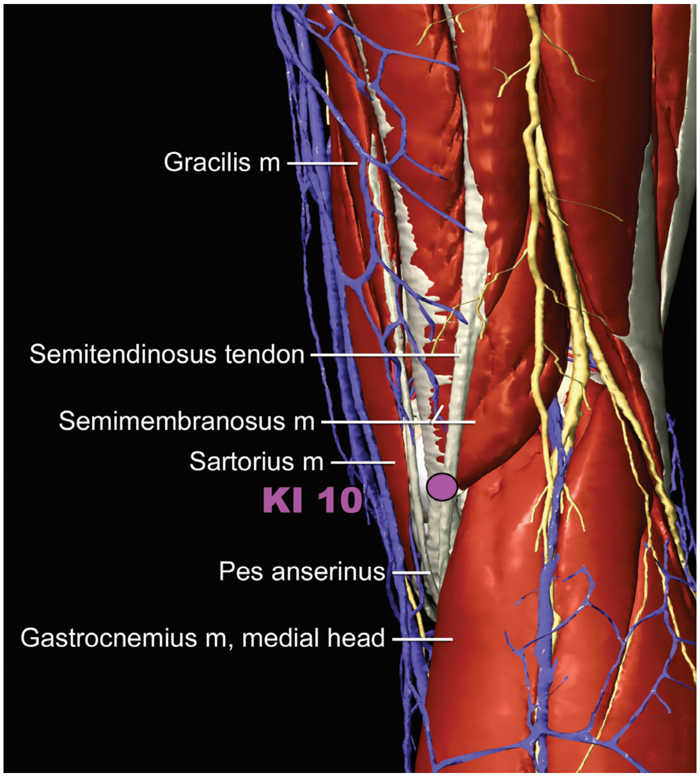

Figure 8-20. KI 10, in the "Yin Valley" at the medial aspect of the knee, forsakes the tibial nerve for the Yin, or inner, surface of the knee. Not to worry, as the BL channel partners with both branches of the sciatic nerve with BL 39 for the common peroneal and BL 40 for the tibial nerve, as shown in Figure 8-21. After all, the BL line demonstrated its commitment to the sciatic from its inception.

Figure 8-21. KI 10 ("Yin Valley"), BL 40 ("Bend Middle" or "Middle of the Crook"), and BL 39 ("Bend Yang" or "End of the Crook") line up along the popliteal crease. This image reveals significant anatomy deep to each point.

the way in which a small branch from the posterior femoral cutaneous nerve, proximal to BL 40, takes a medial detour toward KI 10.

- **Anterior branch of the medial femoral cutaneous nerve (L2-L4):** Supplies the skin on the anterior and medial thigh regions.
- **Saphenous nerve (from the femoral nerve, L2-L4):** Innervates the skin on the medial aspects of the leg and foot.
- **Sciatic nerve (L4-S3):** Supplies the hamstring muscles (i.e., the semimembranosus, semitendinosus, and long head of the biceps femoris muscles) by its tibial division (L5-S2). (The short head of the biceps femoris muscle is supplied by the common peroneal (fibular) division (L5-S2).)

Clinical Relevance: Somatic afferents from the posterior femoral cutaneous nerve participate in a somato-bladder inhibitory reflex, supporting the incorporation of neuromodulation through KI 10 (and BL 40) for the treatment of urinary incontinence.[6] Thus, three avenues of neuromodulation work in alone or in concert to aid in micturition disorders, i.e., posterior femoral cutaneous (KI 10, BL 40), pudendal (CV 1), and sacral nerve pathways (BL 27-34).

The posterior femoral cutaneous nerve can become damaged by direct trauma secondary to intragluteal injection, wherein the patient reports loss of sensation of the caudal thigh and caudomedial gluteal region by dint of the caudal medial cluneal nerve also being affected. Compressive neuropathies affecting the posterior femoral cutaneous nerve result from prolonged bicycle riding, hematoma or tumor compression of the presacral region, and falls. Because the posterior femoral cutaneous nerve follows the BL, more than the KI, channel so closely, neuromodulation would similarly follow that trajectory along the caudal thigh, adding distal points at BL 40, BL 55, and BL 60, with reinforcement by means of KI 10 and KI 3.

The saphenous nerve and the nerve to the vastus medialis provide the main sensory contributions from the femoral nerve to the knee.[7] The adductor-canal-blockade is an analgesic measure to provide pain relief following total knee arthroplasty. When performed at the mid-thigh, this block produced signs of injury to the infrapatellar branch of the saphenous nerve in 84% of patients. These individuals either displayed altered sensations to a brush stimulation, inability to discriminate between cold and warmth, and/or inability to discern between blunt and sharp stimulation to the site. As KI 10 falls within part of the territory supplied by the saphenous nerve, injury to the nerve following this or other procedures may resolve more quickly with the added interventions of acupuncture and related techniques.

Saphenous neuritis causes pain and arises when the saphenous nerve becomes irritated or compressed, usually at the adductor canal or elsewhere along its course.[8] Surgical or non-surgical trauma to the medial or cranial knee can inflame the saphenous nerve, imitating medial meniscal tear or osteoarthritis in the joint. Unrecognized, this condition complicates treatment and confuses the clinical picture. It may accompany patellofemoral pain syndrome and degenerative conditions of the knee. Palpation of the nerve and acupuncture or other physical medicine maneuvers designed to address nerve compression and irritation not only lends insight into the true cause(s) of patients' complaints, but also aids them in avoiding invasive procedures that they may not need.

Saphenous nerve entrapment involving the infrapatellar branch is a frequently overlooked and under-diagnosed source of knee pain.[9] Entrapment often involves compression by the sartorius muscle; conservative measures should be initiated before severing part of the sartorius surgically, as has been previously advised.[10]

Located at the myotendinous junction of the semimembranosus muscle, KI 10 neuromodulates Golgi tendon organs attached to the tibial portion of the sciatic nerve. Each Golgi tendon organ, interwoven in the collagen fibrils of the tendon, connects with one end to the muscle fibers and with the other end to the tendon. Supplied by a Group Ib sensory nerve fiber, the tendon organ transmits information about the degree of muscle stretch and tension. It also informs the spinal cord about how much the muscle it attaches to is contracting, by means of action potential volleys sent through the large diameter, heavily myelinated axon, the Group Ib fiber. Reflexes in the spinal cord then create autogenic inhibition; i.e., relaxation of the same muscle. In this case, needling KI 10 should promote relaxation of the semimembranosus muscle.

Vessels

- **Inferior medial genicular artery:** The inferior medial genicular artery participates in the formation of the genicular anastomoses – a network of vessels around the knee. It does so with the help of the other genicular arteries, including the lateral superior, medial superior, and lateral inferior arteries and three additional contributors: the descending genicular branch of the femoral artery, the descending branch of the lateral femoral circumflex artery, and the anterior recurrent branch of the anterior tibial artery. Genicular branches of the popliteal artery also supply the knee joint capsule and the ligaments of the knee.
- **Popliteal artery:** Muscular branches of the popliteal artery supply the hamstring and gastrocnemius muscles, as well as the soleus and plantaris muscles.
- **Great saphenous vein:** This superficial, large vein courses along the medial aspect of the leg and thigh. It begins by the union of the dorsal vein of the great toe and the pedal dorsal

Figure 8-22. KI and BL lines exhibit a long-lasting Yin-Yang relationship, as the other six channel pairs likewise demonstrate. As previously described, the Yin-Yang relationship translates into the way the Yin channel occupies the inner, more vulnerable aspect of a body part while the Yang partner courses over the outer, more protected surface of the same anatomy, whether limb or trunk. For KI-BL, KI remains situated on the plantar and medial surfaces of the pelvic limb while BL landed on the dorsal and lateral aspects. When KI and BL move to the trunk, KI (KI 11) will take the ventral course. BL maintains its affinity for the dorsum.

Figure 8-23. KI 10 relates to the tendons of the semimembranosus and semitendinosus muscles. Trigger points in these hamstrings muscles, the "chair seat victims" groups per Travell and Simons, refer strongly to the gluteal crease. The referred pain pattern extends through KI 10 to the KI 9 level.

venous arch. It anastomoses with the small saphenous vein and empties into the femoral vein.

- **Medial inferior veins of the knee:** One of several deep veins around the knee that drain into the popliteal vein.

Clinical Relevance: Pseudoaneurysms sometimes develop after orthopedic surgery. In the case of anterior cruciate ligament reconstruction, arteries affected include the medial inferior genicular artery and popliteal artery.[11] When acute, these vascular lesions can cause sudden bleeding into the joint cavity. Acute and voluminous hemarthrosis usually presents with a pulsatile mass within the first few weeks after surgery, although a pseudoaneurysm may develop after ten weeks. Their growth may compress nerves and nearby veins, potentially leading to deep vein thrombosis and occasionally amputation. Pseudoaneurysms differ from true aneurysms by not involving all layers of an artery, but they still maintain internal arterial flow. Pseudoaneurysms occur more frequently following total knee arthroplasty, but also after several other types of orthopedic interventions, including arthroscopic meniscectomy and the aforementioned anterior cruciate ligament reconstruction.

The popliteal artery is susceptible to damage during posterior cruciate ligament reconstruction, though certain approaches offer more protection to the vessels than do others.[12,13]

In such cases of vascular damage, treatment of the region at and around KI 10 and the entire popliteal fossa improve blood supply and drainage.

Indications and Potential Point Combinations

- **Renal problems, including nephritis and renal colic:** KI 10, KI 3, BL 23, BL 52, GB 25.
- **Urinary problems, including cystitis, urinary hesitancy, voiding dysfunction:** KI 10, SP 6, BL 28, BL 32.
- **Reproductive and menstrual problems, including prostatitis, erectile dysfunction, infertility, pelvic pain, urogenital infection, metrorrhagia:** KI 10, LR 5, PC 6, SP 4, CV 6, BL 23.
- **Low back pain and stiffness:** KI 10, BL 40, BL 23, local trigger points and paraspinal stimulation a few segments cranial and caudal to the painful area. Palpate gluteal and piriformis muscles for trigger points. Investigate midline GV points that may address spine-based pain.
- **Knee pain or restriction:** KI 10, BL 40. Identify nature and source of pain, and surface affected. For popliteal pain, check for hamstring (biceps femoris) and plantaris trigger points.

Anterior knee pain may require a different approach, such as SP 9, SP 10, ST 36, and ST 34, with Xiyan.

- **Anterior cruciate ligament injury:** KI 10, SP 9, SP 10, ST 34, ST 36, BL 40, BL 55, associated trigger points. Consider myofascial work and laser therapy for dynamic (active) stabilizers of the knee.[14]
- **Posterior femoral cutaneous neuropathy:** Consider KI 10, KI 3, BL 40, BL 55, BL 60, and local nerve points at BL 54, BL 35, BL 36, and BL 37. Massage and laser therapy in addition to relax myofascial restriction, further improve circulation, and promote tissue recovery.

Evidence-Based Applications

- Laser acupuncture significantly outperformed sham laser for the treatment of **mild to moderate depression** with the following points: LR 8, LR 14, CV 14, CV 15, HT 7, SP 6, LI 4, and GV 20.[1]
- A case series reported that the following points, in combination with local tender points, offer benefit for the management of **back pain:** KI 3, KI 10, SI 3, BL 40, BL 60, BL 23, BL 25, BL 27, BL 29, BL 67, GB 44, and SI 18.[2]

KI 11

Heng Gu "Pubic Bone"

In the pubic region, immediately superior to the superior ramus of the pubis, 0.5 cun lateral to the anterior midline, level with CV 2.

Caution: Deep needling may penetrate a full bladder or injure the spermatic cord. See Figure 8-26 to examine structures within reach of a deeply placed acupuncture needle.

Spermatic Cord

- Contents include:
  - Testicular artery
  - Deferential artery
  - Cremasteric artery
  - Nerve to the cremaster (genital branch of the genitofemoral nerve)
  - Testicular nerves (sympathetic nerves)
  - Vas deferens (ductus deferens)
  - Pampiniform plexus
  - Lymphatic vessels
  - Tunica vaginalis
  - External spermatic fascia (an extension of the fascia that overlies the aponeurosis of the external oblique muscle)
  - Cremasteric muscle and fascia (a continuation of the internal oblique muscle and fascia)
  - Internal spermatic fascia (continuous with the transversalis fascia)

Clinical Relevance: Although one's acupuncture needle should not reach the spermatic cord, ST 29 overlies this important structure. As such, point activation with electroacupuncture, manual therapy, needle manipulation, or laser therapy may influence the function and blood supply of the cord's contents. That is, the vessels may dilate, the nerves may modulate, and myofascial elements relax. The result would likely lead to improved testicular function and reproductive capacity. See Figures 3-71 and 3-72 for two views of the anatomical relationships between ST 29 and the spermatic cord.

Fascia

- **Rectus sheath:** The rectus sheath represents the strong fibrous compartment incompletely enclosing the rectus abdominis and pyramidalis muscles. This fibrous compartment, in turn, arises from the aponeuroses of the flat abdominal muscles – the external and internal obliques and the transverse abdominal muscles.

Clinical Relevance: An epigastric artery rupture or rectus abdominis muscle tear can create a hematoma in the rectus sheath. Once considered rare, rectus sheath hematomata are increasing in frequency and severity.[1] More patients are receiving anti-coagulant medications and the population as a whole is advancing in age. Typically but not exclusively, the patient is an elderly female with acute onset of abdominal pain; examination reveals a palpable mass associated with a history of trauma to the abdomen. Missing this diagnosis may lead to unnecessary surgery for a false acute abdomen. In addition, incising the abdominal wall could exacerbate the bleeding by eliminating the natural tamponade the rectus sheath provides, leading to uncontrolled hemorrhage.

The consequences of rectus sheath hematoma range from self-limiting disease to patient demise. Delaying proper treatment might allow a small, initially asymptomatic mass to enlarge and cause signs of pelvic irritation accompanied by mild pyrexia and leukocytosis. Patients experiencing extensive hemorrhage into the rectus sheath exhibit tachycardia, tachypnea, sweating, and related signs of low blood volume.

In anti-coagulated patients with weakening of the rectus abdominis muscle, even apparently trivial trauma risks producing a rectus sheath hematoma. Activities such as coughing, sneezing, lifting, twisting, and other forms of exercise may tear a muscle or rupture a vessel. Paroxysms of coughing have been identified as a causative factor in over half of cases; patients with lung disease are thus at greater risk. Any needling of the rectus region could cause hematoma; even acupuncture has been cited as a cause of rectus sheath hematoma.[2]

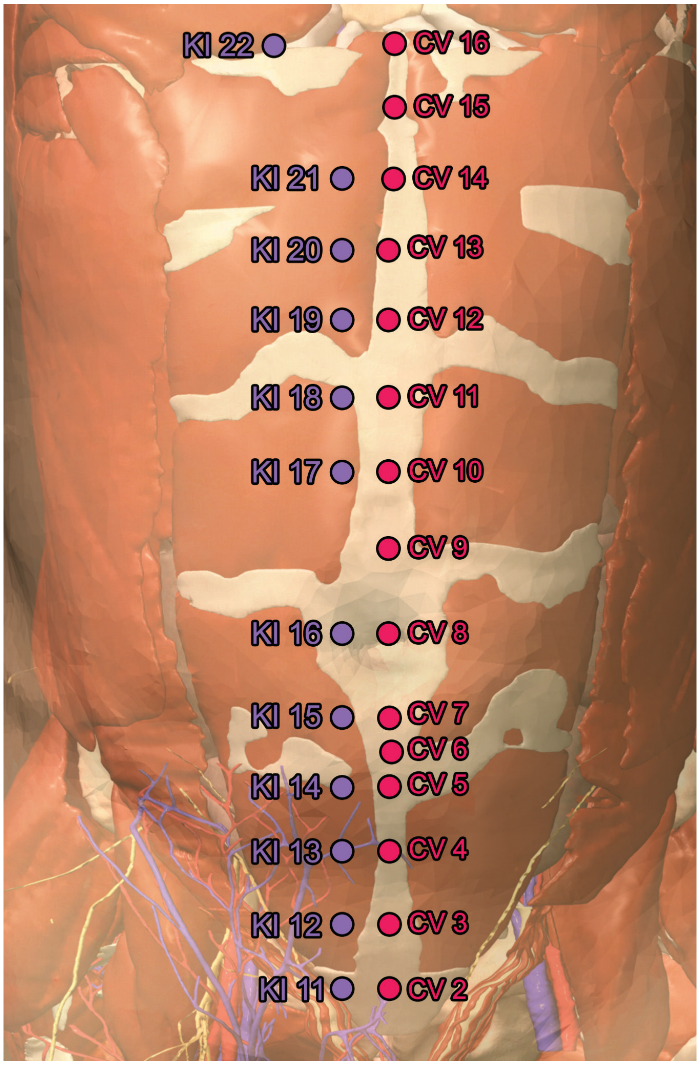

Figure 8-24. From KI 11, the "Pubic Bone" point, to KI 21, the KI channel finds a close affiliate in the CV line. Deep needling of KI and ST points in the caudal abdomen risk causing rectus sheath hematoma, a condition that may be misdiagnosed as septic shock, acute abdomen, appendicitis, and a host of other conditions.[18]

One case report described the signs that presented in a patient who developed a rectus sheath hematoma after acupuncture.[3] About four hours after acupuncture, a 37 year-old woman experienced sharp, focal, constant abdominal pain in the right lower quadrant. Abdominal examination and history were otherwise unremarkable, except for a vague and non-moveable tender mass in the painful spot without overlying ecchymosis. Carnett's test was positive, meaning that the pain increased when the supine patient lifted her head when the examiner palpated the mass. This test helps to differentiate abdominal wall pain from intra-abdominal processes and thus raises the index of suspicion of a rectus sheath hematoma. Additionally, when the patient contracted the rectus muscle, the outline of the mass became more prominent; a feature known as "Fothergill's sign".

Muscles

- **Rectus abdominis muscle:** Flexes the trunk by flexing the lumbar vertebrae; compresses abdominal organs. A diaphragm antagonist, the rectus abdominis muscle assists exhalation. The rectus abdominis muscle consists of a cranial and caudal portion demarcated by the arcuate line, landing about 5 cm caudal to the umbilicus. Transverse tendinous inscriptions or intersections further divide the muscle into segments, as illustrated through semi-transparent skin in Figure 8-24.
- **Pyramidalis muscle:** An inconstant muscle with varying incidence. Estimates of its presence in humans range from 3%[4] to 30%[5] or more. This triangular muscle resides cranial to the rectus abdominis muscle. It attaches to the pubis and the cranial pubic ligament, inserting onto the linea alba approximately halfway between the pubic symphysis and the umbilicus. It helps tense the linea alba when present.

Clinical Relevance: Caudal to the arcuate line of the abdomen, the rectus abdominis loses the protection its deep wall enjoyed cranial to the line. That is, the caudal aspect of the rectus sheath thins in this section of the abdomen as the connective tissue contribution of the obliques and the transversalis muscle dwindles. Thus, only a weak transversalis fascia and peritoneum separate the muscle from the abdominal compartment. This fact raises safety concerns for acupuncturists treating caudal abdominal acupuncture points along the CV, KI, ST, and SP lines, because deep needling carries more risk of entering the abdomen.

Trigger points in the rectus abdominis may refer to the back at similar spinal nerve levels. They may also cause somatovisceral discomfort including abdominal fullness, nausea, and vomiting. Rectus abdominis trigger points may arise from internal organ dysfunction, repeated episodes of vomiting or coughing, poor posture, stress, emotional trauma, motor vehicle accident, abdominal surgery, and over-exercise of abdominal musculature. Referred pain patterns from the abdominal oblique and transversus muscles can cause visceral symptoms such as "heartburn" and epigastric distress. In the caudal abdomen at KI 11, trigger points can incite feelings of bladder irritation and discomfort.

The pyramidalis muscle, when present but dysfunctional, refers pain to the umbilicus.

Nerves

- **Thoracoabdominal nerves (i.e., the ventral rami of the inferior six thoracic nerves):** These nerves innervate the anterior abdominal muscles and their overlying skin, as well as the periphery of the diaphragm. T7-T9 provide sensation to the skin superior to the umbilicus; T10 innervates the periumbilical skin; T11 and the subcostal (T12), iliohypogastric (L1) and ilioinguinal (L1) nerves supply the skin inferior, or caudal, to the umbilicus. Entrapment of these nerves within the rectus abdominis muscle causes rectus abdominis syndrome, leading to lower abdominal and pelvic pain that, in female patients, simulates pain from gynecologic conditions. More details about the subcostal, iliohypogastric, and ilioinguinal nerves follow.
- **Subcostal nerve (T12):** Supplies the skin in the region.
- **Iliohypogastric nerve (L1, some T12 fibers; nerve fiber origin is complex. Sensory nerve origins may derive from as cranial as T11 or as caudal as L3[6]):** The iliohypogastric nerve divides into anterior and lateral cutaneous branches. The lateral branch supplies the skin over the iliac crest while the ventral branch supplies the skin cranial to the pubic region.

The iliohypogastric nerve is the first nerve of the lumbar plexus.[7] The lumbar plexus forms from the ventral rami of T12 through L4. Most of the branches of the plexus either pass through or caudal to the psoas major muscle. The lumbar plexus gives off the iliohypogastric, ilioinguinal, genitofemoral, lateral femoral cutaneous, obturator, and femoral nerves.

The iliohypogastric nerve communicates extensively with the subcostal and ilioinguinal nerves. The iliohypogastric nerve pierces the transversus abdominis muscle. Some of its branches pierce the aponeurosis of the external oblique muscle. Communication between the genitofemoral and ilioinguinal or iliohypogastric nerves is common, causing overlap of sensory supply. Neurons from T11-L2 travel to the pelvic plexus via the inferior mesenteric plexus and hypogastric nerves.[8] Within the pelvic plexus, synapses take place between the plexus and postganglionic sympathetic fibers that project to the penis. Postganglionic sympathetic fibers consist of two types: cholinergic sympathetic and adrenergic sympathetic neurons. The cholinergic neurons function as vasodilators to the erectile tissue of the penis. Adrenergic neurons activate smooth muscle tissue in the epididymis, vas deferens, seminal vesicles, and prostate gland.

- **Ilioinguinal nerve (L1, occasionally with T12):** Branches from the ilioinguinal nerve supply the skin of the scrotum and labium majus by means of its anterior scrotal and labial branches, respectively. Other branches supply the skin over the proximal and medial thigh. The ilioinguinal nerve accompanies the spermatic cord or round ligament of the uterus as it moves through the superficial inguinal ring, on the way to its destination of either the scrotum or labium majus, depending on the gender of the individual. The ilioinguinal nerve is involved in the afferent limb of the cremasteric reflex, along with the genitofemoral nerve (L1,L2). Branches of the ilioinguinal nerve include the anterior scrotal in males and the labial in females. Damage to the ilioinguinal nerve has been called an "infamous complication of inguinal hernia surgery".[9]
- **Nerve to the pyramidalis muscle (T12 – L2, variable segmental supply):** The pyramidalis receives innervation from branches

of the lumbar plexus described as "border nerves" where the abdominal wall abuts the pelvic limbs. Nerves supplying this territory include the iliohypogastric, ilioinguinal, and genitofemoral nerves. The nerve to the pyramidalis exhibits wide variation in its origin, arising potentially from any of the three nerves.[10]

- **Spermatic ganglion:** Connected to the caudal (inferior) mesenteric plexus, likely sympathetic, supplying, at least in part, the testicular artery.[11]

Clinical Relevance: Nerves of the ventromedial abdominal wall form extensive communications within the transversus abdominis plane, lying between the internal oblique muscle and the transverse abdominis muscle.[12] Nerves of multi-segmental origin that reach the rectus abdominis and deep inferior epigastric artery form plexuses. Nerves from the plexuses run in a cranio-caudal direction in close proximity to the deep inferior epigastric artery. Anatomical investigations reveal that abdominal nerves communicate and branch extensively. The variability in spinal nerve origins for the ilioinguinal and iliohypogastric nerves translates into variable analgesia from nerve blocks for inguinal procedures such as herniorrhaphy.

Having multiple sites of crosstalk among nerves of the abdominal wall impacts anesthetic procedures involving nerve blockade as well as neuromodulatory approaches such as acupuncture and related techniques. That is, inputs designed to influence somatovisceral reflexes through Front Mu or other acupuncture points actually cause changes in several spinal cord segments rather than only one level, which works toward the acupuncturist's advantage by extending neuromodulation to a broader anatomic zone.

Abdominal or lumbar surgery may damage thoracoabdominal nerves and their branches, either during the initial incision or during closure with sutures. Sensorimotor loss or nerve entrapment may follow.[13] Entrapment of the thoracoabdominal nerves has been identified as the most common cause of abdominal wall pain.[14] The nerves become entrapped where they move through a fibrous tunnel and where soft tissues such as muscle tension, fibrous bands, or fascial restriction cause compression at vulnerable turning points. Abdominal scars can further nerve compression/entrapment. Acupuncture may benefit these patients by releasing tension in the tissues, thereby freeing the nerves.

When abdominal surgery injures nerves traveling through one or more planes of the abdominal wall, paresis of the rectus abdominis muscle may ensue, followed by bulging of the abdominal wall.[15] Paresis of the abdominal wall may cause large swelling and mechanical complaints. Considering the benefits of acupuncture and related techniques for peripheral nerve injury, ilioinguinal nerve injury would likely respond to neuromodulation unless the nerves were severed completely. Chronic pain syndromes that take hold following iliohypogastric or ilioinguinal nerve injury during open inguinal hernia repair or gynecologic surgery should also be addressed with neuromodulation, in addition to adjunctive abdominal support and multimodal analgesia.

Vessels

- **Superficial (inferior) epigastric artery:** Supplies the subcutaneous tissue and skin in the area superior to the pubis.

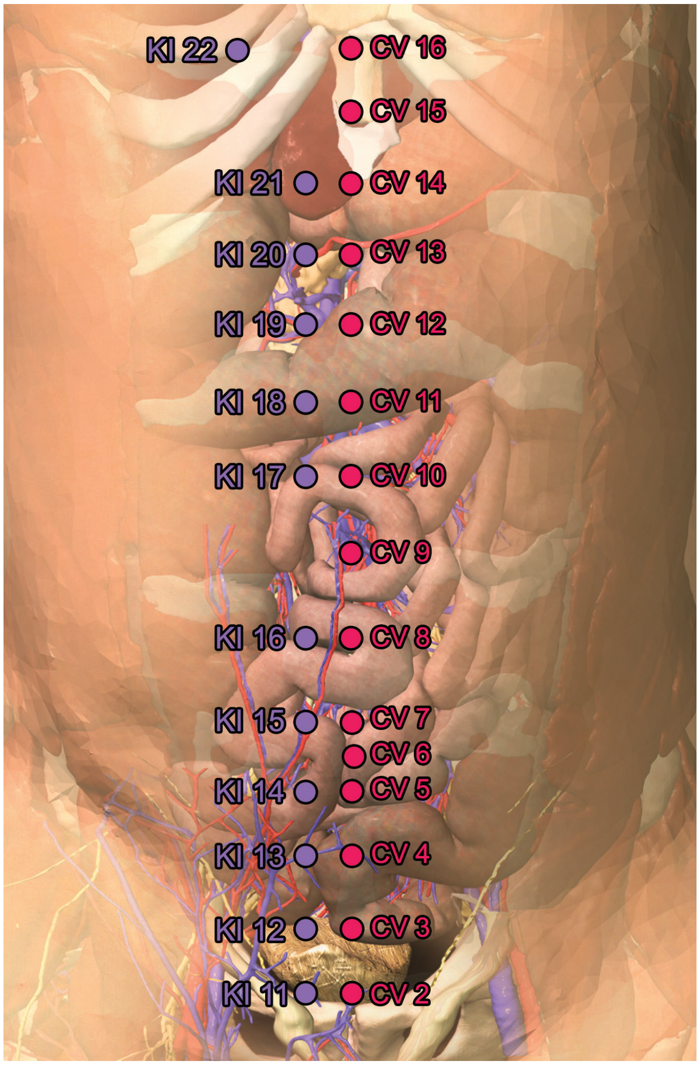

Figure 8-25. The organs beneath the KI line over the abdomen span from the pubic bone (the point's namesake) and urinary bladder at KI 11 to the pylorus at KI 21.

- **Inferior (deep) epigastric artery:** Supplies the rectus abdominis muscle and the medial portion of the anterolateral abdominal wall. A branch of the external iliac artery. Anastomoses with the superior epigastric artery within the rectus sheath near the umbilicus.
- **Superficial (inferior) epigastric vein:** The superficial epigastric veins provide collateral circulation routes for abdominopelvic venous blood. These valveless veins offer an additional route for venous blood to return to the heart in cases of inferior vena caval obstruction or ligation. Usually, the superficial epigastric vein is a tributary of the great saphenous vein.
- **Inferior (deep) epigastric vein:** The inferior epigastric veins are tributaries of the external iliac veins. They anastomose with the superior epigastric veins inside the rectus sheath. These valveless veins can, like the superficial epigastric veins, act as collateral routes for abdominopelvic blood return to the heart. Collateral venous connections provide alternate routes for venous return from the lower extremities, by bypassing an obstructed or ligated inferior vena cava. Venous blood instead drains into the internal thoracic, subclavian and brachiocephalic veins and, from there, into the superior vena cava.

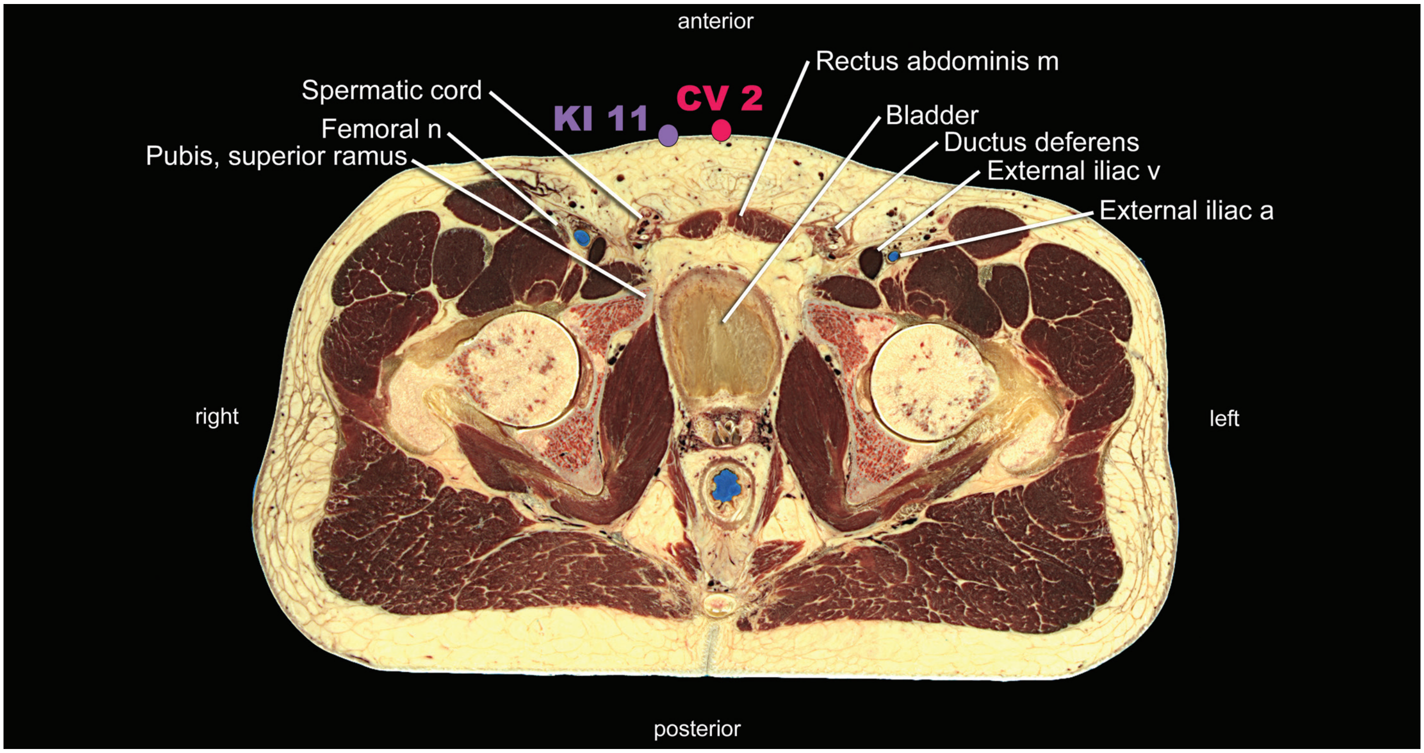

Figure 8-26. The organ targets when including KI 11 in acupuncture protocols become apparent in this cross-section. They include urinary, reproductive, and abdominal wall musculature. Although this individual did not exhibit a readily discernible pyramidalis muscle, trigger points in this or other abdominal wall musculature can cause referred pain symptoms that mimic visceral dysfunction, including diarrhea, urinary tract discomfort, and appendicitis.

- **Superficial external pudendal artery:** A branch of the femoral artery, the superficial external pudendal artery crosses the spermatic cord and supplies the skin on the lower abdomen, the penis, and scrotum. The superficial external pudendal artery anastomoses with branches of the internal pudendal artery.

The deep external pudendal artery also arises from the femoral artery, but in contrast to its superficial counterpart, passes across the pectineus and adductor longus muscles to supply the skin of the scrotum and perineum. The deep external pudendal artery anastomoses with scrotal branches of the perineal artery.

Clinical Relevance: The inferior epigastric vessels supply the rectus abdominis muscle in this region; further cranial, they anastomose abundantly with the superior epigastric vessels within the confines of the rectus sheath on its deep surface. Rectus sheath hematomas occur in this caudal section of the rectus compartment most frequently. A predilection for the caudal compartment manifests due to the degree of muscle shortening and contraction that takes place at this level as well as the absence of a strong caudal wall. Blood vessel attachments to the muscles are also fixed in position, allowing little room for stretch. Violent muscle contraction or trauma exposes this vulnerable territory to vascular injury and potentially life-threatening hematomata within the sheath. Sudden onset of abdominal pain and swelling of the abdominal wall may arise from an inferior epigastric artery rupture in a previously asymptomatic patient. Coughing or anticoagulant therapy increases the risk.[16] Femoral catheterization may iatrogenically injure the inferior epigastric artery and thereby produce hemorrhage and cause serious morbidity.

Indications and Potential Point Combinations

- **Pelvic and reproductive problems, including oligospermia, retracted penis, priapism, pain:** KI 11, CV 2, CV 6, ST 29, SP 30, SP 12, SP 6, BL 32.
- **Urinary problems, including dysuria, enuresis, retention:** KI 11, CV 3, SP 6, BL 28, BL 32.
- **Distension, dysfunction, and/or pain of the lower abdomen:** KI 11, ST 25, ST 36. Check for trigger points in the abdominal muscles, as reciprocal somatovisceral and viscerosomatic connections between the muscles and abdominal organs may produce symptoms that closely mimic visceral or somatic dysfunction.
- **Back pain:** KI 11 as an attachment trigger point in the rectus abdominis muscle may refer pain in a band-like fashion to the sacral and cranial gluteal regions.
- **Midline post-incisional pain or continued scar irritation:** KI 11 and other points near and around scar. Direct needles toward scar but insert into normal tissue. Employ manual therapy treatment to free underlying soft and connective tissue. Consider laser therapy.
